BREEDING IN-AND-IN.—It has been proved by numerous facts, that multiplication by the son and mother, or between brothers and sisters, is a powerful cause of the degeneracy of races as much with regard to the fur of Rabbits, as their fecundity, vigour

and health. Indeed Rabbits of one uniform colour, that multiply in their own family, offer from the third generation, white spots on the fur, prejudicial to the value of it. Fecundity also insensibly diminishes, and weak consumptive Rabbits are produced, subject to internal derangements, and seldom living over the first moult, but usually dying off at from four to six weeks old.

HARE RABBITS.—Few are ignorant of the unsuccessful attempts of the many celebrated naturalists to obtain hybrids, by the crossing of the Hare with the Rabbit. This want of success appeared so conclusive, that all fresh attempts had been given up. It is thought, by some persons of good authority, that the wildness and cowardice natural to the Hare has been the only cause; indeed, if you bring up a male Hare in the company of Rabbits, male and female, he usually remains timid and wild, and in several establishments has been kept for years without manifesting any desire of propagation. It seems that this is not the case by attempting to obtain hybrids between the male Rabbit and female Hare, who is not so wild and timid as the male Hare.

This opinion, which is that of several French writers and is mentioned by M. Didiex, has been put in practice with success in the department of the Cher, at least we are assured so by M. Goubaul, Professor of the "Ecole Imperiale Veterinaire d'Alfort." He says that he has seen in one single establishment, nearly three hundred hybrids of this kind, that had the valuable faculty of reproduction among each other, and that their flesh appeared infinitely superior to that of the Rabbit.

The hybridising of Rabbits has been tried at the Zoological Gardens in London, this last season without success; but the superintendent informs me he has no doubt that he shall be able to produce them in the coming spring.

GESTATION.—Pregnancy continues from thirty to thirty-one days, and a memorandum should be made in the stud-book to indicate the day of the doe's fecundation, in order to separate her from the young she is suckling at least a week before to strengthen her, and clean the hutch out and prepare by giving litter to make her bed for her new family. If she is suckling and pregnant at the same time she must be fed with rich and succulent food and occasionally a little salt be given to increase her appetite; of food let her have as much as she likes to eat.

Females that fill the double office of suckling and breeding at the same time, are often so thirsty, that they devour one or two of their young ones to allay thirst by sucking the blood. It is then indispensable to give them at least twice a-day, a good handful of green stuffs, and about half a quart of water once a-day. The captive Rabbit does not know how to be sober with water, and suckling mothers must be rationed. With respect to drinks, I have reared several litters of very fine strong Rabbits in the winter when green food was scarce, by giving only milk to the mothers, as much as they liked to take—in fact, they had a trough affixed to the hutch, and which was filled each time they were fed with other food.

SIMULATED GESTATION.—Rabbits that have not become pregnant frequently offer the physiological phenomena of a real gestation. They prepare their nest, their teats swell, and the secretion of milk takes place. They have been known to adopt, when the opportunity offered, strange young. Harvey, the immortal discoverer of the circulation of the blood, says that he has seen and observed this physiological phenomenon in Rabbits.

MISCARRIAGE.—Too much violent exercise, chiefly from fear, causes often a sudden miscarriage. It is true that it is seldom dangerous, and the Rabbit may again receive the male a few days after. Violent claps of thunder are one cause of abortion. Frozen green food, wet or too watery green food, is often a cause that admits of prevention.

DELIVERY.—When the Rabbit is strong and vigorous she is delivered easily and without violent pain. This phenomenon is owing to her particular organisation. The successive births sometimes last twenty-four hours. During parturition the Rabbit loves quiet and secrecy, and it is for this reason that it is customary to cover the door of the hutch over with a cloth from the twenty-eighth day of gestation. Rabbits frequently die from a laborious birth, or from weakness, the result of leanness or of bad food, even from too watery green food given during any length of time.

SUCKLING.—Four or five days before the birth, as I have before said, you should renew the litter and leave the Rabbit alone in her hutch to prepare her nest. Delivered, she closes

the opening of her nest and watches with solicitude by the side of her new family. She suckles them several times a-day, but chiefly at night. The Rabbit loves to be delivered in secret, and she also likes to suckle her young in secret; if she is surprised in this important function of maternity, she starts away suddenly and drags with her several little ones out of the nest. The mother does not replace them, and they perish with cold until the feeder does it for her.

WEANING.—At the age of five or six weeks the young should be weaned by removing them from the mother. The young are much finer if left till seven or eight weeks old with their mother; but in that case you diminish the number of young, by allowing the mother to bear less frequently. The weaned Rabbits should be placed with others of the same age, if possible, in spacious, clean, warm hutches, with plenty of broken straw for their bed. Great cleanliness assists their development. They should have tender, tonic, succulent food, a little barley-meal four times a-day and whatever they leave may be distributed to the older and less dainty Rabbits.

(To be continued.)

SUPER-POSING.

THE upper of two hives united will at the end of the season contain the bees. Such is a fact, and

"Facts are stubborn chicks that wanna ding,
And daarna be disputed."

and which no amount of evasion or clever theorising on the part of "A DEVONSHIRE BEE-KEEPER" away from the point can ever controvert.

This case has got so enveloped in a mass of verbiage that your correspondent seems fairly to have lost sight of the point at issue. Stripped of all such, it stands forth simply this.

"A. W." had two hives he proposed to unite (page 38) for the sake of getting the bees to vacate the lower unwieldy box so that he might remove it—"in the cold weather"—thinking, naturally enough, that confining them to the upper lesser hive would enhance the probability of the wished-for swarm the coming season. He was told, in answer, that they would not so ascend; but "descend into the lower hive." This reply being quite at variance with all my experience of such cases, I could not resist fraternally expressing a contrary opinion, and quoted the last parallel case from my own apiary by his benefit, page 78. That opinion was flatly contradicted by "A DEVONSHIRE BEE-KEEPER," and I most cordially agree to differ with him thereupon; and seeing that one of the most experienced bee-keepers in the Kingdom, after forty years' practice of storifying, involving continually such cases, has failed to convince him of his error, my attempting so hopeless a task longer would be but a useless encroachment on your valuable space.

I would not again have alluded to this subject were it not that your correspondent has thought proper, to ascribe as my opinion, "that bees are disposed to adopt the upper compartments of storified hives as their breeding-place." Were it not that he is a tolerably sharp observer of the bee articles in your back volumes, such an expression would be more excusable; but did he overlook such at the moment he penned the sentence, his beguiling a leisure hour in perusing these articles will supersede the necessity of my quoting here the frequency with which I have expressed the inverse opinion. Such an opinion he puts forth as mine. I never gave utterance to, nor wrote a line that could be twisted to bear such a construction. I am, therefore, forced to the conclusion that the printer must have inadvertently substituted the word "breeding" for "feeding place," the one having some connection to the subject, the other manifestly none.

Your correspondent also unhappily quotes the "tier of ekes" I referred to as an argument in his favour. The sequel of that story showed that the bees, instead of "hatching out any brood that might be in the upper box," and descending into the "tier of ekes," agreeably to his theory, hatched out the brood in the ekes and ascended into the upper box; so that these were removed entirely empty, and their combs have served for a considerable time another useful purpose as detailed in page 159. Altogether from the very peculiar mode of reasoning adopted by "A DEVONSHIRE BEE-KEEPER," I for one must decline entering the lists against him for the future, however *outré* the opinions he may put forth.

When Mr. Fox's attention was drawn to this case, had it been

set before him in its real merits he could not have failed to perceive that breeding honey, or pollen storing, at such a season, and in any way to affect the desired object, was quite foreign to the subject; it altogether hinging on what part of the hive the inmates prefer to adopt as their winter quarters; and that correspondent saved from the awkward dilemma of employing arguments to confute a brother apiarian, which in more appropriate circumstances he had perhaps too frequently adduced.

While on this subject, for the benefit of the novice, I may mention, that by this most productive of all systems of bee-keeping, the storifying, the mode "A. W." proposed to pursue, is practised at the end of every season with almost every hive, the lower portion so soon as vacated is removed, the slides run in, and the door shut, and the hive set upon a board with the view of excluding the air for the better preservation of the comb, and an empty shallow eke substituted in its stead, so that there may be always a free circulation of fresh air below to prevent dampness. I found on more than one occasion when I had neglected this useful rule, my little favourites, sore pressed by long confinement during frosts, converted the lower compartment to a necessitous purpose, served by a smaller chamber in larger mansions. The empty comb is returned when the hives appear crowded the following season.

That bees ascend to occupy the upper portion of their hives during the dormant season, amounts to a truism in storifying, and amply confirmed to the most casual observer, by a glance at the loaded upper boxes or tops of comb, that as surely as the wintry frosts send up the occupants of the summer box to town, so surely will they drive up our little favourites to take possession of their comfortable, well-stored, upper home. The same attractive influences of summer sun and opening flower that prompts the maternal longings to go down into the country, and re-occupy the old residence, impels the royal mother to go down into the vacated summer mansion, causing it once more to resound with the pleasant hum and busy stir of her more numerous progeny and larger establishment.

Presuming this subject now fairly exhausted, it must afford you some satisfaction in return for the space its discussion has occupied; you being able, in all times coming, to refer future querists, as to such cases for full details, to the now notorious "A. W." and "A. R. FRESHWATER BEE-KEEPER."

P.S.—Although, I by no means advocate introducing food as a rule directly into the combs, I never experienced any bad effects in those cases I tried it, and do not know anything of the chemical changes "A DEVONSHIRE BEE-KEEPER" mentions. My exemption from such may arise from having had recourse to this mode at a time when the heat of the laboratory was sufficient to enable the little chemists to secrete wax in abundance, thereby allowing its being sealed up at once. If introduced in large quantities and left exposed it might possibly sour. The term "waste" your correspondent emits at, if my memory serves me, was formerly employed by himself.

DIARY FOR THE DAIRY, PIGGERY, POULTRY-YARD, PIGEON-HOUSE, AND APIARY, FOR 1862.—This very useful annual (edited by a well-known "Essex Amateur," and published by Routledge and Co.) has again issued from the press. It combines, as usual, an account-book and memorandum-book for all the expenses and proceedings of those departments in rural economy; besides calendars of the work especially desirable to be attended to in each month; remedies for diseases; hints as to feeding the animals, &c.

LIGURIAN BEES.—The hive first introduced into Scotland swarmed thrice in the beginning of June, and these young swarms again produced other three large swarms which increased them to seven, including the original hive, all of which are well stored with food for their winter's keep; and these have been still further increased by artificial swarming; so that Mr. J. Swan, of Dunse, who introduced them here, has now eleven strong hives of Ligurians in his apiary, to which may be added another hive that has turned out an Anglo-Italian. These twelve have been all reared from the one during the present summer; and, notwithstanding this extraordinary subdivision, they are heavier than those of the other variety, which have been allowed to work in the usual way. Premising that the object in view was the multiplication of stocks rather than the produce of honey, it will thus appear that they have proved themselves worthy of an introduction into our country. This is the first

entire summer which the Italian bee has had in Scotland; and, in so far as they have been tested, they have proved their superiority, and are likely, ere long, to take the same position in Scotland that they are doing on the continent—viz., superceding the original variety as they can be obtained.—(*Scottish Farmer and Horticulturist*.)

PARTHENOGENESIS IN THE HONEY BEE.

I AM obliged to "INVESTIGATOR" for his suggestions as to the best means of verifying the phenomenon of parthenogenesis in the honey bee, and shall be glad of his valuable assistance in these researches. In fact, I am desirous of appealing for aid to all the apianian readers of THE JOURNAL OF HORTICULTURE, who may have the opportunity, and are able to devote a little time to this investigation.

I have not myself very much faith in the value of the diurnal observations recommended by "INVESTIGATOR," but should prefer insuring the virginity of queen bees by interposing an insuperable obstacle to their fecundations. This may be effected either by breeding them early in the spring when no drones are in existence to impregnate them, or late in the autumn after all drones have disappeared. The same object may be secured during summer by adopting Huber's plan of a contracted entrance, which will not allow the queen to leave the hive; or clipping her wings as soon as she emerges from her eradic might be tried. Whenever a queen bee has been produced by either of these means which proves incapable of laying any eggs but those of males, I shall be happy to dissect her, and confirm by microscopic examination the fact that she is really a virgin mother.—A DEVONSHIRE BEE-KEEPER.

I NOTICE the remarks of "INVESTIGATOR" in your Journal of the 26th of November, and, in reply, beg to inform him that the drone-laying queen there referred to, was closely examined both morning and evening until the 22nd of July, and no symptom of impregnation was ever observed. I then left home for a week, but found no eggs deposited in the cells on my return.

I then commenced to feed the hive liberally, and the workers at once began to import pollen, and the queen almost immediately began to lay. If the stimulus had been given at an earlier period, the excitement and heat generated in the hive would probably have induced the queen to leave home and go in quest of drones.

The close examination of the queen, however, is really of little or no moment. In this case she unquestionably laid many eggs in worker-cells, all of which produced drones, and this circumstance at once led me to believe that she was unimpregnated, and I sent her to "A DEVONSHIRE BEE-KEEPER," in order that he might, by dissection and microscopic examination, discover if she was still a virgin. The examination proved most indisputably that she was unimpregnated, and thus clearly demonstrated the truth of the doctrine of parthenogenesis in the honey bee.

If this queen had had intercourse with a drone, the spermatheca could not have failed to exhibit traces of impregnation, but its contents were found to contain a perfectly clear fluid (exactly the same as those of a virgin queen) without the slightest trace of any of the countless myriads of spermatozoa invariably discovered in the spermatheca of a fertile queen.

We can only make conjectures as to the cause of her remaining unimpregnated; and the reasons assigned, taken in conjunction, appear to account pretty satisfactorily for so unusual a circumstance. If the weather had been more favourable or the colony more populous, I doubt not she would have left the hive and have been fertilised.

Every one conversant with bees is aware that a weak hive is much later in breeding than a populous one, and the shape of a unicorn-hive, by preventing the clustering of the bees, is particularly ill adapted for encouraging the laying of the queen, and I have always found queens in this hive discontinuing laying very early in the season, whilst these in more commodious hives were still laying pretty freely.—J. E. BRISQOE, *Wolverhampton*.

WORLD "A DEVONSHIRE BEE-KEEPER" say if the "fatherless bairnies" (drones, of course, I mean) bred from virgin queens are capable in their turn of propagating the species, or are such anomalies in Nature incapable of production like mules?

Should they be so constituted as to reproduce their kind, would it not be desirable your Devon correspondent keeping, say, a couple of stocks with drone-producing queens at their head to

keep up a supply of males all the year round, enabling him to fertilise young queens much earlier and later in the season than formerly, and yet satisfactorily fulfill his engagements to his subscribers?—W. J.

[There is no doubt that drones bred by virgin queens are perfectly capable of propagating their species. In fact, I believe that the one whose post mortem examination was recorded in page 97 was the progeny of a virgin. The maintenance of two stocks with drone-breeding queens at their head would probably be too great a tax on the resources of my apiary; but I fancy I have one very handsome Ligurian queen of this description, which will be valuable in the event of an unpropitious season again leading to an indiscriminate slaughter. She will not, however, be of much use in protracting the season for queen-breeding, since natural drones are usually present in sufficient numbers as early and as late as the weather is sufficiently favourable.—A DEVONSHIRE BEE-KEEPER.]

BIRDS AND INSECTS.—At the late agricultural meeting at St. Gallen, in Switzerland, Baron von Tschudi, the celebrated Swiss naturalist, dwelt on the important services of birds in the destruction of insects. Without birds, said he, no agriculture and vegetation are possible. They accomplish in a few months the profitable work of destruction which millions of human hands could not do half so well in as many years; and the sage, therefore, blamed in very severe terms the foolish practice of shooting and destroying birds, which prevails more especially in Italy, recommending, on the contrary, the process of alluring birds into gardens and cornfields. Among the most deserving birds he counts Swallows, Finches, Titmice, Redwills, &c. The naturalist then cites numerous instances in support of his assertion. In a flower garden of one of his neighbours three lily rose trees had been suddenly covered with about 2000 tree lice. At his recommendation a Marsh Titmouse was located in the garden, which in a few hours consumed the whole brood, and left the roses perfectly clean. A Redtail in a room was observed to catch about 900 flies in an hour. A couple of night Swallows have been known to destroy a whole swarm of gnats in fifteen minutes. A pair of Golden-crested Wrens carry insects as food to their nestlings upon an average thirty-six times in an hour. For the protection of orchards and woods Titmice are of invaluable service. They consume, in particular, the eggs of the dangerous pine-spiders. One single female of such spiders frequently lays from 600 to 800 eggs twice in the summer season, while a Titmouse with her young ones consumes daily several thousands of them. Wrens, Nuthatches, and Woodpeckers often dexterously fetch from the crevices of tree-bark numbers of insects for their nestlings.—(*Once a Week*.)

OUR LETTER BOX.

LENGTH OF RABBIT EARS (*D. E. M. S.*)—First-prize lop-eared Rabbits usually have ears about 22½ inches long from tip to tip, and 1½ inches broad at the greatest width of each.

JAY STOPPING SQUIRRELS (*J. J.*)—I would advise a tonic for the Jay, put some smelt's forge water in his drink. To strengthen him, give him eggs and young mice, or birds to eat—such food he would get when wild. Dust some sulphur among his feathers, well into the quills all over his body, and wash him once or a little brandy and milk, is better than the sponge cake you give. Examine the cage to see if there any mice in it, and if so, get rid of them and fill the cracks with sulphur, and dust some among the birds' feathers. It may be the bird has vermin or a swelling of the crop-gland.—E. P. B.

FEEDING AND UNFITTING BEES (*A Beginner, Settle*)—Your story reminds us of an equitation novice, who, intending to ride ten miles in a certain direction, should commence by proceeding five miles in the wrong road, and then proceed to ride half-a-dozen miles across a difficult country with the view of regaining the right track. Could we be by your side to instruct you where to save your good steed, and where to ply whip and spur without stint, you might probably pull to match; but under present circumstances we know of no instructions that we could give which would insure you against "coming to grief." Do not, therefore, attempt to unite your two stocks, or purchase another in a straw hive unless with the intention of allowing it to swarm; but rather buy a good swarm of two, and stock your depriving-hives in the natural way. We do not think the discussions you give sufficiently long for street-boxes. Mr. Woolbury has none less than 12 inches square by 8 in his deep, and prefers a larger size for Ligurians.

A-BEET FOR FLIES (*A Instant Bee-ee*)—South-east is the best aspect for bees; but we do not consider it a point of primary importance. Separate the bees from the bees whose comb the bees used the comb has a little healthy part (from a preceding brood, or some other change of comb), she has forgotten her combal aim.

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last thirty-four years, the average highest and lowest temperatures of the three days are 44.7° and 33.6° respectively. The greatest heat, 55°, occurred on the 18th in 1819; and the lowest cold, 7°, on the 19th in 1859. During the period 125 days were fine, and on 113 rain fell.

PRESERVING ICE.

N the winter of 1847, and again in 1848, when I ventilated the first ice-house by undoing the doors in the side-passage, by getting rid of the straw which blocked the passage, and by

making a man-hole in the crown of the vaulted-roof over the ice, I made an attempt at thorough ventilation, by

letting in a current of air at the bottom of the ice through the waste-drain; but that I could not accomplish, because the waste-drain for that ice-house went straight into a deep sand-bank. From that time I never said a word about ventilating an ice-house through the waste-drain until last week, for two reasons, the first of which was the difficulty of doing it, such as I had experienced; and the second, the apprehension that no reader would then believe the plan was practicable, owing to the wrong notions which existed on the subject of keeping ice.

The one-half of the plan, the top ventilation, was adopted, however, in hundreds of instances, both here and in America, and in every instance the plan succeeded so far. Mr. Fish referred to it and to its success not a month back, and yet the probability of it, the possibility of such a plan succeeding, and the credibility of the writer have been since called in question. Such is the effect of the want of teaching common things in our schools, and such was the reason why I gave a glimpse of the natural history of ice, so to speak, and my own acquaintance with it last week. I shall now proceed to the second head of the subject, and show you how Nature wastes ice on a grand scale. The first head was how Nature preserves ice by a strong current of warm air, by a hot breeze under a tropical sun, or in the full face of an Italian sky.

Neither in the Gulf of Mexico, nor on the slopes of the Italian Alps, does the sun always shine, or the hot breeze dry up every particle of moisture which it comes in contact with; or, in other words, the essentials of the grand secret of preserving ice, by keeping the surface of it perfectly dry, are not always, or in all places, in full play in the lap of Nature. There are dull days, muggy weather, fogs, mists, and rain, and not a breath of air stirring. Each and all of these conditions of the atmosphere waste the ice in Nature's stores at a fearful rate, and men on a small scale imitate the very process by which Nature loses her icebergs, and her 10,000 tons of ice snow yearly, under the false notion that the process will do the very contrary, if they only hide it from the face of day in the bowels of the earth, in an ice-house which is not most thoroughly ventilated, even not ventilated at all. There has not been a single theory since the flood so utterly at variance with the laws of Nature

in the matter, as that which presupposed that ice could be kept from melting if the air could be kept from it, unless it was the very next step in the process—that of placing straw between the walls and the ice, the effect of which could only be to accelerate the waste. But the idea of mats or that any textile fabric could preserve ice placed next to brick or stone wall, was four times, if not six times more out of reason, than the idea about the straw. Any thing or substance which will imbibe moisture should never be placed against the sides of a mass of ice. The best stock-bricks will soon get wet through and through from the melting of the ice, and from the vapour which rises from the melting; therefore, the best bricks are not one-half so good to build an ice-house with as hard impervious stone, such as the old ice-houses in Scotland have been built with.

To have a column of pent air between two brick walls, as in a hollow wall for keeping ice, is a very feasible idea at first sight, but on second thought it is at the same time a most unphilosophical one, and such a thing should never be. The reason is this: pent air between two dry walls is as thirsty as a baker's oven, and is as capable of sucking in moisture as a dry sponge: the wall next the ice is soon damp when the ice begins to melt; the confined air sucks up this damp till it is charged with it to the point of saturation; and as the ice lowers down by waste, the wall above the ice-line would dry in one-quarter of the time if that volume of damp air had not been behind it; and be it always remembered that so many degrees of damp will waste more ice than twice as many degrees of heat.

If you could disabuse the public mind of the tremendous error that heat is more destructive to ice than anything else, there would be no very great difficulty in converting them to the truth; but as long as that most absurd notion is uppermost, it must be an up-hill work to melt their mood by plain facts—facts such as that saturated air at 50° of heat will melt ice faster than thirsty air would do at 96°.

I have seen ice under the two points, or the 50° and the 90°, under the conditions stated; and where the moist air at 50° impinged on a vault of ice, the whole surface of the vault was dripping fast as a shower-bath, and at the very same moment 96° was playing on another part of the same mass, and it was hardly damp to the touch. Perhaps that is as curious a thing as you have read of this month, and to explain how that could be is another heading in the natural history of ice. It is also the most convincing proof we have from Nature, that the general ideas about keeping ice which prevailed formerly were entirely and altogether wrong.

As icebergs are difficult and dangerous to get at, I shall explain this head of the subject by another reference to the Italian and Swiss Alps, where tourists go from here every season, none of whom will be able to say the account is not true to Nature. In all mountainous countries the snow is drifted in winter into large hollows, gulleys, or valleys, in immense quantities. There it is iced or turned as hard as ice itself—so much so, that if

a squadron of cavalry were exercised on the flat surface of a large mass of snow in July or August you could hardly trace their footprints ten minutes afterwards. On a gently sloping face of snow the horses could not stand at all, unless they were shod for that very purpose. We shall say that mass of snow was only 30 feet deep at the time, and would measure just one acre. The whole of that acre we shall say is exposed to a hot breeze of 96° at the end of July. I said already the moisture of the whole surface under the conditions stated would not damp a cambie pocket-handkerchief. But in other parts of this same mass of ice and snow the temperature is barely 50°, and there it is wasting in a shower much heavier than any storm shower ever seen in this latitude. I was never there to know; but the natural history of ice and snow is the same in all countries and climes, and I have said that I had seen the sight under the 96° and the 50° as here stated. Any one who chooses may see the sight in this island, but we shall keep to the route of mountain travellers on the Alps, or midway between the lowest range of remaining snow in August and the limits of eternal snow; and in every one of the wreaths of snow which we there and then meet with, we shall see this sight—a burning sun and a stiff breeze keeping the ice-like surface dry as a feather-bed; and a much lower temperature without sun or wind wasting the same mass, it may be right below the spot we are standing on. That spot is the right place to explain a very common error. Suppose the air was now suddenly chilled, and the breeze was at the freezing-point—32°. Many would say that, of course, would save the ice from melting; so did the breeze at 96°. But the truth is, the air at 32° does neither cool nor harm to the ice on the mountain side or in the ice-house.

To explain how the high degree does not melt the surface of the great mass of ice and snow, and how the low degree melts it so much as is said, will at the same time explain the cause why ice does not keep better in old-fashioned ice-houses. For the cause of the air being so high as 96° in some places, we shall suppose the mass of snow to have been drifted into a great hollow immediately in front of a run of high rocks which reflect the rays of the sun, as a garden wall reflects them on a Peach-borler. And to make the explanation more familiar, we shall suppose the hollow to be in the form of a railway cutting in front of a tunnel, and that the snow fills up this cutting high as the banks. In that form and position the edges at either bank, being the thinnest parts of the mass, are melting fast. The water from this melting runs down under the snow, forming little tunnels in the body of the snow. No current of air can rush down the little tunnels because there is yet no opening for it below; but the little tunnel itself is full of air, of course, and the chill from the snow has reduced it to 50°. The air is now saturated, and it becomes a vapour, and when air is vaporised, as one might say, it melts ice faster than a brisk fire. By this time, or by the end of July, the tail of the snow wreath, or that low part of it down where the rails would be in a railway cutting, is melting at a rate ten times more destructive than in the little tunnels up along the sides, and the melting there is wasting the mass exactly in the form of a railway tunnel. At first, when the water from the melting of the lower end of both banks meets in the centre of the roadway, it forms a little pool there, the vapour from that little pool soon makes an indent in the very centre of the deepest part of the snow not bigger than a man's hat, the confined vapour caused by the great heat melts the snow right and left and over the top in equal proportions, and in time a tunnel is thus formed as wide and a great deal higher than a railway tunnel; and in a hot day you could not see 10 yards before you in such a tunnel with the misty vapour, and the fast falling of huge drops from every inch of the vault, and the air chilled down to 50°, while 96° are playing over your head, out and up on the surface, between the banks, which surface is just as dry all this time I have just said. I have seen the like of this scores and scores of times, but I never saw a better place for boys to play at ducks and drakes in than a snow tunnel in hot weather. But there is a much grander sight sometimes for boys of another age—the tunnel comes up abruptly to a steep knoll rising from the bottom of the great hollow. The snow next to this rising ground is much softer than when it is far from it, and it goes before the volume of misty vapour faster than before. The tunnel now takes a perpendicular direction, and before it reaches the surface a large portion from both sides of the hollow collapse and tumble down, the one against the other, with a fearful crash, which when reverberated all round the mountains is grand indeed.

But the rest of the story is soon told. From the moment this collapse makes way for a rush of wind to pass up the tunnel, the dripping of the sides ceases entirely, the tunnel was ventilated, and that saved it in that direction. Ventilate the ice-house through the waste-water drain and you will see the result on a minor scale. D. BEATON.

WINTER FLOWERS IN ROOMS.

As some of your readers took an interest in the little hints I sent some time ago to your Journal, on planting bulbs for the ornament of a room in the dreary season for flowers out of doors, I think that, perhaps, they may like to have three or four more hints as to carrying on their culture.

I shall speak in this letter only of such bulbs as are quite unforced, unless where it is otherwise particularly expressed.

First, I must say that many planted on the 11th of September are now showing blossom. Scillas and Crocuses, and especially Narcissi; and as Narcissi grow up often faster than we could wish, I find that the extremely vulgar practice of placing a line of glasses along the window-bar (on the centre bar, I mean, where the sashes meet), so remarkably beneficial to the plants at any rate, that it is not in a gardener's nature to refrain from adopting it. In my plant-case a Narcissus (Double Roman), is just coming out, but I find that forcing increases leaves as rapidly as flowers, unless the plant stands at least 4 inches from the glass. The fine straight leaves look well themselves, however. Red Tulips and White Crocuses are now arranged in groups together for flowering; and these also are being kept moist and very light. My best dishes stand upon the floor in a window which opens to the ground, as thus they obtain a light so much clearer.

The Crocuses are actually indicating colour with at present scarcely any attempt at leaves—the most satisfactory thing that Crocuses can do, as the leaves hereafter will burst and spread as if a bright green sheaf was suddenly unbound. My Hyacinths are growing on in the most stumpy and rooty fashion, much also to my approval; and some of the groups will soon be ready to be parted up with moss, an operation which needs to be performed with extremest care, so as to cover the roots without letting any scraps catch upon leaves and stems.

My planting, however, is by no means over yet. A great many bulbs have been put in this week, including a lot of Messrs. Cutbush's first-rate exhibition flowers, which I hear take all the prizes, and which will, I hope, do great things for me next spring, all the bulbs being of that weighty ivory-hard feel which promises so well for their vigorous growth and blossom. I am planting all my Hyacinths now, however, in pots. Water and sand are well for early flowers, but where we want to have first-rate blooms pots are the right things.

Here, however, I must correct myself. I mean no disparagement to baskets and dishes when they are still required, as very many ought to be for February and March. Above I was speaking strictly of the "exhibition Hyacinths," which, whether from Cutbush's, Barr & Suggden's, or Hooper's, the only three sets that I have been planting lately, seem to me this year in wonderfully fine condition. The groups, however, may still go on most flourishingly in blue Hyacinth-dishes (I believe these can be made by Millington of any size to order, at a very small expense). Plain glass milk-pans, soup-plates, and large saucers, zinc dishes also, or zinc trays, for sinking in Mignonette-boxes, or jardinières, are absolutely invaluable, and outside a window, especially if shaded by a frame of glass in wet or snowy weather, they would form, with some evergreens, a lovely little spring garden. This may be a useful hint to your last week's correspondent who wishes to have flowers showing from the inside of his window. They will also be lovely from the outside too, and if used by any one living in a town, what can be more pleasant than to give a glimpse of real bright spring flowers to those who see so few? Nothing so delights me as filling my garden in the early spring for the passers-by. I so like to see and hear a line of children jumping about and scrambling after the flowers!

These groups for dishes and window-bars, I may as well here remark, can now be obtained all assorted properly for immediate use. Messrs. Barr & Suggden some time ago wrote to me for data as to those which I had used myself, and as it was a thing I was most anxious to see accomplished, it is with very great pleasure that I now note the fact, as so many people, of course, do not know at first how to assort either colours, or height, or time of flowering, so as to make up a really pretty and suitable group for growing.

These groups next year will be, I hope, very much more extended; at present I do venture most strongly to recommend such as have been prepared.

They are all made up from whole groups, to which it is concluded nothing will be added; and in sending orders I believe it would only be necessary to mention the size of the box or dish to fill, the colours preferred, and the sort of flowers—that is, Hyacinths and Scillas, Tulips and Crocuses, or Scillas and Snowdrops, which alone are lovely.

I will now only add that in dishes where water only has been used, a little silver sand poured in among the bulbs through a long-eared funnel will keep them steady and upright when they grow up tall; and if Crocuses should be attacked with green fly, which mine have not at present been, a dusting with insect powder will speedily set them free.

When the flowers are in blossom, if the sunshine never falls upon them, they last immensely longer, and every fading flower must be always cut off at once—I mean a decaying flower. Quantities may flag with temporary over-heat or dryness, but they will all recover. Great care must be taken, however, not to break leaves or roots.—E. A. M.

DEATH OF PRINCE ALBERT.

WITH no ordinary sorrow do we record this event, which will be heard with deep regret by every true-hearted subject of our Sovereign, not only because of the grief and loss that can have no reparation to her, but because also of the high esteem in which His Royal Highness was held.

We are entitled to make this notice if for no other reason than that he was President of the Royal Horticultural Society, the members of which, in common with those of many other associations for the advancement of the arts and sciences, will long remember his energy, judgment, and urbanity.

His Royal Highness was in his forty-third year, being born in 1819, and dying at Windsor on the 14th instant.

ROYAL HORTICULTURAL SOCIETY.

DECEMBER 10TH.

FRUIT COMMITTEE.—Mr. Graham in the chair. At this Meeting prizes were offered for the best and second best dishes of Black and White Grapes; and for the best and second best three dishes of any variety of Apple and Pear respectively. In the Grape class Mr. William Thomson, gardener to His Grace the Duke of Buccleuch, Dalkeith Palace, exhibited a very large bunch of Calabrian Raisin in fine condition. The flavour of the fruit was rich and piquant, and it was awarded the first prize for White Grapes. Mr. Thomson also sent a bunch of Lady Downes' Seedling whereby to compare the keeping properties of Calabrian Raisin, and both appeared as if they would hang equally well. The Calabrian Raisin has always had the reputation of being an excellent keeper. A remarkable character in the Lady Downes' Seedling, exhibited by Mr. Thomson, was its possessing so marked a flavour of the Muscat. This was apparent to every Member of the Committee; and the question was suggested whether or not it had come from a Vine grafted on a Muscat, and thereby acquired that flavour. In this class Mr. Mackenzie, of Brighton, exhibited Marchioness of Hastings, which produces large bunches, and is a very inferior Grape in regard of quality. Mr. R. W. Craik, gardener to F. T. Rufford, Esq., Prescott House, Stourbridge, sent fine bunches of Black Morocco, and these took the first prize in the class of Black Grapes. He also exhibited a bunch of what was named Black Frontignan, but which was in reality the Black Morocco also. Mr. Graham, of Cranford, again exhibited bunches of his Cranford Muscat, a small highly flavoured Grape, which has the property of not cracking like the Chasselas Musqué. The bunches

had been cut some time, and the berries had become somewhat shrivelled and were very finely flavoured. These bunches had been ripened in a house without any fire heat.

In the competition for Apples the first prize was awarded to Mr. John Newton, gardener to G. J. Graham, Esq., East Lodge, Enfield Chase, for Cornish Gullidower, very full-flavoured and rich. Sam Young, a small, round, and flattened russet Apple, with very firm and tender flesh, very juicy and with a fine flavour. Ribston Pippin, very good. The second prize was awarded to Mr. Cunningham, gardener to the Bishop of London, Fulham Palace, for Blenheim Pippin, very good and well flavoured. King of the Pippins, also very good; and a variety of Russet called Sykehouse, but which was not so. It is a good Apple, but the sort could not be identified. Mr. R. W. Craik exhibited in this class also. The sorts were Blenheim Pippin, Wyken Pippin, and Cellini. These being grown in a more northern climate were yet immature, but were excellent examples of the various kinds.

Mr. John Hodge, Nurseryman, St. Austell, Cornwall, sent dishes of Tom Knight, Smith's Pippin, and a variety of table Apple unknown, but these were not equal in flavour to any of the others. Mr. Kinghorn, Nurseryman, Richmond, sent dishes of Adams' Pearmain and Rosemary Russet, both very beautiful examples of these excellent varieties. C. W. Strickland, Esq., Chairman of the Yorkshire Local Committee, sent specimens of Chapman's Ribston, a sort that was exhibited before the Committee last year, when it made a very favourable impression by the excellence of its quality; but this season it was very much inferior in flavour, and evidently had not acquired its true flavour. Mr. Strickland also sent a very large green Apple without a name, which was considered by the Committee as a very valuable kitchen Apple. Chas. C. Temple, Esq., High Ackworth, Pontefract, sent a very handsome large Apple of good quality, supposed to be a chance seedling. It has a tender flesh, crisp, briskly flavoured, and a fine aroma. The Committee requested that it might be sent again. R. T. Head, Esq., of Alplington Road, Exeter, sent specimens of a large seedling Apple of good quality, but it was not considered equal to many others already in cultivation.

The only exhibition in the Pear class was sent by Mr. D. Cunningham, gardener to the Bishop of London, Fulham Palace; but as no names were sent with the fruit they were disqualified. They were excellent specimens of the sorts exhibited, and consisted of Bauré Die, Bauré de Rance, and Winter Nelis. Mr. Cunningham also exhibited three varieties of Chestnuts grown in the grounds at Fulham Palace, which were distinguished by the names of resca, pumila, and media. The best was that named resca, the fruit being rounder and better filled than that of the others. He also exhibited a dish of the Dutch Medlar. Mr. Cunningham also sent two punnets of Mushrooms—one of the common garden Mushroom, and the other with a thinner cup and tough slender stalk, and the colour quite white. Mr. Cunningham's object in exhibiting these was to show that inferior and in some instances poisonous Fungus may be introduced in the soil used for covering the Mushroom-beds.

G. W. Wilson, Esq., of Gishurst Cottage, Weybridge Heath, exhibited fruit of Chaumontel ripened in an orchard-house. The fruit was covered with a fine, glowing, cinnamon-coloured russet, and was very handsome; but the flesh was coarse-grained and crisp, though with a high aroma and good flavour.

J. B. Haig, Esq., of Chapel Street, Pelgrave Square, exhibited the fruit of Bertholletia excelsa, the tree which produces the Brazil nuts. The fruit consists of a large wooden capsule filled with a great number of the triangular seeds, which lie one over the other, and are attached to a central placenta.

FLORAL COMMITTEE.—The dark days of December do not afford many subjects for consideration in the floral way; and consequently the Meeting, so far as new flowers were concerned, was well nigh a *dies non*. Other important matters were, however, discussed and arranged.

Messrs. Carstairs, of Edinburgh, again sent blooms of their white tree Carnation, the Bride, which promises to be a useful flower.

A rather pretty plant came from Mr. Potter, gardener to Mr. Colvin, Little Beelings, Woodbridge, Suffolk—a species of Parochetus, with a leaf very like an Oxalis, and with a light azure blue papilionaceous flower. It was not, however, in sufficiently good condition for an award, the flowers being nearly all over.

Messrs. T. G. Henderson & Co. sent a fine plant of *Inatophyllum Gardenianum*; and three varieties of *Epiphyllum truncatum*, grafted as half standards and forming pretty objects. Also *Crassula laeta*.

From Mr. Standish, of Bagshot, came one of the new Japanese *Chrysanthemums*—*laciniatum*, having the florets curiously divided and fringed, and likely to be of use in hybridising.

A pretty little plant of *Echiodendron Princess Royal* was exhibited, originally introduced by Mr. Veitch. Its very peculiar habit of blooming and the shape of its flowers, reminding one of some of the Trumpet Honeysuckles, make it interesting. One or two foliaged plants of no great merit were sent by Mr. Bull. And lastly, the most interesting plant exhibited, which came from Messrs. Veitch & Son—viz, a fine plant of *Angraecum sesquipedale*, a very fine Orchid from Madagascar, so often mentioned by the Rev. Wm. Ellis in his interesting accounts of that island, from whence we may now look forward under its new king for so much. The country will be opened to European enterprise and science; and doubtless our English cultivators will not be behindhand in sending there. For this a First-class Certificate was awarded.

PINE APPLE CULTURE.

(Continued from page 87.)

LIST OF VARIETIES—Continued.

The Black Prince.—Habit, tall-growing. Leaves, long and medium in width. Fruit, very large, pyramidal in form; dark orange-coloured when ripe. Flavour good. An excellent variety. Raised at Foxholes, the seat of J. Entwistle, Esq., near Rochdale, in Lancashire. Supposed to be a hybrid between the Ripley Queen and the Blood-red Pine. I have seen fruit of this very handsome Pine Apple 16 inches long, 6 inches diameter near the bottom, and weighing between 7 and 8 lbs. avoirdupois.

Smooth Cayenne.—Habit, tall-growing. Leaves, long and broad. Fruit, very large, rather globular in form; yellow when ripe. Flavour excellent. This fine variety was imported from Cayenne, as its name imports, many years ago, and is now cultivated in many places. The finest and largest number of it is grown, I believe, at Chatsworth. I once saw there a pit 100 feet long filled entirely with it all in fruit, some of which I judge would be less than 7 lbs. weight.

Prickly Cayenne.—In habit much similar to the smooth variety, but upon the whole it is an inferior variety.

White Providence.—Habit, tall and stout. Leaves, rather long, very broad, and covered with a white powder. Fruit, extra large, rather globular in form. Pips broad and flat. Colour dark yellow when ripe. Flavour medium. The fruit is very juicy, and the scent of the fruit is powerful. This variety is now well known, and highly and deservedly esteemed. With the exception of the Black Jamaica, its flavour is equal to any other when properly ripened. However, it is not considered a good sort for winter.

Trinidad.—Habit, tall-growing. Leaves, long and narrow. Fruit rather large, handsome in form, and well-flavoured, dark yellow when ripe. When this kind was first introduced from Trinidad, marvellous reports accompanied it. Amongst the rest it was mentioned that it would reach the extraordinary weight of 20 lbs. It has proved indeed, to be a fair variety, but, generally, I may say it has disappointed the cultivators.

Black Antigua.—Habit, tall growing. Leaves, very long and narrow. Fruit, medium-size, globular in form. Pips, large, broad, and flat. Colour, when ripe, dark yellow. Flesh nearly white. Flavour when just ripe most excellent, but it keeps badly. This good old kind has nearly gone out of cultivation, chiefly because of its straggling habit, and frequently coming up with the fruit diseased. Yet when it shows well and finishes well, few sorts can surpass it.

Enville.—Habit, rather tall, but compact in growth. Leaves, long and broad at the base, and covered partially with a white powder. Fruit, rather large, pyramidal in form, and bright yellow in colour. Flavour good in summer, but indifferent in winter. A very handsome variety raised from imported seeds at Enville Hall, the seat of the Earl of Stanford. This kind is harder than most others, and is more cultivated, perhaps, on that account.

Blood-red.—Habit, tall. Leaves, long, and rather broad,

shaded with purple in colour. Fruit, medium size, pyramidal in form, and dark blood-coloured. Flavour moderate. This variety is chiefly grown because of its singular colour, which pervades even the interior flesh. In all other points it is very inferior.

I might add several other varieties that were cultivated some fifty years ago. Such, for instance, as the Brown Antigua, the St. Vincent, the Sugarleaf, the Havannah, and others; but it would be superfluous, for they are all now obsolete—gone out of fashion and cultivation. The striped varieties are now cultivated as beautiful-foliaged plants for ornament only.

SOIL.

The Pine Apple will grow in most any kind of soil; but experience has proved that if the soil is too light the plants will run into fruit before they have attained their full growth, and hence the fruit will be small, and not so well flavoured; whilst on the other hand, if a rich, strong, heavy soil is used, the plants will continue growing for years without fruiting. It is evident, then, that a soil of medium quality is the kind that should be made use of. The principal part of the soil I have used is turf from a sheep-pasture pared off 3 inches thick, and laid up in a long ridge-like heap not more than 2 feet or 3 feet high, and 1 foot or 5 feet broad. This heap should be turned over four or five times during the year. This turning over destroys weeds, and exposes every part of the soil to the ameliorating influences of the atmosphere. The best season for getting this turf is summer, for then it is dry, light, and easier to cart home.

The next article I use is leaf-mould. The leaves to make it of should be collected in the autumn soon after they have fallen. I prefer Oak or Beech leaves, because they are longer in decaying, and consequently give out nutriment longer than more sappy leaves. Collect them together and lay them in a heap not too thick, and throw over them a thin layer of light soil to prevent them being blown about. At the beginning of the year turn over the heap, and if any part of it is dry, wet that part with rain or soft water. Repeat the turning every three months, and by the end of the year it will be fit for use.

The third ingredient I use is dung. There are several kinds, such as deer's, sheep's, horse, cows', poultry, and even swine's dung, all of which have been recommended by different writers. For my part, I was always satisfied with any one of them that I could get: hence horse dung that I had used for Cucumber and Melon-beds being handy and half ready for the purpose satisfied me well. The fact is, any dung is enriching, though some are more so than others: hence if deer or sheep's dung could be obtained in sufficient quantities, I should prefer either of them to horbed dung, though the latter is good enough, and will grow the Pine Apple excellently.

In addition to these three principal articles, I recommend the addition of a small quantity of quicklime and sharp sand, or if that cannot be had, then use some other kind of sharp sand. I have used charcoal broken small with advantage.

The various articles having been collected and duly manipulated, I then mix them together at the times they are wanted, in the following proportions:—

Six barrowloads of decayed turf.	One peck of sharp sand, the dust to be blown out of last mould.
One barrowload of dung.	One peck of quicklime.
One peck of charcoal broken small.	

Mix these all thoroughly together in a rather dry state, and lay the compost in a warm shed to become aired. Do not sift the compost at all excepting for small suckers and crowns, and even for them use a wide-meshed sieve. If used too fine the compost will run together and be too compact for the fine roots to penetrate.

There is yet another article that is indispensable to successful culture of the Pine Apple, and that is the material for drainage.

Some authors recommend rough sand for this purpose; but I prefer the old-fashioned drainage—broken pots. These should be in three sizes, the first large enough to cover the holes at the bottom of the pots (though if oyster-shells can be had they answer for that purpose still better, for they afford nutriment to the roots). The second size should be as large as a penny-piece; and the third about the size of horse beans. These should all be ready in sufficient quantities before the potting season comes on. In preparing them, if the broken pots are dirty, I should throw the corks into a tub of water and scrub them well with a rough broom, and then lay them somewhere to dry.

(To be continued.) T. ASPLEY.

AN EASY MODE OF REDUCING BONES TO POWDER.

EVERY one wishing to employ bones for manure must have been more or less troubled in reducing them to a state of powder, or fragments, suitable for the purpose. Even treating them with sulphuric acid so as to convert them into superphosphate of lime, is an uncertain and awkward process for those who are not provided with appropriate utensils. A much more simple, and one devoid of hazard, has been suggested by an American gentleman, as stated in the following extract from the *Boston Cultivator* :—

James S. Grenell, Esq., of Greenfield, practises dissolving bones by a method which seems worthy of notice from its simplicity and convenience. Casks having each but one head are provided; a layer of bones 4 inches or 7 inches thick placed on the bottom; then strong, unbleached wood ashes are spread over the bones to the thickness of 2 inches or more. The casks are filled in this way, taking care to have a pretty good thickness of ashes at the top to prevent the exhalation of ammonia. The process of thus packing the bones goes on through the season, as ashes accumulate in the house, and they remain in the casks till spring, when the casks are emptied, and the bones are found to be generally well pulverized, or so soft that they can easily be broken as fine as desired. The mixed bones and ashes are excellent manure for most crops, and especially for fruit crops.*

The power of the wood-ashes to reduce the bones to a powder must be owing to the caustic potash which they contain: therefore, as it would be difficult in this coal-consuming country to obtain wood-ashes in sufficient abundance, the cultivator desiring to pulverise bones for manure might sprinkle them over with potash in powder; or mix some potash with charred vegetable refuse, and pack this mixture in layers, alternating with layers of bones, as directed by Mr. Grenell.

We are quite aware that by thus using potash the phosphate of lime in the bones is converted into phosphate of potash; but we are also aware that this salt in some soils is more useful as a manure than phosphate of lime.

Professor Johnston observes of the phosphates of potash that they are "perhaps very generally present in the soil in minute quantities; and there is every reason to believe that could they be applied to the land in a sufficiently economical form, they would, in many cases, act in a most favourable way upon vegetation. They are contained in the urine of carnivorous animals, and in many other animal manures; and to their presence a portion of the efficacy of these manures is to be ascribed."—(*Lectures on Agric. Chemistry.*)

SHORTT'S PLAN FOR THE PRESERVATION OF POTATOES FROM THE DISEASE.

This plan of laying down and moulding the stems of Potatoes all but a few inches of the tops is as old as the hills; for the washing of the mud from the sides of their native hills, by storms and tempests, did the same thing from the beginning; and under cultivation the plan was adopted, practised, published, criticised, and commented upon many years before the first appearance of the Potato disease, in the volumes of "The Gardener's Magazine," from 1830 to 1834, but I forget the exact time.—D. BEATON.

[Mr. Hayward suggests the plan in "The Gardener's Magazine" for 1833, page 323.—Eds.]

I TAKE UP THE JOURNAL OF HORTICULTURE this morning (Thursday), and open upon Mr. Fox's letter. I find that he charges me with, 1st, "rashly and publicly condemning" Mr. Shortt's plan before fully comprehending the directions; to which I reply that his penetration is very obtuse indeed, else he would have perceived that my letter is only a simple record of an experiment, conducted and finally carried out with the strictest impartiality. He charges me with, 2ndly, total misapprehension of the instructions which he describes as so "plainly and lucidly expressed." My reply to this is, Take another look at the instructions, Mr. Fox, because, what does this mean—"If I understand it aright the principle is, &c.?" Now, this admission of a doubt as to his comprehension of the principle, weakens, nay, stultifies his charge of my misapprehension.

I find that Mr. Mildford admits that there has been some disease this year, even on the fine crop at Coover, under the system carried out by Mr. Shortt himself. Let them give us the weight, per acre, of their own crop—not hearsay reports as

to the "thorough and undoubted success" of the system in Norfolk. This is only what is just to all of us, and would carry conviction with greater force than baseless charges of misapprehension.

I can well understand the neighbourly feeling that has prompted Mr. Fox to break a lance in defence of his friend; but, as he has not personally tried the experiment, he cannot be admitted as a champion. Let me give him "A RENFREW-SHIRE BEE-KEEPER'S" quotation in this week's Journal:—

"Facts are chieftains that win a ding,
And darna be disputit."

As Mr. Fox has exonerated my employer from misapprehension, I beg that his name may be no more mentioned in this matter. I prefer fighting my own quarrels with my own weapons. The injustice of Mr. Fox's charge against Mr. Sanday is so palpable, that I bitterly regret ever having mentioned his name.—N. H. POWNALL, *Holmes Pierrepont.*

TREATMENT OF FROSTED PLANTS.

ON perusal of your Number of the 26th November, I was much amused at the plain avowal of my neighbour "N. H. P." as to his troubles of the night of the 15th inst. It is an old and a worthy saying, that simple confession is good for the soul; but in this instance there was no cause for so full a confession of his misfortunes, since so many, especially of the fairer portion of your readers, will be ready to exclaim "N. H. P." must be little versed in the weather to be totally unprepared for so severe a frost as that of the 15th inst.—viz., 12°. It was a favourite saying of a gentleman with whom I lived in Cambridge, "A gardener should from the 1st of November to the 1st of May sleep with one eye open." Now, this does not appear to have been the case with "N. H. P." happy man!

"His slumbers deep, his cares but few,
He slept all night, no changes knew."

I can readily imagine his appearance on first halting that chilly morn. No time for reflection or thought, prompt action was the order of the day; and kindly did Fortune smile upon him, in that before his fire had become brisk enough to raise the temperature to that climax of गरिमा's 32°, bright Phoebus did not dart forth his beams to dispel the thick coating of frost on the glass, in which case he might not have come off soot free.

I do not condemn the practice of raising the temperature by fire heat, because all must be aware the longer plants are subjected to a temperature so low, the more likely are they to be injured; with me it has always been under-wood prevention is better than cure. It may be that in the few miles separating "N. H. P." and myself there may have been great difference in the temperature on that night; at 10 p.m. here it indicated but 33°. Not safe, said I, so I had the fires lighted, and before 11 I could comfortably turn in to undisturbed repose, safe in having taken the view of matters, nationally ours, that being well fortified, it is far easier to keep an enemy out of the camp than to oust him when there.

I need not trespass further on your pages than to illustrate the ill effects at times arising from such measures as those of "N. H. P." Some years since, I cannot tax my memory with the exact date, a friend living close by me was fixed in a like dilemma, and very naturally flew to fires as his remedy. In his anxiety he asked my advice on the subject, when I suggested the propriety of raising to 32°, and immediately applying a copious syringing with cold water. This he could not see to be right; but after arguing the point some what further, he agreed to test it by syringing one house and leaving the remainder to thaw by action of fire. Unfortunately for his ancient notions, as frequently is the case after frosty nights, then occurred one of the bright mornings when the sun breaks forth in all its splendour. It needed no nicety of eye to discriminate between the two methods; the superiority of the cold bath to the chilled and frozen pots soon became apparent in the glossy-green leaves, against their dejected-looking neighbours, closely resembling in colour our poor Dahlias under similar circumstances. I do not wish for a moment to condemn or to impute mismanagement to my friend, human nature is prone to err, I would only suggest that should he again have the misfortune to be placed in the same fix, to try the invigorating effects of a cold bath for his invalids, and to hope these few lines may be of service in extricating some one of my brethren from a like dilemma.—O. B.

[We inserted the communication without any comment in the

expectation that it would elicit some observations from other correspondents. "O. B." is quite right. If plants are frosted shade them from the light, let the temperature rise, if possible without fire heat, to 32°; then syringe with water not higher in temperature than 35°, and continue shading the plants for an hour or two afterwards, or all day if the sun shines brightly.—Eps. J. or H.]

POURING WATER ON FLUES TO REDUCE THE TEMPERATURE.

WORLD the Editors inform "E. D." whether any harm arises to her plants at this season by pouring water over the flues when she finds the temperature of her house many degrees warmer than is required for her plants? An answer will set at rest a dispute between a gardener and his mistress, and greatly oblige an old subscriber.

[We have no love to be arbitrators in any case, and least of all when one side only is presented to us. However, we may say, in general, that unless in extremely strong flues, and extremely high tropical heat required, we object to wetting flues at all; but would obtain atmospheric moisture by means of evaporating-basins. So much for general cases. In houses moderately heated, we would object to wetting a flue at all at this season. When too much heated we would object still further, as a burning vapour would be thrown among the plants, worse even than air too much heated. We should just put the fire out, and give air freely if the weather was mild, and if cold and frosty give air at the top of the house only, and neutralise the dry atmosphere by sprinkling the paths and stages. If such extra dryness of the atmosphere rendered such sprinkling necessary. We would do this, even if there were no danger of hurting the flue, cracking it, and letting out effluvia in which plants could not live and thrive. Many a good flue has thus been injured, and many a crop been spoiled—that is, when the flue was very hot and water was used for cooling it. We would never throw water on them at all.]

WRITING ON ZINC LABELS.

I CAN give you a better (because a more expeditious and an equally efficacious) method of cleaning zinc labels than that named at page 163.

Nitric acid one part, water three parts. Wash the label with a roll of linen (taking care not to touch the fingers with the mixture), and when clean place immediately into cold water. Wipe carefully dry.

A far better ink (because so much cleaner to use) is to be bought at any of the seed-shops for 6d. a-bottle. To be used with a quill pen.—H. R.

FIG TREE PRUNING.

Of all the fruits which we cultivate in Britain, the Fig tree seems to be generally least understood. This is probably owing to the peculiarity of its mode of bearing, and the abortive luxuriance consequent upon the too free use of the knife, to which it is frequently subjected in order to bring it into regular shapes. No tree requires a smaller degree of pruning; and the old adage that "a pruned Fig tree never bears" is literally a truism.

The Fig tree is distinguished by this peculiarity—that in the course of one season it produces, upon two distinct sets of shoots, two crops of fruit. The Figs which appear when the first flow of sap takes place are those which alone ripen (upon a wall in this country) generally in September; those which are produced afterwards do not come to maturity in our sunless climate. But under glass, assisted by artificial heat, they succeed perfectly. It must, therefore, be the object in managing the Fig tree, as to pruning, to secure the greatest possible amount of moderately strong, short-jointed, and well-ripened wood, and to remove by degrees from the tree those shoots which have become old and naked. This must never be carried to an excess of severity, but must be a work of watchful and cautious progression. Root-pruning will always be found a useful auxiliary, and confining the roots within a limited space of soil is always beneficial.

It is customary to train the Fig in the fan-shape; but this is

not the form best suited to induce productiveness, unless modified by recurring the points of the branches. It is but too common to see Fig trees mere aggregations of suckers; the branches emanating from the collar of the plant at the ground, and not being confined, as in other trees, to a single stem. The great objection to the fan-shaped training for the Fig is the excessive luxuriance which those shoots which approach nearest to a vertical position acquire; and the consequent unproductiveness of that most valuable part of the area upon which fruit trees are trained—namely, the top of the wall.

We have observed that in the open air, in this country, only one crop of fruit ripens, while under glass we have the power of bringing to maturity the second crop, which always ripens in warmer latitudes. It is, therefore, obvious that, as the results to be aimed at are different, so must our treatment vary. For a crop of Figs upon the open wall, then, our object must be, as far as art is available, to increase the number of embryo Figs which are developed from last year's branches with the first flow of the sap. In order to effect this the recommendation of Wickham is good, which we have confirmed in our own practice. It is, to "rub off, as soon as they can be discerned by the naked eye, all the Figs which are produced after midsummer on the same year's shoots." These Figs Mr. Wickham calls (not inaptly) "sterilising incumbrances," and the effect of removing them is, that at the base of each fruit so removed another embryo is formed, which will produce a fruit that will ripen in the following autumn.

The figure represents a shoot of last year. The first Figs were produced on wood of the previous year (which is not shown). The first growth, previous to midsummer, extends up to A; at the joints B B B a second crop was formed, which was removed, and other embryos are now formed, b b b [not well represented]. From A to C is the second shoot, showing also Figs for the first crop of next season. Thus by this mode we succeed in getting a show of fruit which will come to perfection along the whole growth of last year by merely removing that which in our climate no skill could have brought to maturity.

Mr. Knight found that whenever a branch was extending with too much luxuriance, pressing it between the finger and thumb till its soft cellular substance was found to yield (not letting the nail come in contact with the bark), had the effect of repulsing the sap, and in consequence a fruit was formed and ripened at the base of each leaf. These Figs were formed upon our shoot (see figure), and with sufficient heat would have ripened, but they were taken off, as shown on the shoot at B B B. The reader will probably understand from this the application of the management under glass and externally.

It now remains to say a few words upon the training and formation of the tree. Horizontal training answers well for the Fig; and Mr. Knight has recommended training them with a tall single stem and radiating branches from the top of it, in a steeple form. We think this is open to the same objection as fan-training—namely, the superior vigour of the most vertical branches, as compared with the depressed ones. We also venture to opine that training up a single tall stem with two horizontal branches at the top, and

then training down perpendicularly would be preferable, as calculated to balance the tree better. It is quite true that we seldom see Figs trained otherwise than in the fan mode, and that such trees, when the points of the branches are removed, and they are otherwise well managed, frequently produce fine crops; but such are exceptions to the general rule. In forming a horizontally-trained tree it must be headed down within 18 inches of the ground to three buds, two of which must be trained horizontally right and left, and the centre upright, to be again headed back to form future tiers of branches. Thus it will appear that the use of the knife in managing the Fig tree should be very occasional; the cuts may be "few and far between." A vigilant eye and the finger and thumb may do nearly all the pruning requisite.

Fig trees in pots may be thus managed without any use of the knife; frequent stopping, pendulous training, and a rich soil will do all they can be desired to do, with root-pruning, which is of much consequence to their success. Late in the autumn they may be annually turned out of their pots, and the roots pared (to the thickness of an inch) all round with a sharp knife, and then repotted in strong rich soil. This plan was long practised at the late Lord Harewood's seat in Yorkshire with most successful results.

My friend Mr. Rivers, of Sawbridgeworth, who is one of the most able and intelligent of cultivators, has succeeded perfectly well with Figs in pots, by allowing them to root during their growth into the open soil and stimulating them with a rich surface dressing. When the fruit is ripened the roots are cut off and their surface dressing cleared away. For successive crops the trees undergo again and again the same process.

Standard Figs are now seldom met with, unless in some very favoured locality. The finest fruit we have seen lately was during the past autumn on some trees at Osborne House, the seat of Her Majesty. They only require a dry bottom and a genial climate. In such places the pruner may consider his "occupation gone," unless the branches (very occasionally) become too crowded.—H. BAILEY, *Gardener, Nuneham.*

SPERGULA PILIFERA A SUCCESS.

SCARCELY anything in the horticultural world has elicited so many and so diverse opinions as this little plant. Its distributor, Mr. Summers (Spergula Summers, as "NICKERBOR" facetiously styles him) believes it will effect a revolution in flower gardening, as a substitute for grass lawns. The very numerous gardeners who have succeeded with it are of well nigh the same opinion; while its detractors (and I am sorry to confess they are not few) are loud and positive in their condemnation of the "little humbug," as they call it.

To test its merits. In the first week in October, 1860, we had near upon 2 cwt. from the Crystal Palace Nursery. I had a notion that for one place in our garden it would answer admirably. The sort of place most readers of THE JOURNAL OF HORTICULTURE will understand, when I call to their remembrance the eloquent description given of it by Mr. Beaton, when describing the Crystal Palace Gardens at the visit of the Emperor and Empress of the French. See THE COTTAGE GARDENER, Vol. XIV., pages 67 and 68.

In the year that this was written our flower garden underwent reformation, and one of Mr. Beaton's ring-beds was introduced into the design; only ours is a diamond instead of a circle, a vase stands in the centre. I endorse all that Mr. Beaton says respecting them, both aesthetically and economically, with one exception—the centre of grass inside the ring. Mowing is out of the question, a boy and shears have to keep the grass under during the summer. This was a great draw on our labour, and I determined to try *Spergula pilifera*.

In Mr. Fish's criticism of the Crystal Palace Gardens, Vol. XVII., page 42, he takes strong objections to these beds of Mr. Beaton's for the very same reason that we wanted a substitute for ours. I am thankful to say *Spergula* is that substitute, much more effective as a green floor, and it needs no attention, except you may call that attention, when, on the recommendation of Mr. Summers to roll it, we (my garden had and I) consolidated it by a sort of North American Indian war dance, an eccentric variety of movements that would have irritated the nerves of a musician outrageously. We contrived to do it when no one was near.

To those gardeners who want their Grasses as soon as the

Vine is planted, *Spergula* will never be a favourite. A piece of ground planted with *Spergula* (especially if from motives of economy you make the spaces between rather wide) does not look "eyeable," as a friend of ours says. But, patience, my impetuous brother; do not plant too wide, and do not expect great results the first year, and I think you will be satisfied in the end.

It is amusing to hear the critiques of visitors who have seen our *Spergula*. "In the winter and spring, 'I don't think a deal of *Spergula*.'"—A smile of pity for our credulity. In summer, through negligence in watering, it looked a bit yellow.—"Hm, *Spergula* came out with a great name, but I should think you're heartily tired of it."—This, with a look of superior wisdom, and I-told-you-how-it-would-be sort of air. Autumn, "What a beautiful green *Spergula* is! such a contrast to the yellow colour of the grass! How do you like it?" Well, we answer, so much so, that we are going to plant as much of our grass plot as we have *Spergula* to do it. "Ah, I rather like it."

In any garden, where on the sloping banks the grass grows coarse and patchy, or as centres for ring-beds, or as divisions between beds in a small geometrical arrangement, or as a substitute for grass in the little front gardens attached to houses at the outskirts of towns where a bit of green is so striven for, *Spergula* is the thing. "The right thing in the right place."

Our mode of operation is: Dig the ground, level it, tread it level again, break the *Spergula* turf into pieces about the size of your thumb (mine from much use is more broad than elegant) and press into the soil, make the distance between the same size as the bits of *Spergula*, throw on some sifted soil, leaf mould, or refuse potting-bench stuff, flatten with the back of a spade, and the job is done.

This applies only to *pilifera*, *saginoides* I have not tried. Ours is light soil, and our instructions say *saginoides* is better adapted to light soils than *pilifera*, *pilifera* being more at home on the stiff clays.—WAIT.

MANAGEMENT OF WINDOW PLANTS IN WINTER AND SPRING.

I HAVE a few Geraniums, Fuchsias, Calceolarias, &c., which, for want of a better place, I grow in my window, both inside and out. For the last few years they have bloomed so late that the frost has destroyed the bloom prematurely. Will you be so kind as to tell me whether it is my fault or not? I serve them as follows:—In autumn I take them out of the pots, prune root and stems, and return them to the pots again afterwards. I put them in a dark corner of the room. In spring I again repot them, and water them. If this is not the way will you tell me the right, and likewise the proper compost I ought to use?—A CONSTANT SUBSCRIBER.

[We would give more definite advice did we know what kinds of Geraniums, Calceolarias, &c., you do grow. In the meantime we can have no hesitation in advising you to obtain "Window Gardening for the Man," which by post will be 10d., and then we have as little hesitation in stating that your practice is just the best you could take to obtain late flowers, and but few of them.]

In the first place it is not a good plan to cut the stems of a plant and to prune the roots and repot at the same time. It is best, when pruning is needed, to prune first, and under your circumstances when the buds have broken, either repot into smaller pots, or allow the plants to remain in the pots, and either pot or top-dress in the spring. In either case plants might be a little shaded after potting; but keeping plants that are growing in a dark corner of the room in autumn and winter, and giving them more pot room in spring, must give such an impetus to mere extension, that we do not wonder such plants bloom late. All plants growing should have as much light as possible in winter.

To be more precise, we will notice the three kinds of plants more particularly. First, then, with respect to Scarlet Geraniums. We have some four plants of Tom Thumb that are the admiration of every one who sees them, as the centres of beds in summer. Well, these plants have been in the same pots, summer and winter, for more than a dozen years. They are set anywhere free from frost in winter, and sometimes by Christ-mas they have not a single leaf on them larger than a fourpenny-bit. At this time they are kept rather dry. No pruning to speak of is given them, but the shortening of any shoot stronger than the rest, and nipping off any little bit that is showing

signs of weakness or decay. About March or April a little surface soil is picked off carefully, and a rich top-dressing is given. The plants are put out of doors under protection in April, and generally from June to the end of October they are a mass of bloom, for in dry seasons the plunged pots can be wet red, and in wet, dull seasons the rain is thrown past the roots by the width of the head and foliage. Were it not for the expense and the housing, such plants would present a far more magnificent display than those either young or old turned out in the open ground. For fine display from *Scarlets*, then we advise adopting this plan, which Mr. Beaton calls the Harry Moore system.

But with florist and fancy *Pelargoniums*, especially the former, it is necessary to prune after the wood is well hardened after flowering. The plants should stand in the sun afterwards until the fresh shoots are from half an inch to an inch long; then if the pots are rather small the surface soil should be removed and fresh surfacing given, and the plants obtain all the light possible. If the pots are large for the plants, then after the buds are broken you may carefully shake the soil away, prune the roots a little if very straggling, and repot in much poorer soil, and smaller pots; and keep shaded from bright sun for a week, and then gradually inure them to all the sun-lime they can get. If you want early blooming these should not be shifted again at all; but, if you want good plants as well as bloom, give them one size of pot larger in March or April, and pot hard and firm all the time, never moving the plants from the light. The dark corner will be ruinous to them. They will stand no darkness, and no rough treatment, like a *Scarlet Geranium* deprived of most of its leaves.

Then whether the *Calceolarias* be herbaceous or shrubby, if in pots, we would prefer pruning a little in autumn, keeping them in the same pots all the winter, and repotting into larger pots in March or the beginning of April. These, too, must have light in winter to bloom early. When they are kept in a darkish place they must also be cool; hence we last season had *Calceolarias* by the thousands shut up from all light for six weeks; but then it was just like one night to them, as during all that time the temperature in which they were was not more than a few degrees above the freezing-point. Had such plants been kept in a room, and in a dark corner of it, and the heat of that room ranging from 40° to 60°, then we should have expected the shoots to be such poor wire-drawn wren affairs that the bloom could only be expected to come when other people's plants were nearly over as to blooming.

Exception as to potting must be taken in the case of young herbaceous plants raised from seed in August; they, too, must have all the light possible, and may need repotting at Christmas, and again the beginning of March.

Fuchsias established in pots, and the *Scarlet Geraniums* ditto, are the only things you mention that would do in a cool shady corner of the room in winter; but though the *Fuchsias* may be partly pruned in, they should stand in the pots in which they grew all the winter, and be fresh potted, and brought to the light as the buds break in spring. Where there are no means of giving strong heat to young plants, these old plants so managed, are the best of all for giving abundance of early bloom to amateurs and window gardeners. The keeping and management of such *Fuchsias* has received great attention in late Numbers.—R. FISH.]

CULTURE OF PRIMULA FARINOSA.

I AM well pleased to find that the number of those who cultivate our native plants is on the increase, and that your correspondent "W." is trying to grow *Primula farinosa*, with which, I have no doubt, your correspondent will be successful. A friend of mine, who is a cultivator of many of our British plants, is very successful with it. He grows his plants in pots, in a cold frame, without any protection except in frosty weather, when the sashes are put on. They seldom fail to flower well and are very healthy. His old plants were collected in Craven, in the neighbourhood of Malpas, and are grown in the limestone soil of that romantic district. During summer the plants are weeded together without water; at other times they get a soaking during wet weather. When in flower they are shaded for two or three hours every day during intense sunshine, which causes them to continue longer in blossom and the colours are richer. Your correspondent "W." ought to grow plants with

white and others with deep crimson flowers, and save seed from them; by this means a great variety may be obtained.

There is a pink or red variety of *Achillea millefolium* (Yarrow or Milfoil) that is sometimes met with in gardens. I do not mean the red variety that is often found growing wild on the banks of our Yorkshire river Ouse; but a much taller variety growing upwards of 3 feet high, with large bunches of flowers, which strike the eye at a long distance. I have only seen this variety once, some time since. Can any reader of THE JOURNAL OF HORTICULTURE tell me the name of any nurseryman that has it for sale, or where it may be got?—RUSTIC ROBIN.

GENOTHERA MACROCARPA AND GAZANIA SPLENDENS AS BEDDING PLANTS.

I WOULD, with the assistance of the gentle readers of THE JOURNAL OF HORTICULTURE, devise a new bed upon this very principle. I would endeavour, with the assistance of the same, to replace an old, a general favourite—a very lady's favourite, in its former place upon many of our lawns, from which it has been taken with the wish for a better, a more pleasing substitute. A wish which, notwithstanding oft-expressed desires to have it replaced, has never been realised. I allude to the old favourite evening *Primrose* (*Genothera macrocarpa*). And its companion—the plant which is to be in such close companionship in this romantic one, which, poetically, courts the shades of evening to exhibit its lovely flowers to admiration—is a plant, a singularly beautiful flower, the properties of which I would endeavour to vindicate from the many unfair aspersions. I would form a bed by a judicious mixture of the above with *Gazania splendens*. Refute the very idea of such a bed—say it will not suit a gay parterre. Questionable if it does not prove as gay as many favourites there already; but its real place is the one or two secluded beds in the little nook or labyrinth called "my lady's own," for which nothing can be more applicable. What two in the whole list of bedding plants so striking when the *Gazania* is closed for the night? Then will the lovely *Primrose* expand to watch beside its cavalier-like companion until it awakes to greet it in the morn!

It is to be regretted that the *Genothera* cannot be more easily transplanted, as by the removal of old plants they generally become lost. A stock of the same can be kept up by means of propagation, &c.; and I think it possible, that if it were moved at some not at present well-known season, it could be accomplished with a greater chance of success, possibly just as it begins moving in the spring, like our old favourite border *Lily*, than which no time is better to remove the bulbs than immediately succeeding the first show of growth in the autumn. It is worth a trial in the spring—say April.

It is with no little pleasure I see a proof of the revival of interest in florists' flowers, more especially herbaceous plants; and I am very pleased to see THE JOURNAL OF HORTICULTURE take the lead in this respect. There are few of its readers, doubtless, who have not some happy idea of an old plant or two of this division impressed in memory, with which they would not part for all the bedding-out beds in Britain.

One of my own happiest marks in memory is the time spent in a superior herbaceous ground. I allude to the one planned and planted by Miller & Sweet, at Clifton, near Bristol, in possession of Garroway & Co. at present. Here each variety is kept studiously named, and there are very few weeks in the year without some little favourite taking its opportunity of greeting its seasonal visitors. Here, also, are some of the best-in-effect rustic-stone archways, rockeries, &c. They lose nothing in value with comparison with modern ferneries. Indeed, I question with all the rage for ferneries any do really beat these.

To return to our old fancies. What flower grown is at once more singular, more beautiful, I might almost say more gorgeous than our own *Lady's Slipper*, *Cypripedium calceolus*? and yet what flower is really less known that has any pretension to a place in a nurseryman's catalogue? It is really a deserving plant, undeservedly kept in the background. Here, also, are seen the huge *Thistle*, the emblem of the energetic Scot, known to few (save as seen in our national coat of arms), on this side of the border, and the pretty little *Phlox frondosa*, the queen of its class when grown to perfection. Here you are also forcibly reminded of the straits our forefathers must have been in for names wherewith to christen the many floral beauties. In close companionship you find the *Old Man's-beard*, the *Goat's-beard*, and the *Lamb's-beard*. This latter, though singular in name, is

rather a showy plant. A good belt of it would look well in any make-up shrubbery-border or otherwise.

A few words in conclusion in vindication of *Gazania splendens*. Is the real habit of the plant properly known? The majority write to say how bad it turned out at a certain place last summer, or the summer before. Indeed, I visited gardens myself where it met me as the most pitiful object, and simply because it was really not properly understood. Of all plants I know there are none that suffer so much, and at the same time show it so little. I believe the *Gazania* would live and look well whilst the veriest mite of sap (a white fluid which it contains in great quantity when healthy), remained in it. Then it would wither and show its sufferings, and then, perhaps, it would receive a pot of water. It would revive and, from appearance, thrive well, whereas it was suffering more than any other bedding plant in the garden. The *Gazania* is, so to term it, a very glutinous plant. It requires a thorough good border to grow and flower it properly; and unless it is growing in a healthy state, the flowers are not so large nor so many, and they open later in the day to close earlier. I have no faith in starving a plant of this sort with the object of a greater show of flower, for immediately you begin to starve it it falls back upon its sap required for active growth. The flowers then suffer; you retard and diminish the flowers you wish to forward, and receive greater powers of expansion. This is the whole secret of its doing in certain places so badly.—W. EARLEY, *Gardener, Digswell House, Welwyn.*

FERTILISING MANGLES' SILVER BEDDING GERANIUM.

CROSS-BREEDING AND HYBRIDISING.

IF Mr. Weston notices Mr. Smith's, of York, interesting communication, would he have the kindness to state whether Mangles' silver bedding Geranium can be fertilised by its own pollen and produce seed? and whether its pollen will fertilise other kinds of Geraniums?

[Mr. Smith's is indeed the most interesting communication we have had this season on cross-breeding, after the account of the influence of the shorter stamens of some genera. It will, no doubt, open a field for some of the cross-breeders; but I have stated in almost all our recent volumes that Mangles' Variegated Geranium does not produce pollen. It has not been known to cross with any other kind till the instance just recorded.

The natural species from which Mangles' is a sport, however, is the most inveterate seeder in the family, but it would not breed with others in the usual way. This is a good opportunity of explaining the difference which practical writers should observe between hybridising and cross-breeding. A seedling between Tom Thumb and Flower of the Day would only be a cross-bred plant, not a hybrid; but if the green parent of Mangles' Variegated Geranium would cross with Tom Thumb or with any other bedding Geranium the seedlings would be hybrids, and most of them would probably bear the character of hybrids—that is, be intermediate between the two parents, the two being distinct kinds or species. Again, if any of the Ivy-leaf kinds of Geraniums would cross with any of the other bedders, the seedlings would also be hybrids; but seedlings of crossed Ivy-leaf among themselves would only be cross-bred plants.

We are not aware of any hybrid Geranium being now in cultivation. They are all cross-bred plants, the offspring of one original kind; and so are the Verbenas, Calceolarias, Tropæolums, and most others of our common plants—hardly a hybrid among them all; and a fourth part of their number is not even cross-bred, but variations from one parent, as is the case lately supposed to uphold the doctrine of superfecundation.

Practically the difference between hybridising and cross-breeding is very great indeed. Ten seedlings from a true hybrid origin would give the hybridiser ten chances of an intermediate offspring between two distinct kinds of plants—as, for instance, between a Pontic Rhododendron and an Azalea; while ten seedlings from kinds of plants which are merely cross-bred among themselves would hardly give one chance of a true cross between the parents. The parents of all our bedding Geraniums, Verbenas, Petunias, Tropæolums, and of most of our bedding Calceolarias, have lost their fixed characters as distinct kinds or true species. They are broken down, as cross-breeders term it, and not one of them comes now true from seeds by its own pollen. Then the mere act of applying the pollen of any one kind of them on another and will not change their nature and

give an intermediate offspring. Their own unfixedness of character is necessarily seen in all their seedlings—that is to say, cross-bred plants exhibit characters which were never seen in either of their parents; in fact, they sport just as much when they are crossed as when they are not, so that crossing them has only one-half, if even so much, of the merits of their respective qualities: hence the origin of the reality of the mistakes about superfecundation.—D. BEATON.]

THE FARMER AND GARDENER COMBINED.

I HAVE inferred, from the generally excellent remarks of "THE DOCTOR'S BOY" on the combination of the farmer and gardener in such places as he describes, that the manager will have a few assistants; and I beg to ask, Could the person whom his "rating" improved find no more judicious employment for his time than milking the cows and feeding the pigs? I think it will be admitted that the gardener referred to would be the better by understanding the advantages of the subdivision of labour, and being taught to produce a better result by looking after the more important parts of his joint charge. He surely would be able to instruct an assistant to attend to the swine, &c.

As a young gardener, I will venture to say on the part of my fellows in the nurseries, or at least the intelligent and worthy portion of them, that if no better position is offered them to "stand in" than this trough and milk-stool business they are likely to remain in the nurseries, or try some other market.

But the combined management of the farm and garden can be conducted efficiently by the gardener without such attention from his own hands. Most of the places in Ireland (nearly all the smaller ones) are so managed, including those described by Mr. Fish and many more good ones, which I hope he will describe. I was not before aware that gardeners thought it degrading to accept such a situation; on the contrary, I believed it to be more respectable and in every way beneficial to them to have the management of the whole place in which they might be employed.—WILLIAM ROBINSON.

VARIATION IN THE LEAVES OF PLANTS.

I HAVE been considerably interested in several letters which have recently appeared in your columns relative to this subject. Some of your correspondents contending that variegation is synonymous with disease, and others inclined to think it entirely distinct from it.

In a former communication to you on this subject I admitted that variegation was invariably accompanied with a diminution of vigour, or at least carried with it a dwarfing influence; and most of your correspondents on the subject have, I think, admitted this statement to be correct. Still this admission does not in the least favour the idea that variegated or dwarf subjects must necessarily be diseased; on the contrary, I can perceive nothing to prevent a dwarf from being equally healthy and as tenacious of life as a giant, and I feel inclined to repudiate the term "disease" in relation to variegated plants, as it is suggestive either of recovery or dissolution; and variegated varieties of plants certainly do not appear to be a doomed race, as their existence can evidently be prolonged to an indefinite period with much the same ease and certainty as that of their green-leaved congeners. I write from memory, but, if I rightly recollect, some of your correspondents have asserted, that upon certain soils and by certain peculiarities of treatment, they can produce variegation at pleasure.

This may be the case, but I must confess that it is contrary to my experience on the subject.

It is easy enough to produce a blanched or sickly appearance, which under favourable influences will disappear, but this is evidently quite distinct from variegation.

But if it should be conceded that variegation is not disease, the question which will naturally present itself will be—If not disease, what, then, is it?

This question I unhesitatingly confess my inability to answer further than to say that I have always regarded it as an accidental peculiarity analogous to other phenomena occasionally occurring in the animal as well as in the vegetable kingdom, but the cause of which we have not as yet the means of ascertaining, but which peculiarities may and frequently are transmitted to succeeding generations in accordance with the recognised law of hereditary transmission of qualities.

Many years ago a summer's day found me angling in one of the tributaries of the "silvery Tweed." Some boys from an opposite bank of the stream threw a litter of kittens into the water, and, not very humanely, amused themselves by pelting them with stones. Soon after this the current bore the bodies of the little creatures near to where I stood, when I observed that one of them was minus the tail. I felt curious to ascertain if this appendage had been removed, or if it had never existed, and, on examination, I found the latter to be the case.

I then called at the cottage where the kittens had been brought from, and requested of the owner the favour of a personal interview with her cat. The old lady seemed somewhat surprised, but readily assented, assuring me at the same time that she (the cat) was a "rare gude mouser"—an assertion which I was not inclined to dispute. But a single glance at the interesting mother of the recent victims to the doctrine of Malthus convinced me that, in addition to her mousing qualities, she also rejoiced in the possession of a spinal continuation of the ordinary dimensions. And on careful inquiry I could not find that any tailless Grimalkin of the opposite sex was known to exist

in the neighbourhood; so this poor tailless kitten I considered as an accidental peculiarity, or sport, from which I did not doubt a race of tailless mouse-catchers might have been perpetuated.

A very few years since such a thing as a double-flowered *Petunia* was not thought of, but at last a double white variety accidentally, I suppose, made its appearance; but this variety, or sport, being what is termed a monstrosity, and destitute of an ovary, consequently could not produce seed, but it produced perfect pollen-bearing stamens, which cultivators were not slow to take advantage of, and the result is that double-flowered *Petunias* of various sizes and colours are now as common as the single-flowered varieties.

So it appears evident that when a sport is once obtained there is no mystery and but little difficulty in diversifying and improving upon it *ad infinitum*.

But if any of your correspondents can throw any light upon the cause or causes originating or producing these sports or peculiarities, their doing so will, I have no doubt, afford much gratification to a large portion of your readers.—G.

LINTON PARK,

THE SEAT OF LADY JULIA CORNWALLIS.

(Continued from page 220.)

The above is a view of the broad walk terminating in an octagon summer-house fitted up in a rustic manner. To the right of this walk the grounds extend a considerable distance southward; this being the Pinetum, and to the left of the walk

is one of the finest banks of Laurels we ever saw. Facing the walk and allowing about 2 feet from it for a grass verge, the cut Laurel rises perpendicularly about 3½ feet, then slopes back for about 3 feet at an angle of about 45°, and again rises

about 4 feet, after which it is sloped back a second time for some 6 feet or more at about the same angle as before. Some Fir trees form the background to this bank, which acts as an admirable shelter to the walk and Pinuses; and the Laurel-bank is in itself as good a piece of workmanship as can well be found. Our engraving only imperfectly shows it; but the accompanying diagram will help the reader

to understand it. The Laurels seem to endure the cutting very well, and the mechanical execution of the work was faultless. Mr. Robson told us that it was closely cut in about the second week in July with common hedge-shears; and as a little growth took place after that time, it was looked over in the autumn, and such shoots as were too long to remain the winter were thinned out with the knife, leaving the whole covered with such shoots as did not exceed 3 inches in length or so. This second growth looking so much better than a raw-cut face, the symmetry of the bank being still maintained

Ground level.

in all its integrity, and it would be impossible to improve it in any way.

The summer-house is a commodious place, the top being thatched with reeds, and the sides and floor coated with rustic wicker work, backed by a mass of shrubbery. This forms the most eastern portion of the grounds, and the view to the east and south-east from here is magnificent, while the robust health of the Pinuses equals that of any similar collection we have ever

seen. *Pinus insignis* assuming the attitude of a large timber tree, being densely clothed to the bottom, which is 38 feet in circumference. Some *Cedrus deodaras* are nearly as large; and *P. ponderosa*, a magnificent specimen, was almost as large, though thin of foliage, as is its habit compared with the others. The collection also contains excellent specimens of *P. pinsapo* and *cephalonica*, *Cryptomeria japonica*, some *Wellingtonia*, *Araucarias*, and other kinds, including a promising *Picea nobilis*, which, after losing its leader some years ago, has formed another, and seems disposed to make up for lost time.

We understand that very little loss was sustained here last winter, the natural dryness of the ground no doubt tending to lessen the evils of an unusually severe winter. Even the *Laurustinuses* were not prevented flowering, but some Tea and other Roses, as well as several plants not often trusted out of doors were also sufferers.

At a short distance from the commencement of the Laurel-bank alluded to, a noble Cork tree forms an important object, standing as it does in the centre of the broad walk. This tree, which has a symmetrical head, is upwards of 50 feet high, and the top spreads into a diameter of 56 feet, while the circumference of the bole about 6 feet from the ground is upwards of 8 feet. This tree is in admirable health, and promises to attain the proportions of indigenous trees. We were told it was something over eighty years old, and must have grown freely during the time, and to all appearance it is in as robust health as that of any other description of tree. We have been told it is the second finest tree of its kind in England, and so far as our observation goes it is the first. The bark wrinkles beautifully, and is of a pale buff or grey. The bark is also of considerable thickness, though, of course, removing it for use is quite out of the question in a position like this.

A A Ribbon-borders, three rows of bedding plants in each, with Pillar Roses festooned at top.
B B Ribbon-borders, having three rows of bedding plants.

As it is said no garden is complete without a rosarium, we append a ground plan of the one at Linton, which differs considerably from the general character of such features; for however beautiful Roses may be at certain times, there are periods when they certainly are not inviting, and many of the most esteemed varieties are the worst-looking at times when not in flower. On this account many growers have their Rose-beds at a distance from the mansion; but in the case before us means have been taken to render the rosarium attractive at all times. The pleasing forms of the beds and walks which, lying on a rather steep incline, are seen at a great distance, the white walks contrasting so well with the framework of turf by which they are intersected, and the gay ribbon-borders. Besides which the

pillar Roses which surround the whole have an interesting appearance. They are planted where the dots indicate, are about 8 feet high, and their tops festooned together, with an arch over the walk at each end, forming a complete circuit of the whole, the junction of the festoon-work and the arches being by a short horizontal bar between the two pillars that are about a yard apart; but as they have not been planted two years yet, the whole of the arches and chain-work are not yet covered, but they promise to be so early next season, and many of them are covered now. The two round beds at the ends are respectively of crimson and biush China Roses, and the central smaller bed was intended to be turf, but has been planted with its substitute, *Spergula pilifera*. It is right to say, that all the beds and turf

edgings, including this one, are edged with brick, as has been before described. The four large beds in the centre are dwarf Hybrid Perpetual Roses on their own roots, and being of good kinds, and the situation in every respect favourable for Roses doing well on their own roots, they bloomed well, and presented none of that irregularity of growth and vexatious suckers we so often see in worked plants; and though in other parts of the grounds we saw standard Roses occupying positions which could only be done by such like, they are only tolerated at Linton where plants on their own bottoms could not be had. In this garden, however, all were on their own roots, and excepting the climbers against the pillars all were dwarf. The four beds alluded to in addition to the edging of brick, had that much-neglected plant *Aubretia purpurea*, planted by the side of which entirely concealed it by its low-growing, compact habit. The two round beds were in like manner edged with Thrift, which sends up more rose-coloured blossoms during the summer than most people are aware of, who have not seen it in perfection. Four Irish Yews occupy the centre of the knobs of the turf frame at the inner borders, as well as the outer ones, all of which are something over a yard wide; and planted with bedding plants in summer, and in winter with Crocus and early spring-flowering plants, and by their shapes add materially to the general effect, and being planted with three rows of plants each, nothing could well look better than they did in August when we saw them. The planting was this—

The first outside border had the centre row of *Verbena Purple King*; the inner row next the walk *Calceolaria aurea floribunda*; and the outer row a white-edged *Geranium* called *Shottisham Pet*, which is here the greatest favourite *Geranium* in its way. The leaves being somewhat cuppy with a broad tip of pure white thrown upwards, look more rich than any flatter-leaved variety could do when looked at in a horizontal position. It is also a free grower. The appearance of this border was rich in the extreme, exceeding that of any other in the garden.

The corresponding border to the above was planted the same, only *Geranium Mangles* Variegated was substituted for *Shottisham Pet*. This did not look so well, although it was tolerably good.

The two inner borders were planted alike, with a scarlet horsehoe-marked *Geranium* in the centre, and on the concave side a strong-growing, pale blue *Lobelia*, which kept pace with the *Geranium*; and on the outer side next the grass margin was *Cineraria maritima*, which towards autumn became very rich, contrasting well with the great leaves of the *Geranium*, or even with the flower.

WORK FOR THE WEEK.

KITCHEN GARDEN.

LITTLE can be added to previous directions under this head. The operations of one week are an epitome of what has been, and still will be, necessary for some weeks to come. It is truly said that "necessity has no law," and it may as truly be said, that most of our operations at this season have no law as regards the time of performance; being entirely dependant on the state of the weather, common prudence will suggest to every one that no opportunity should be allowed to pass by of getting the soil as soon as possible in a favourable state for the reception of the various crops which must soon be committed to it, and as the basis of success is allowed by all good practical gardeners to be a thorough system of drainage, no time should be lost in attending to this most material point. As this kind of work can be done at any time when it is dry overhead, it is advisable to look to it without further delay. *Asparagus*, when making successional-beds, use a quantity of leaves with the dung, which will keep up a more moderate degree of heat, and retain it for a greater length of time than all dung. *Cabbages*, earth up, if not done, the weather now being favourable for that purpose. *Carrots*, if young ones are wanted very early, seed should now be sown in a slight hotbed. *Endive*, take advantage of a dry day to lay tiles over some of it in the open ground. Take up a portion of the best and lay in a frame, or shed, as a reserve in case of a severe frost. *Peas* and *Beans*, if frosts should be likely to set in severely, cover with partially decayed leaves those that are up. In favourable situations where neither forcing-houses nor pits are at command, another sowing may be made, but where even a common frame can be spared till March, it is

far preferable to sow in pots. *Radishes*, every fine mild day draw off the lights entirely, this will give them strength to form tap-roots.

FLOWER GARDEN.

Examine *Dahlia* roots to see that they are not rotting, for the want of this attention many persons are disappointed at finding them in the spring only fit for the rubbish-heap. A thorough cleaning should once more take place in all pleasure-grounds, as by this time all the decayed leaves are down. *Fuchsias* in beds or borders may be cut down and mulched over. If it is desirable to preserve any large specimens with their tops on, a row of stakes may be driven round in a circle and surrounded by a mat, the interior being stuffed loosely with clean new straw. The top to be thatched to exclude wet. Before enclosing it will be well to pluck off all the leaves, as they encourage mouldiness. Rustic baskets and vases planted in the summer to have the soil taken out of them in order to keep them from being injured by frost, and to prepare them for receiving fresh soil next spring. Where shrubberies are too thick, take up some of the best specimens and transplant them, and cut down inferior sorts.

FRUIT GARDEN.

Get all kinds of fruit bushes pruned, the prunings cleaned off, and the ground manured and forked over. Open out the centre of orchard trees for the admission of light and air, cutting out all dead wood and the branches that cross each other. The renewing of fruit-tree borders where the soil is impoverished is a very necessary operation at this season. Let as much of the old soil be removed as can be done without disturbing the roots, and its place be supplied with maiden loam. Avoid using stimulants, which often induce over-luxuriant growth without a corresponding degree of fruitfulness.

STOVE.

Where practicable, plant-houses ought to be covered with some waterproof material, or mats, in severe weather, especially the stove. Where mats are used they should be sewn together for the convenience of being rolled off and on as required. All plants, except a few *Orchids* and some bulbs, should now and for the next six weeks be quite at rest, and in that state 55° is high enough for them in cold weather. No more water to be given at the roots than will merely keep them from flagging; but some atmospheric moisture is always necessary, and requires some judgment to apportion it in accordance with external influences. A high dry atmosphere is more prejudicial to stove plants than the cold of a temperature as low as 50°.

GREENHOUSE AND CONSERVATORY.

Give air at every favourable opportunity, but not in currents; apply fire heat occasionally in the day with free air to dry up damp. *Azaleas* and *Camellias* to be kept cool, the forward plants being pushed forward with a little heat to expand their flowers properly. Shift on *Calceolarias* and *Cinerarias* as before. Supply water to such of the *Heaths* and *New Holland* plants as are coming into flower more liberally than to the others. Assist the early *Pelargoniums*; but keep the summer plants cool and airy. Remove *Chrysanthemums* out of flower to the foot of a wall. Keep *Chinese Primroses* near the light and air, and water cautiously.

FORCING-PIT.

Keep the heat at 65° at night with moisture, and never neglect to fill up every corner of this useful structure, for on it the greater portion of floral display for some months depends. Get in all kinds of Dutch bulbs, American and other flowering shrubs, *Lilies* of the Valley, *Heliotrops*, *Pinks*, *Roses*; and, in fact, all kinds of plants which are usually forced for decorating the conservatory and drawing-room. Keep down the green fly by occasional fumigations of tobacco.

PITS AND FRAMES.

Give *Auriculas*, *Polyanthuses*, *Camellias*, &c., air daily, either by tilting the lights or drawing them off. Keep the plants, particularly those with soft succulent leaves, free from weeds and litter. Keep the plants as dry as possible; and, if the atmosphere is damp, it is not a bad plan to dry it by placing a pan or two of burning charcoal in the pits, at the same time giving plenty of air: this should be done on a dry day.

W. KEANE.

DOINGS OF THE LAST WEEK.

ROUTINE.

The weather has been too wet for thoroughly cleaning the pleasure grounds, and hard-switching the walks before hard rolling; but we hope to do so directly as the glass is rising nicely again. Meanwhile every bit of decayed flower-beds has been made to do duty, in fermenting, to give out its heat to some useful purpose. Hollyhock-stems, when cut into small pieces, do admirably for this purpose, and especially in keeping somewhat open other vegetable matter that would run too closely together, to secure a mild, continuous heat. Cleared away the leaves from *Sua-kale*, and placed a little ashes over the crowns alike to protect them and to keep the frost out, so that they can be taken up for forcing at any time. Did the same with *Rhubarb*, and placed some rotten dung over *Asparagus*. Will use the first fermenting material we can get for a two-light box for sowing *Early Dutch* and *Early Horn Carrots* in, and a sprinkling of *Radi-shes* on the surface. The young *Carrots* in the open ground are useful for soups, &c. Covered pieces of *Endive* in earth-pits with stubble and leaves, to blanch it thoroughly. It blanches nicely if taken up and put into a collar or other dark place, but the stubble and a few leaves save all trouble in moving. Banked up the *Celery* also with stubble. In stiff soils this is better than using too much earth, and the blanching is equally well done, and wet thrust past, and frost kept out. Only the points of the leaves are fully exposed, and a small heap of stubble or other litter is left at the side ready to be thrown on in very severe frost. A few spruce branches are also useful for such a purpose.

COLD PITS, &c.

Occasion has been taken of the mild weather to give these all the air possible to prevent anything like damping taking place. *Caleolaria cuttings* planted out in the pit at the end of October are just rooting nicely, and not one seems to have gone out of thousands. We must keep these as backward as we can to save room; and, therefore, all the air possible, and every means to prevent elongation must be resorted to. We shall be able to give not more than about $\frac{1}{2}$ inch to each plant until the month of March, when we shall plant them out in protected beds; and if too close and crowded now, and we were obliged to cover them up as we did for six weeks last year, we should expect them to lose many of their lower leaves, and what is much worse, force us to have the bother and worry of picking them off. We hardly ever think of saving an old plant of these shrubby *Caleolarias*, for a little cutting inserted in October will be pretty well a better plant than the old one in May, and then we could keep from a score to a hundred in the space that would be required for one old plant. As stated some time ago, the having the plants too forward, and cramped in their roots before planting out, is one reason why so many people are forced to give up yellow *Caleolarias* for their beds. We hardly lost a plant last season, and the beds continued blooming freely until the cold frosty nights. They would not have done so in our dry climate last season without frequent watering and mulching. The season before 1850, was just the season here for them, but it was too wet for

SCARLET GERANIUMS.

We have, also, in addition, to similar care with *Scarlet Geraniums*, been forced to go over those especially that were struck in small pots—say from eight to ten plants round a small 60-pot, and pick off a few damping leaves and give them more room, as from growing a little they got into a perfect thicket. All these modes we have to resort to in the winter months to save room. After March or so we can resort to temporary protection and thus gain room. No doubt, time would be saved if we gave each of these small plants or cuttings a small pot to itself; but then we should scarcely find room for a tith of what we wanted. On the same principle we have no fault to find with those who can pot off their *Verbenas* and *Petunias* separately in the autumn. Want of room compels us to strike from a dozen or more in a small 60-pot, and when about this time they want much of care in watering, &c. We generally pot them in a piece just as they are into a 48, or even a 32-pot, and there they get strong and robust, and afford plenty of cuttings in spring; and these generally bloom better and thrive better than older plants, only we must keep some older for a stock. *Verbenas* also do well treated as we have mentioned for *Caleolarias*, placed out in a bed in the middle of September, in rows 2 inches apart, and 1 inch from plant to plant in the rows.

We have just given larger pots to those in 60's that were difficult to keep moist enough, and they will be easier kept though they take up more room than they did before.

Potted off singly into small pots *Alba Floribunda Geranium*, and other larly fancies, as *Kouge et Noir*, *Lady Mary Fox*, *Sidonia*, &c., as room could be got for them. We find all this section do best in beds when they have less or more of a ball; and when thus established in these little pots they can be turned out into boxes, or temporary beds under protection by the end of March, and may be moved to the flower-beds towards the end of May with a nice ball, and the fresh roots hanging all round it like a wig, ready to enter among the fresh soil; and thus treated they require far less attention than when kept all along in pots—in fact, in the matter of watering alone, a little drop of warmed water is placed on the soil round the roots when turned into the temporary beds, and they seldom need more before being finally planted. If we have room we do some *Scarlet's* the same way; but in general they do pretty nearly as well without balls as with them, though they do not look so well for the first week. Except where some *Grapes* are still hanging, we have no glass but what is full to overflowing at present.

Moved *Pelargoniums* where getting too thick, and stirring up the soil, and picking off any big leaf that showed the least signs of decay, leaving the forwardest unstoppped, and stopping any shoot extra strong in the succession, leaving the training and tying to some wet day; as, also, the cleaning and packing of seeds, &c. Prepared soil for potting *Ferns*, store plants, &c., as there is more leisure for such things now than in the spring of the year. Prepared a slight hotbed by means of tree leaves in a pit heated by hot water for placing the tenderest in immediately after shifting, so as to give the roots a fresh start.

Took all favourable opportunities for pruning, nailing, &c., choosing the best weather, as a man will do double in a warm sunny day, especially at nailing, that he can do in a cold damp day. Nailing in snow, and sleet, and heavy rains, we trust is numbered with the doings of the past years never to return again. They who keep men out even in wet days neutralise even their own selfishness; for besides the injury to health thus imparted, men so used cannot be expected to put their shoulders earnestly to the wheel when thorough exertion is required.—R. F.

ERRATUM—PAGE 222, 1st column, about middle, "large outside boxes," &c.—"boxes" should be "leaves."

TO CORRESPONDENTS.

* * * We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the "Journal of Horticulture, &c."* 162, Fleet Street, London, E.C.

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

We cannot reply privately to any communication unless under very special circumstances.

PEAR TREE INSECT (*Z. A.*).—The ravager of the Pear tree leaves in Somersetshire, leech-like in colour and shape, was the shiny grub, or larva of the Pear Saw-fly, *Salandria celtipis*. It is destroyed by dusting over the leaves with powdered quicklime.

TAN AS A MANURE (*C. G.*).—If well decayed it is a good general manure; but we should not depend upon that alone. As you cannot obtain stable manure, we should use the horse sewage mixed with it, and water the crops with a weak liquid manure of guano.

GEOMETRICAL GARDENS (*A Subscriber*).—There is no book especially on this subject for small gardens. Have you our "Flower-Gardening for the Many?" It contains several such designs.

VINE IN POTS (*Greyfriars*).—In these times of war-threatening the American papers come rather irregularly, but we will look out for what you need. If there is any particular point you need information upon write to us, we can obtain as good advice from gardeners on this side the Atlantic.

SCALE INSECT (*A Subscriber, Lichfield*).—We do not think the bark injured by the insect out at present, but it is liable to decrease the tree's vigour by stopping up the air-pores. You had much better use a creamy mixture of soft soap, flowers of sulphur, and water. The trees that have been treated with the insect oil we should scrub with a strong solution of common soda, such as washerwomen use.

WHAT A BOILER CAN HEAT (*A Subscriber*).—We cannot answer you satisfactorily without knowing the size of your boiler. If you have enough to do as it is, or may be capable of heating it while you propose. At any rate before we could say, we should require to know the size of the boiler, the quantity of piping it now heats, and the distance and position of the new pit from the boiler. In the meantime we commence in February. We do not suppose there is a pipe all round, or a flow of water beneath the bed, with earthenware pipes to let up the heat will be sufficient for a twelve-foot-wide pit. We think you will require the two pipes for bottom heat, and two for top heat. British patent glass will do for such a pit, but if you want to get a little more heating, and yet get sufficient light, you will find Hartley's best rough plate best.

FRUIT IN AN EAST ORCHARD—NOVEMBER—PRUNING AND POTTING ROSES (*A Subscriber*).—We have seen such trees ripen their fruit on east walls, and they will do so better under glass in an orchard-house having that aspect. Of Pears for such a house, Mr. Maréchal-Lévesque of Angoulême, Gien, Montargis, Wintzbourg, Van Momp, and Jersey. Pears of such a size as Peaches may still be potted, but not with such a good chance of setting their fruit as if done in September. If the pots are at all large, we would not report, but rather top-dress and let the roots run a little through the pots. When Orange trees are reported to be a good practice to give a little extra heat afterwards. The fire will do well enough if the roots are left stagnant afterwards. The Roses may be pruned in now, not cut down. The potting may now be done, but we would have preferred doing it in September. You could see in answer to another correspondent, that pruning and potting in the case of all plants, should not take place until next year's crop.

GREENGLASS PLANTING (*Prisona qui meruit ferri*).—It is only an original, not a new invention. Our plate at page 153, represents what was published in *La Belgique Horticole*, in the year 1850.

COCA-NUT FIRE (*L. M. R.*).—On the first page of our last Number there is an advertisement of where it is to be obtained.

YOUNG WOOD OF VINES (*A Constant Reader*).—You tell us that the wood of the Black Hamburgh is not so well ripened as that of the Muscat, but after examining the specimens we think that they are both perfectly ripened, and are of opinion that you would have no fear about next year's crop. The want of colour in the Black Hamburgh Grapes, probably arose from deficient air. Ventilate more freely in the summer and autumn.

COCA-NUT FIRE FOR RHODODENDRONS (*A Novice*).—Rhododendrons grow in some kinds of loam as well as in peat. On such loams the cocoa-nut fire will be of great use, but not take place until next year's crop. Rhododendrons would not grow naturally, the cocoa-nut refuse is of very little use indeed.

SCALE OR COCUS FLIGHT (*A Subscriber*).—We do not remember any offer of a prize for a description of the species. In the *Cottage Gardener's Dictionary* there are notices of all the common species under the head Coccus. We do not think it is worth the trouble of writing about it in the spring, with a thick mixture of soft soap, flowers of sulphur, and water.

BAKED ROUND TREES (*Idea*).—It is a barbarous and an unscientific proceeding splitting the bark. What is called bark-bird is only a deficiency of vigour. Scrub the bark with a hard braked dip in a brine of common salt, thin out the smaller branches, but do not cut away any large branches; and apply some lime to the roots.

CANKER (*Idea*).—It is a disease, an ulcer. The canker worm of the Bible has nothing whatever to do with such a disease.

COCA-NUT FIRE FOR PLUNGING (*Rev. C. D.*).—The cocoa-nut refuse is not at all suitable for keeping bottom heat for Cucumbers. In the first place, it does not heat of itself, and in the next place when it is exposed to a hot air chamber or draught, the surface of it dries to such a degree as to become a powerful non-conductor of heat, but where strong heat is not required, and where it is not liable to get dry, we believe it to be the best material for plunging pot plants in for a steady, mild bottom heat; that is Mr. Beaton's account of it, and we have it from Mr. Standish, of Bagshot, that as no worms or creeping things harbour in it, that it is the best thing to plunge pot plants in during the summer, it keeps the pots constantly damp, not the mould in the pots, and no enemy comes near them. He uses it in quantity for plunging in.

CULTURE OF IXIAS (*H. S.*).—The best way to grow *Ixias* of all sorts, is to have them potted at the very end of September, in rough peat and sand, in a medium state of moisture, a state in which they will not dry, and that state to be kept so till the leaves are 2 inches long above the pots, and the pots not to have a drop of water by hand all that time, if it lasted three months. The best way to keep the pots and their contents in that medium state, is to plunge them in the rain in sand or sifted ashes, or some loam refuse, but to have a shallow cover of turf or straw over them, but to also in a dry state, to be kept from frost and no more, and to have the light off every fine day, and dry during the whole winter. When the *Ixias* show for flower, they do it like *Stipa* in the field, then it is time to raise the pots, to wash them, and to place them in a dry greenhouse, where they will bloom from the middle of April to the end of May, then to rest till next potting time, and they should be kept in the same balls till then.

FUCHSIA SEEDLING (*C. T. H., Dorset*).—The white *Fuchsia microphylla* must be a very pretty thing; but as the old *microphylla* was clouded by the glaucous of the new proles, so will the white of it be by the larger whites.

SEEDLINGS OF PINUS INSIGNIS, EXCELSA, AND MORINDA (*Idea*).—The *Pinus* seedlings of last spring, now in pots, had better remain there just as they are to the middle of next April, then to be planted out in nursery-like rows in light soil.

NAMES OF PARTS (*R. M., Ireland*).—Apple.—No. 1, Parry's Pearmain; 2, not known; 3, Gold-n-Busset; 4, unknown, worthless; 5, White Costin; 6, unknown, worthless. G.—No. 1, Golden Wonder; 2, not known, we can hardly recognise it, but it appears to be Raisin de Catalogne; 3, Charles Masson.

NAMES OF PLANTS (*G. A., Clark*).—1, a form of *Lostraca filix-mas*; 2 and 4, ditto of *Polystichum angulare*; 3, ditto of *Lastraca dilatata*. They all look like the pebble and rather marked varieties, but are in too imperfect a state for further determination. No. 1, is especially promising in its appearance. *R. L.*—Cythra alternifolia, is a new plant, but we do not think it is new, cannot be named, except in rare cases, from single leaves. Nos. 3 and 4 are

alike. (*J. J., Durham*).—The leaf is, doubtless, that of some *Selaginium* plant, but in the absence of flowers and without any information as to the plant's habit, we are unable to recognise it. (*J. D., Fairfax*).—1, *Geranium molle*; 2, *Geranium columbinum*; 3, *Galium aparine*; 4, *Linum catharticum*, apparently, but such specimens cannot be named with certainty. Those who seek information ought to take the trouble to send well-selected flattened specimens, not confined to bits of herbage without flowers as these and many others which reach us are.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

CRYSTAL PALACE POULTRY SHOW.

DECEMBER 11TH—14TH.

It is an curious study to observe how the necessity of gaining a livelihood sharpens men's wits, and how they accommodate themselves to the circumstances that are likely to forward their designs. The most superficial observer cannot fail to be smitten with this. Take, for instance, the neighbourhood of the South-western terminus at Waterloo. In the early days when it was first opened good beds, luncheons, dinners were the inducements offered to weary travellers. When Southampton became the station for the Peninsular and Oriental boats, and Indians hurried up to London, those who keep houses of entertainment sought for something attractive to them. Now, the first thing that strikes them on leaving the station is that "Tilins" are to be had. This practice is not confined to shopkeepers, but pervades every class. If a review is advertised in Hyde Park, chairs, tables, and forms are brought from courts, alleys, Seven Dials, and St. Giles. Drinks of every kind are for sale on the ground and on the road. When the Serpentine is frozen over, ginger brandy and peppermint-balls and hot elder wine are the most saleable commodities. In the neighbourhood of the banking-houses in Lombard Street men offer for sale mahogany cases for pens, ink, paper, and envelopes. For a few shillings a man meets with a case akin in appearance to the highly-polished and substantial one he has just admired in Glyn's, Curtis', or Overend & Gurney's. With a correct judgment of character and a keen eye to business men select for their customers the more staid of the clerks who emerge from counting-houses of all kinds, and imagining them to be family men, they tempt them with glittering trays of shining bells, copper-scuttles, fire-irons, fire-places, and other articles of furniture for dolls' houses.

The Crystal Palace Company on a larger scale cater for Christmas people, and provide a treat in the shape of a poultry show. It was an experiment formerly, and is now a success, and a well-deserved one. It differs from many, inasmuch as there is here no Committee of Management—all devolves on Mr. Houghton, who is eminently successful in the undertaking. There are many advantages that belong to the Crystal Palace. It has no difficulty in finding a proper place for the exhibition. It has an unlimited staff of men from whom to choose for workers. Carpenters are at hand to make any alterations that violence, pugnacity, or other feelings may make necessary. To order extensive alterations, and to see them carried out, makes the man who gives the order look round to see if he has not become the possessor of Aladdin's lamp.

With these helps, it is no marvel if all the Shows are successes, and this is no exception.

The Spanish prizes in class I speak in the names of the successful, Messrs. Rake, Bull, Fowler, and Wright; it was a good contest, and the birds were of very high quality. The adults were in better condition than the chickens. Many of the combs of the young cocks were disposed to turn over at the back. Now, as these were free from thumb-mark or hollow, they should not droop or fall; and those who see this in their birds will know whether it proceeds from forcing or undue feeding. It is certain that several of the combs were too large and coarse. The comb on the head of a young Spanish cock should be as firm and upright as a military cockade. When we state that twelve pens were named by the Judges, it will be seen we are not condemning the class—we are only pointing out that which we believe to be an evil. The four prize pens were very good. The class for "two hens or pullets" does not bring as many entries as we expected—fourteen pens. Mr. Martin's were good ones, and so were Mr. Roods'; but, as a whole, these were not in high condition. There was much competition in the "single-cock class," which was strong, thirty-two entries represented most of our best yards; with the exception of Mr. Lane's bird, none call for special notice. In taking leave of our Spanish classes

we can speak highly as ever of the quality of the birds; but they were not in condition.

This Show is in the heart of the *Dorking* country; and it is, therefore, no marvel if these classes form an exhibition by themselves. Almost every yard of note is represented; seventy-two pens were deemed worthy of especial note by the Judges. *Lady Louisa Thynne* took five prizes, Mrs. Beardmore three, Captain Hornby two, Sir Joseph Paxton one. We have no hesitation in saying we have never seen a better show of this breed, and it was almost difficult to see the difference between the prize and commended pens; the competition was so close that the semblance of a defect, or almost the absence of a quality, caused defeat. We have so lately commented on the appearance of many of these birds at Birmingham that we need only say that many who do not figure as prizetakers are only excluded because there were no more to give, and not because their birds did not deserve the distinction; this will readily be believed of such birds as those shown by Messrs. Wakefield, Vernon, and others. In these classes the condition of the birds was admirable, and the size of many of the cocks was almost marvellous. The *White Dorkings* were very good.

Here, as at Birmingham, the adult *Cochin-Chinas* were very superior, maintaining the marked improvement they have shown this winter. With enormous size they have kept to beauty of form, and perfect colour and condition. Messrs. Tomkinson, Musgrove, and Stretch in these classes are what Kenble, Forbes, and Willett used to be in the Chancery Court—always before the public. The *Granse* and *Partridge* are daily becoming better and more numerous. Miss Musgrove and Mr. Tudman showed beautiful birds, and Mr. Bolton bids fair to rival them. He was a prizetaker in both classes. The *Whites* do not keep pace with the other colours. Mr. Chase has the best, and here took both the first prizes.

We are very glad to note the constant progress of the *Brahma Pouteras*. Messrs. Botham, Teebay, and Craigie have been their supporters through good and bad repute. They, therefore, deserve the honours they gain, when, the breed being fully known, success is more difficult. *Lady Louisa Thynne* showed good birds in this class.

The *Game* were excellent. Those classes that are usually weak, the *White* and *Piles*, were good, especially Mr. Cannon's and Mr. Monsey's. It is hard to resist the temptation of naming many of the *Game* that were successful and if all that deserved it appeared our report would be merely a repetition of the prize list. We must, then, be content with naming those that struck us most. Mr. W. Cox's first and second prize pens of *Black Reds* among the *Chickens*; Mr. Matthew's and Mr. Archer's among the old birds; Mr. E. Archer's *Brown-breasted Red* *Chickens*; and Mr. Parker's adults; Messrs. Langdale and Dawson's *Duckings*; with Mr. Vernon's and Messrs. Ballard and Dawson's *Blacks*, all merit especial mention. In these classes as usual, we have to remark the perfect condition of the birds and their exquisite feather.

In all *Pencilled Hamburgs* the adults look shabby in plumage compared to the chickens. The *Golden* chickens merited again that which we said of them last week. They were beautiful. Messrs. Nuttall, Munn, and Capt. Edgell may be proud of their birds. Mr. Martin would have had it all his own way in *Silver-pencilled*, but for Messrs. Wood and Bennett. *Golden-spangled* were very good, Mr. Lane had first and second, hard run by Mr. Dixon. Mr. Hyde showed the best chickens. In this breed the old birds show best. The *Silver-spangled* deserve mention for their merits as classes. There were twenty-two pens of *Chickens*, many of them very beautiful. *Lady Julia Cornwallis* showed capital birds, but was beaten by Mr. Hope in chickens, and Mr. Dixon in adults.

The *Pulands* were as good as we ever saw; there was only one class for each, and the entries were small. Mr. Pettatt showed perfect *Golden Chickens*. As much may be said of their respective classes of Messrs. Adkins, Edwards, and Dixon, who took the other prizes.

The *Malays* were very good, but not as numerous as usual. *Bantam* classes are every where improving. *Sobrighs*, *Game*, *Black*, and *White*, each is better this year than the last. In *Golden-pencilled* and *White*, Mr. H. D. Bayley always takes the prizes; in both he is closely followed by Mr. Cruwys. Mr. Leo stood alone in *Silvers*. The *Blacks* were excellent. All yield in numbers to the *Game*, and their quality was perfect. Messrs. Postans, Swift, and Allen may be proud, for they beat good exhibitors. There were some unusually good feathered-

legged *Bantams* shown in the "Various class." Mr. Forrest showed a remarkable *Duckling* in the *Bantam* *Cock* class.

Mr. Manfield did as he often does, he took both prizes for *White Geese*. His pens weighed 63½ lbs. and 52½ lbs. There were only two pens shown for *Grey* and *Mottled*. Mr. Fowler was and would have been first; his birds weighed 69½ lbs. He took his old position in *Aylesburys*, his birds being 22½ lbs. and 20½ lbs.

It was a hard run in *Roman Ducks*; the difference between Messrs. Fowler and Breavington being only half a pound—20 lbs. and 19½ lbs.; Mr. Punchedard was only 1 lb. lighter. The *Black Ducks* were perfect. Mr. H. D. Bayley's *Call Ducks* were as good as can be; the same gentleman showed beautiful *Sebastopol Geese*. Mr. Baker sent some *Barnacles* in good feather.

We must be content to give the weights of the *Turkeys*, seeing the length of our report. The old prize birds weighed 63 lbs. and 59 lbs.; the young birds, 56½ lbs., 56 lbs., and 54 lbs.

The *Game Cock Sweepstakes* filled to the number of thirty-four, and it was a difficulty to decide which were the best; there was hardly a bird that did not deserve a prize. Such as these deserve separate mention. We therefore say, the awards went thus:—Messrs. Dyas, Robson, Hindson, Keable, Sandford, Archer, Hindson.

Mr. Houghton was indefatigable, courteous, and painstaking as usual.

The following is the list of awards:—

SPANISH.—First, Miss M. L. Rake, Brandon Hill, Bristol. Second, W. R. Bull, Newport Pagnell, Bucks. Third, J. K. Fowler, Prebendal Farm, Aylesbury. Fourth, R. Wright, Holloway. Highly Commended, J. Martin, Mildenham Mill, Claines, Worcester. Miss M. L. Rake, B. Tebay, Fulwood, near Preston, Lancashire. **CHICKENS**.—First, J. R. Roblard, Aldwick Court, Winton, near Bristol. Second, Miss M. L. Rake. Third, H. Lane, Brit-ol. Fourth, R. Teebay. Highly Commended, C. Pedwell, North, Sussex; W. R. Bull, Newport Pagnell, Bucks; H. Lane, J. Martin, J. R. Roblard, Compton, J. Smith, Middlesex; J. W. Smith, Guildle, Northamptonshire. **GENS**.—First, J. Martin. Second, J. Rodd, 2, Princess Street, Cambridge Gate. Highly Commended, R. Wright. **COCKS**.—First, H. Lane. Second, J. Carr, Haul, Swansea, Glamorganshire. Third, R. Teebay. Highly Commended, R. Bull; H. Dawson, Cambridge, W. R. Bull, R. Rake; J. W. Smith, R. Teebay; A. Townend, Old Brompton. Commended, J. Martin; Miss M. L. Rake.

DORKING (Coloured).—First, *Lady L. Thynne*, Mantham Court, Worthing. Second, Capt. W. Hornby, R.N., Knowsley, Preston. Third, C. Chefield, Rock House, Wighton, Steyning, Sussex. Highly Commended, *Lady J. Cornwallis*, Little Park, Staplehurst; J. Frost, Parham, Suffolk; A. D. Hephurn, Clapham Common; C. H. Wakefield, Malvern Wells, Herez. First, E. H. Garrard, Clifton House, near Broadway. Second, *Lady L. Thynne*, Highly Commended, *Lady L. Thynne*, R. W. B. Bewick, Helmsley, York. **WATER**.—First, Capt. W. Hornby, R.N. Second, *Lady L. Thynne*. Third, J. Lewry, Blyne, Cuckfield, Sussex. Fourth, W. Tester, Green Trees Farm, Balcombe, Sussex. Highly Commended, *Lady J. Cornwallis*, Linton Park, Staplehurst; Sir J. Paxton, M.P., Rock Hills, Sycemham; Hon. W. Vernon, Barton Abbey, Stafford; Rev. M. Amphlett, Church Farm, near Excham; C. Baker, King's Road, Chelsea; B. Boys, Eastbourne; J. Cobley, Melton Mowbray, Leicestershire; J. Harris, Melton Mowbray, Leicestershire; A. D. Hephurn, Clapham Common; J. Lewry; J. McCallum, Commended, R. W. B. Bewick, Helmsley, York; J. Frost, Parham, Suffolk; E. H. Garrard, Clifton House, near Broadway; A. Potts, Hove Hall, Chester; W. Tester, *Pullets*.—First, Sir J. Paxton, M.P. Second, J. Lewry. Highly Commended, *Lady J. Cornwallis*; J. Lewry; C. H. Wakefield, Malvern Wells. Commended, *Lady L. Thynne*; W. DeBy, jun., Syston Old Hall, Grantham; P. A. Eagles, Godhards, Staplehurst. **DORCAS (White)**.—First, N. Antill, Pottsea, Hants. Second, Mrs. Beardmore, Uplands, Fareham, Hants. Highly Commended, Mrs. Beardmore; Mrs. H. Fookes, Whitechurch, Blandford, Dorset. **CHICKENS**.—First and Second, Mrs. Beardmore. Highly Commended, N. Antill; Mrs. H. Fookes. **BURNING COCKS (Coloured and White)**.—First, *Lady L. Thynne*, Mantham Court, Worthing. Second, Rev. J. G. A. Baker, Biggleswade, Beds. Third, T. Tatham, Kingsthorpe, Northampton. Highly Commended, *Lady M. Macdonald*, Woolner, Liphook, Hants; *Lady L. Thynne*, R. W. B. Bewick, Helmsley, York; Rev. E. H. Garrard, Excham; Rev. E. Cadogan, Walton Parsonage, Warwick; T. L. Biown, Chardleigh Green, Chard, Somerset; E. H. Garrard, Clifton House, near Broadway; J. Robinson, Vale House, near Garstang, Commended, Rev. J. F. Newton, Kirby-in-Cleveland, Yorkshire; H. Lingwood, Needham Market, Suffolk; J. Johnson; E. Tudman, Ash Grove, Whitechapel, Sloop.

COCHIN-CHINA (Cinnamon and Buff).—First, H. Tomkinson, Balsall Heath Road, Birmingham. Second, Miss V. W. Musgrove, Arington, near Ormskirk. Third, Mrs. H. Fookes, Whitechurch, Blandford, Dorset. Commended, H. Bates, Edgborough, Birmingham; T. Stretch, Boston, Liverpool. **CHICKENS**.—First, T. Stretch. Second, Miss V. W. Musgrove. Third, S. Statham, Forest Loos, Sussex. Highly Commended, Sir G. Gilbert, Claxton, Norwich; H. Bates; G. Johnson, Farnham, Surrey; J. W. Kelleway, Merston, Isle of Wight; J. McCallum, Hosh Distillery, Coleridge, N.B. Commended, Major F. C. Hasard, Hilses, near Foursome, H. Bates.

COCHIN-CHINA (Brown and Partridge-feathered).—First, Miss V. W. Musgrove, Arington, near Ormskirk. Second, Mrs. B. J. Ford, Countess Weir, Exeter. Third, J. Bolton, Birmingham. Commended, Mrs. E. Herbert, Exeter; E. Tudman, Ash Pouter, near Farnham, Surrey. **CHICKENS**.—First, T. Stretch, Boston, Liverpool. Second, J. Bolton. Commended, J. K. Fowler, Aylesbury, Bucks; T. Stretch, Bletchley, near Liverpool.

COCHIN-CHINA (White).—First, R. Chase, Moseley Road, Birmingham. Second, C. R. Titterton, Harborne, near Birmingham. Highly Commended, C. R. Titterton, Harborne, near Birmingham. Commended, C. R. Titterton. **CHICKENS**.—First, R. Chase. Second, C. R. Titterton. Highly Commended, W. Dawson Hopton; A. Peters, The Priory, Portsmouth.

CORNISH-CHINA COCKS (Coloured and White).—First, J. W. Kebley, Merston, Isle of Wight; Second, H. Ranson, Holbrook, near Ipswich. Highly Commended, Mrs. H. Pookes, Whitechurch, Hamford, Dorset. Commended, H. Tomlinson, Balsill Heath Road, Birmingham.

FRAMINGHAM (White).—First, R. Tebbay, Fulwood, near Ipswich, Lancashire. Second, G. Eaton, W. Winton, Top Wood, High Compton, W. G. K. Braxington, Victoria Farm, Hounslow. *Chickens*—First, Lady L. Thynne, Munition Court, Worthing. Second, R. Tebbay. Highly Commended, W. G. K. Braxington; J. H. Craigie, Woodlands, Chichester, Essex.

FRAMINGHAM (Coloured).—First, H. Craigie, Woodlands, Chichester, Essex. Second, T. Dunning, Mussell Hill, Highly Commended, R. Tebbay, Fulwood, Laneshire.

GAME FOWL (White and Piles).—First, J. Cann, Farnsild, Notts. Second, G. W. Hadley, White Plains, Birmingham. Third, J. Key, Monsey, Thorne Lane, Southwick. *Chickens*—First and Second, W. Burgess, Winton, Wiltshire. Hamford, Dorset.

GAME FOWL (Black-breasted Reds).—First, S. Matthew, Chilton Hill, Stowmarket, Suffolk. Second, E. Archer, Malvern. Third, A. B. Pynn, Madley, Shropshire. Highly Commended, R. Swift, Southwell, Notts. *Chickens*—First and Second, G. Cook, Balldob Hill, Derby. Third, R. Swift. Highly Commended, J. Keable, Thetford, Newbury, Berks; S. Matthew; Dr. Sewell, Bigwater. Commended, E. Archer, Malvern; W. Rogers, Woodbridge, Suffolk.

GAME FOWL (Brown-breasted and other Reds, except Black-breasted).—First, H. Parker, Wellington, Salop. Second, V. Sandford, Chatsworth Lodge, Marnham, Plymouth. Third, E. Pettit, Halstead, Essex. Highly Commended, E. Archer. Commended, Rev. T. L. Fellowes, Beighton Rectory, Ayle, Norfolk; R. Swift, Southwell, Notts. *Chickens*—First, E. Archer, Malvern. Second, R. B. Pynn, Madley, Shropshire. Third, H. Parker, Wellington, Salop. Highly Commended, J. H. Braltonridge, Chew Magna, near Bristol; S. Matthew, Chilton Hill, Suffolk. Commended, T. Burgess, jun., Whitbread, Notts.

GAME FOWL (Black and other Colours and Blues).—First, G. W. Langdale, Leckonfield Park, Beverley. Second, J. Hindson, Barton House, Everton, Liverpool. Third, R. Swift, Southwell, Notts. Highly Commended, J. Hindson; S. Matthew, Chilton Hill, Stowmarket, Suffolk. *Chickens*—First, W. Jackson, Selly Oak. Second, Hon. W. V. Vernon, Ramton Abbey, Warwick. Third, J. Brantley, G. S. Pynn, Madley, Shropshire. Fourth, H. T. Fiere, Barton Rectory, Diss, Norfolk; T. Hill, jun., Brentwood, Essex. Commended, E. Burton, Truro, Cornwall.

GAME (Black and any other variety).—First, W. Ballard, Woodcote Lodge, Leamington. Second, G. Bellwell, Walkley, near Sheffield. Highly Commended, W. Dawson, Selly Oak. *Chickens*—First, W. Dawson, Selly Oak. Second, W. Ballard. Highly Commended, V. Sandford, Chatsworth Lodge, Marnham, Plymouth.

HAMBOURG (Golden-pencilled).—First, J. Robinson, Vale House, Garstang. Second, J. Murray, near Hill, Strathclyde, near Manchester. Third, J. Choyce, jun., Harris Bridge, near Atherton. *Chickens*—First, A. Nuttall, Newchurch, near Manchester. Second, J. Munn. Third, Capt. R. Edgell, Bramford Spoke, near Exeter. Highly Commended, E. R. Clayton, Bramford Park, near Slough, Bucks. G. W. Locke, Newport, Isle of Wight. Commended, E. Payne, Cadini, Gloucestershire; W. Pierre, Hartford, near Northwich, Cheshire.

HAMBOURG (Silver-pencilled).—First, W. Wood, Sheffield. Second, J. Martin, Claines, Worcester. Third, W. Bennett, Brockham Lodge, Betchworth. *Chickens*—First and Second, W. Bennett, Brockham Lodge, Betchworth; J. Martin, Claines, Worcester.

HAMBOURG COCKS (Gold or Silver-pencilled).—First, J. Munn, Stakesteads, near Manchester. Second, E. A. Wilkinson, Birmingham. Highly Commended, F. Armstrong, Leyce, Bedford. Third, W. Bennett, Brockham Lodge, Betchworth; J. Martin, Claines, Worcester.

HAMBOURG (Golden-spangled).—First and Second, W. R. Lane, Bristol Road, Birmingham. Third, J. Dixon, Bradford. Commended, G. Brook, Hathersfield. *Chickens*—First, W. R. Lane, Bristol Road, Birmingham. Second, H. W. E. Derwick, Helmley, York. Third, G. Brook, Commended, I. Davis, Harborne, near Birmingham; J. Hope, Oldham; T. May, Wolverhampton.

HAMBOURG (Silver-spangled).—First, J. Dixon, Bradford. Second, R. Tebbay, Fulwood, near Ipswich, Lancashire. Third, H. Beal, Wexham Grove, Slough. *Chickens*—First, J. Hope, Oldham. Second, Lady J. Cornwallis, Linton Park, St. John's, third, Mrs. H. Sharp, Bradford, Yorkshire. Highly Commended, H. Carter, Upperting, Holmfirth; J. Fielding, Newchurch, near Manchester. Commended, H. Beal, J. Dixon.

HAMBOURG COCKS (Gold or Silver-spangled).—First, H. Hyde, Ashton-under-Lyne. Second, Lady J. Cornwallis, Linton Park, Staplehurst. Commended, H. Carter, Upperting, Holmfirth.

HELANE (Black with White Crest).—First and Third, T. P. Edwards, Lyndhurst, Hants. Second, J. Dixon, Bradford, Yorkshire. Highly Commended, Mrs. H. Sharp, Bradford, Yorkshire. Commended, J. Smith, Keighley.

POLAND (Golden).—First, J. Dixon, Bradford. Second and Third, Mrs. P. Lake, Easingby, York.

POLAND (Silver).—First, J. Dixon, Bradford, Yorkshire. Second, G. C. Adkins, the Lightwoods, near Birmingham. Third, withheld.

POLAND COCKS—First and Second, G. C. Adkins, Birmingham.

MALAY—First, C. Pallance, Taunton, Somerset. Second, J. Rumsey, Shadwell, High Wycombe. Third, W. Bennett, Brockham Lodge, Betchworth. *Chickens*—First, N. Sykes, jun., Mile End. Second, W. Manfield, jun., W. G. K.

ANY OTHER DISTINCT BLOOD—First, E. Hutton, Pudsey, near Leeds (Black Hamburgs). Second, C. Baker, King's Road, Chelsea (Crève Coeur). Third, W. Dawson, Hutton Mithel, Yorkshire (Sultans). Fourth, Lady Thynne, Munition Court, Worthing (Sultans). Highly Commended, C. Coles, Fareham, Hants (Andalusian); J. Hope, Oldham (Black Hamburgs); T. Walton, Charwelton, Daventry (Sultans); Mrs. E. Pizeon, Lympstone, Devon (Black Cockins); T. Wilson, Chapel Street, Park Lane, (White Poland). Commended, W. Bennett, Brockham Lodge, Betchworth.

BANTAMS (Gold laced).—First, T. H. D. Bayly, Biggleswade, Beds. Second, Rev. G. S. Cruwys, Crawley Moorhead, Tiverton. Highly Commended, W. Cooper, Swallowfield, Reading; L. M. Lenox, Markyate street, Herts. Commended, S. Hill, Claxton, York.

BANTAMS (Silver-laced).—First and Second, M. Leno, jun., Markyate Street, Herts. Commended, Rev. G. S. Cruwys, Crawley Moorhead, Tiverton; T. H. D. Bayly, Biggleswade, Beds; F. White, Clapham Common.

BANTAMS (White, clean legs).—First, T. H. D. Bayly, Biggleswade, Beds.

Second, Rev. G. S. Cruwys, Crawley Moorhead, Tiverton. Highly Commended, I. Binsley, Shadwell; Master E. Wylie, Turham Green.

BANTAMS (Black, clean legs).—First, E. Hutton, Pudsey, near Leeds. Second, G. Bradwell, Southwell, Notts. Highly Commended, G. Bradwell.

BANTAMS (Game).—First, H. B. Postans, Brentwood, Essex. Second, R. Swift, Southwell, Notts. Third, F. S. Allen, Bourne, Gloucestershire county. *Cock*. Highly Commended, Right Hon. Lady Ash, urton, the Grange, Alresford, Hants; J. Cann, Farnsild, Notts; M. Leno, jun., Markyate Street, Herts; E. B. Postans; H. Shield, Northampton. Commended, T. H. D. Bayly, Biggleswade, Beds; E. Burton, Truro, Cornwall; R. Hawksley, jun., Southwell, Notts.

BANTAMS (any other variety).—First, Mrs. Green, Lower Church, Surrey (Siab King) fow, from Wooming, China). Second, G. Durr, Hallowston, Southwell, Notts (Footed Bantams). Highly Commended, W. Brown, Shute, Southwick, Notts (Siab Bantams, from Algiers); H. Shield, Northampton (Spangled Game Bantams).

BATAVIAN COCKS.—First, W. S. Forrest, Greenhithe, Kent. Second, H. Ayles, Lympstone, Devon. Highly Commended, T. H. D. Bayly, Ickwell House, Baginbode, Beds; Mrs. Beardmore, Fareham, Hants; G. Nicholson, Fareham, Hants; H. Shield, Northampton; W. Fowler, jun., G. G. K.

GLESE (White).—First and second, W. Manfield, jun., Portesham and Dorchester. Highly Commended, W. Manfield, jun.

GLESE (Grey and Mottled).—First, J. K. Fowler, Aylesbury, Bucks. Second, W. Brown, Kidgate Farm, Shute, Devon.

DUCKS (Aylesbury).—First and Second, J. K. Fowler, Aylesbury, Bucks. Third Mrs. Pattinson, Malden, Essex. Highly Commended, J. K. Fowler; J. Harris, Melton Woodbury, Leicestershire. Commended, W. Syson, Debach, near Woodbridge, Suffolk.

DUCKS (any other variety).—First, J. K. Fowler, Aylesbury, Bucks. Second, W. G. K. Braxington, Victoria Farm, Hounslow. Third, C. Pun-hard, Blunts Hill, Suffolk. Highly Commended, Rev. H. G. Bally, Swinson, Wilts; W. G. K. Braxington, J. K. Fowler.

DUCKS (any other variety).—First, T. H. D. Bayly, Biggleswade, Beds. (Call Ducks). Third, T. Smith, Lewes, Sussex (Muscovy Ducks). Second, withheld.

ORNAMENTAL WATER FOWL.—First, T. H. D. Bayly, Biggleswade, Beds. (Schostoff Geese). Second, C. Baker, King's Road, Chelsea (Bernice Geese). Third, W. Manfield, jun., Portesham and Dorchester (China Geese).

TEKELAS.—First, J. Smith, Breder Hills, Grantham. Second, W. Manfield, jun., Portesham and Dorchester. Third, R. Brand, Great Shelford, Cambridgeshire. *Fowls*. First, Second, and Third, R. Brand, Great Shelford, Cambridgeshire. Highly Commended, Lady St. Macdonald, Wimoor, Liphook, Hants; Rev. T. L. F. Doves, Beighton Rectory, Ayle, Norfolk; J. Smith, Breder Hills, Grantham. Commended, E. Guy, Eaton, near Grantham.

TEKELAS (Silver Pheasants).—First, S. C. Betty, Gloster Gate, Regent's Park, G. G. K. Second, Mrs. Pattinson, Malden, Essex (Silver).

PHAEASANTS (any other variety).—First, M. Leno, jun., Markyate Street, Herts (Chinese Ring-neck). Second, C. Baker, King's Road, Chelsea (Chinese Ring-neck).

PHAEASANTS (any other variety).—First, A. B. Pynn, Madley, Shropshire. Second, W. Robson, Carlton Road, Worksop. Third and Seventh, J. Hindson, Barton House, Liverpool. Fourth, J. Keable, Thetford, Newbury, Berks. Fifth, V. Sandford, Chatsworth Lodge, Marnham, Plymouth. Sixth, E. Archer, Malvern. Highly Commended, Hon. W. V. Vernon, Barton Abbey, Stafford; E. Pinner, S. M. New, Chilton Hill, Strathclyde, Suffolk; H. E. Porter, York Place, St. John's Wood; W. Robson, Worksop.

PIGEONS AND RABBITS.

THE Show of Pigeons and Rabbits at the Crystal Palace was more than usually numerous, there being 314 pens of the former and 109 of the latter exhibited. In respect both of the number and quality there was a great improvement on all the previous Shows. We should be glad to have been able to say the same of the arrangements, which were decidedly inferior to those of many fifth-rate local exhibitions. The majority of the birds—more especially those which required the closest and most minute inspection to distinguish their points and properties—were arranged on two sides of a narrow alley barely two yards in width, one end of which only was lighted. The pens were placed in three tiers or rows one above the other, so that it was practically impossible to see the birds in the lower tier; and after spending four hours in the inspection of the Pigeons and Rabbits, we left without having had an opportunity of seeing several of the prize birds. As if to add to the inconvenience of this narrow crowded passage, the water-pans were placed outside, and as they were nearly as low as the levels of the knee, they were constantly being upset over the dresses of the ladies and the coat-tails of the gentlemen. When we state that the evils here complained of could have been readily obviated by moving one side of the alley back some 20 feet or even 10 feet, into an empty space behind, it is obvious we do not complain of the arrangements without a cause.

Again, except in the cases of the pens of one or two exhibitors who were shrewd enough to provide their own food-pans, there were no means of feeding the Carriers except by throwing the food on the floor of the pens. This is always an objectionable plan, as the food becomes contaminated with the dung and injures the birds; but in the case of Carriers it is a fatal

practice, for a stout bird cannot see before it to pick up a bean, and often makes a score of vain attempts in succession.

The first class was for *Powter-cocks*. The second and third prize went to birds both belonging to Mr. Rake, a Blue and a Black Pied, both are standard birds that have won numerous prizes. The first prize was awarded to a coarse, thick-bodied Mealy, that was nearly heavy enough to win in the Runt class.

In *Powter hens* Mr. Rake won with an excellent Blue. Mr. Evans taking second with a very superior long *Grizzle* that we noticed at the last summer Show.

In *Carriers* a revolution was effected: the Plymouth birds, distinguished by their remarkable style and carriage, took away many of the prizes from the more heavily-wattled birds of other exhibitors. In Black cocks, Mr. Goss, of Plymouth, took first. Mr. Stevens second, and Mr. Colley third, with a very stout bird. In Blues, Mr. Colley was again successful.

In the *Dragon* classes, Mr. Stevens took first with a pair of *Yellows*, very good in colour.

In *Almond Tumblers*, the first prize went to a pen of Mr. Corker's, unquestionably the best pair in the Show, although the cock was rather dark in colour from age, and the wonderful short face of the hen had been evidently unproved by judicious management. Mr. Rake's second and third prize pens were good, but rather deficient in colour.

In *Short-faced Mottles*, Mr. Corker was again successful with a pair of good Blacks, closely followed by Mr. Esquilant's second-prize pen.

In the *Short-faced Baldhead and Beard* classes, the prizes went to invisible blues, far from the position of the pens in the bottom row of the narrow alley, we found it impossible to see the winning birds, although we have seen them on other occasions, and know them to be very good.

We now come to a new class, one for *Kites, Agates*, and other self-coloured *Short-faced Tumblers*. We claim credit to ourselves for the establishment of this class, its existence being evidently owing to our remarks on the practice followed at the last Show of giving prizes to *Kites* as self-coloured *Tumblers*. The prize was awarded to Mr. Percivall's *Kites*.

Jacobins as a class were neither numerous nor good. In *Blue and Silver Owls* the competition was entirely between two pens belonging to Mr. Morris and Mr. Rake. The prize was awarded to the former, the latter being highly commended. Several fanciers thought the hen of Mr. Rake so much better in the head than that of Mr. Morris, that they would have transferred the position.

In *Owls* of any other colour Mr. Rake won with the most perfect pair of small Whites we have seen; as a proof of the estimation in which these birds are held, we may state that two hens not commended were claimed at £5. The Judges append the remark that this was the most beautiful class of *Owls* ever exhibited; and, yet, strange to say, they did not commend a single pen! It cannot be said that the whole class were commended, inasmuch as there were two or three very inferior pens contained in it.

In the class of *Turbits* the first-prize birds of Major Cook appeared to wear the characteristic frog-like head so peculiar to the breed.

In the *Black Fantails* the prize was withheld. The White variety prize was awarded to turned-crowned birds. The class of Blue consisted of three entries only, and contained nothing remarkable.

In *Barbs* Mr. Rake won with good Blacks, Mr. P. Jones with Reds.

The *Mottled Trumpeters* were not remarkable; in the White or other coloured the prize was awarded to a middling pen of Blacks, Mr. Key's well-known pair of Whites not being noticed.

The class of *Runts* was very good. Mr. Green sent in six good pens, winning with a good pair of Blues; his highly commended Silvers we thought unusually excellent.

The *Extra Variety* class was very good. Mr. Goore most deservedly took first for a new variety termed *Russians*; they may be described as rock-headed birds, with bald heads and a turn crown like a Blue Priest; but the entire of the remainder of the plumage was of the most delicate silver, and the absence of bars on the wings made them especially striking.

Two pairs of the coarse *Long-faced Beards*, so much esteemed by many of the London fanciers, were shown, but they did not attract the notice of the Judges.

Upwards of 100 pens of Rabbits were exhibited, constituting by far the best collection ever seen in the Crystal Palace. The

first prize for the longest ears was given to a *Tortoiseshell buck*, age seven months, belonging to Messrs. Guest & Coleman. His ears were longer than those of any Rabbit previously shown here, measuring over 23 inches, and, doubtless, with a little gentle extension they might be made to stretch still longer.

Mr. Stedman won both prizes for *Black and White*.

The *Yellow and White* of Mr. Hindes was a very good rich-coloured doe. Mr. Morris' prize *Tortoiseshell* was in first-rate condition. Messrs. Guest & Coleman's *Blue and White* prize doe was remarkable for the correctness of its markings; and the colour of Mr. Hindes's *Fawn doe* was very good. For weight the prize went to a *Grey and White doe* of Mr. Rodgers. We could not learn her exact weight, but were informed that she was the heaviest ever exhibited at the Palace.

The prizes for foreign Rabbits were awarded to a *Grey Alpine buck* belonging to Dr. R. Hogg and a *buff-floured Silver Grey* belonging to Mr. Vipian.

As a whole the show of Rabbits far exceeded in quality as well as number those of previous years.

PIGEONS.

POWTERS OR CROPPERS (any colour).—Cocks.—First, T. H. Evans, Lambeth Walk. Second and Third, M. Rake, Brandon Hill, Bristol. Highly Commended, E. L. Corker, Croydon; R. Fulton, Devonport. Commented, T. H. Evan; C. J. Samuels, Victoria Park, Manchester. (A good class.)
Hens.—First, M. Rake, second and Third, T. H. Evans. Highly Commended, E. L. Corker, Croydon. Commented, T. Colley.

CARRIERS (Black and Dun)—Cocks.—First, P. Goss, Plymouth. Second, F. G. Stevens, Axminster, Devon. Third, T. Colley, Sheffield. Highly Commended, J. Barstow, Halifax; P. Goss; E. J. J. Humes, Lewisham. Commented, Major E. C. Hassard, Hilson, Portsmouth; E. L. Corker, Croydon; M. Rake, Brandon Hill, Bristol. Hens.—First and Second, T. Colley. Highly Commended, J. Barstow. Hens (Black and Dun)—First and Second, P. Goss. Third, E. L. Corker. Highly Commended, E. L. Corker; P. Goss. (A good class.) Any other colour.—First, T. Colley. Second, J. E. Liston.

DRAGONS.—Blue.—Prize, G. Graham, New Charlton. Highly Commended, A. L. Silvester, Birmingham; G. F. Treadaway, Paolington. Any other colour.—Prize, F. G. Stevens, Axminster, Devon. Highly Commended, C. J. Samuels, the Elms, Victoria Park, Manchester; F. G. Stevens.

ALMOND TUMBLERS.—First, E. L. Corker, Croydon. Second and Third, M. Rake, Brandon Hill, Bristol.

SHORT-FACED MOTTLES.—First, E. L. Corker, Croydon. Second, F. Esquilant, Oxford Street.

SHORT-FACED BALDHEADS.—First, F. Esquilant, Oxford Street. Second, J. W. Edge, Aston New Town, Birmingham.

SHORT-FACED BEARDS.—First, E. Archer, Malvern, Second, M. Rake, Brandon Hill, Bristol.

SHORT-FACED TUMBLERS (Self Colours).—First, J. Percivall, Rye Lane, Peckham. Second, F. Cannon, Bradford, Yorkshire. Highly Commended, E. L. Corker, Croydon.

KITES, AGATES, DUNS, AND GRIZZLES.—Prize, J. Percivall, Rye Lane, Peckham.

JACOBIENS.—First, G. F. Nicholls, the Moors, near Cheltenham. Second, F. Esquilant, Oxford Street. Commented, F. G. Stevens, Axminster, Devon.

OWLS (Blue or Silver).—Prize, H. Morris, Sreedale Lodge, Forest Hill. Highly Commended, M. Rake, Brandon Hill, Bristol. Commented, Rev. F. Watson, Woodbridge, Suffolk; W. Cannon, Bradford, Yorks; J. Thoms, Canons, Oxford; or any other colour.—Prize, M. Rake, Brandon Hill, Bristol. (Most beautiful class of *Owls* ever exhibited.)

NESS.—First, F. Key, Beverley. Second, G. C. Adams, the Lightwoods, near Birmingham.

TURBITS.—First, Major W. S. Cook, Stoke St. Mary, Somerset. Second, G. F. Nicholls, the Moors, near Cheltenham. Third, G. C. Adkins, the Lightwoods, near Birmingham. Highly Commended, F. E. Else, Payswater.

FANTAILS.—White.—Prize, E. Archer, Forest Hill, Kent. Highly Commended, G. Goore, Aigburth Vale, near Liverpool. Commented, H. Morris, Silverdale Lodge, Forest Hill. Blue.—Prize, J. Baily, jun., Mount Street.

BARBS.—Blue.—Prize, M. Rake, Brandon Hill, Bristol. Highly Commended, C. Baker, King's Road, Chelsea; P. H. Jones, Fulham; F. G. Stevens, Axminster. Yellow, or any other colour.—Prize, P. R. Jones. Highly Commended, F. G. Stevens. Commented, M. Rake.

MICE.—First, G. F. Nicholls, the Moors, near Cheltenham. Second, G. Fleming, Albert Road, Peckham. Third, F. E. Else, Westbourne Grove, Payswater. Highly Commended, F. G. Stevens, Axminster, Devon.

TRUMPETERS.—Black Mottled.—Prize, J. Baily, jun., Mount Street. Commented, W. Cannon, Bradford, Yorkshire; F. G. Stevens, Axminster, Devon. *White or any other variety*.—Prize, J. Baily, jun. Commented, J. Baily, jun. & S. WBS.

SPANISH AND LEBRON RUNTS.—First, T. D. Green, Saffron Walden, Essex. Second, F. Key, Beverley. Highly Commended, C. Baker, King's Road, Chelsea. (A very good class.)

FOR AN NEW OR DEEVEYING VARIETY (not before mentioned).—First, G. Goore, Aigburth Vale, near Liverpool (Russians). Second, H. Morris, Silverdale Lodge, Forest Hill. Third, J. Simmons, Fareham, Hants (Foreign Wood Pigeons). Fourth, E. A. Hargrove, Villa Road, Birmingham. Commented, J. Baily, jun., Mount Street (Isabell).

RABBITS.

LONGEST EARS.—First, Messrs. Guest & Coleman, Birmingham (Tortoiseshell buck). Second, J. Hindes, jun., Hall Green, near Birmingham (Grey Buck). Highly Commended, J. Angus, Rye Lane, Peckham (Black Buck); Messrs. Soles & Butler, Orchard Place, Woodwich (Black and White Buck).

BLACK AND WHITE.—First and Second, A. Stedman, Oxford, Surrey (Doe). Highly Commended, J. Hewitt, Birmingham (Eck); G. Jones, Birmingham (Buck). Commented, Messrs. Guest & Coleman, Birmingham (Buck); Miss M. Hawksey, Edgeware Road (Doe); C. Selten, Surrey (Lack).

YELLOW AND WHITE.—First, H. Hindes, jun., Norwich (Doe). Second, J. Hindes, jun., Birmingham (Doe). Highly Commended, J. Hindes, jun.

(Buck).—H. Hades, jun. (Buck). Commended, R. B. Newson, Brixton Hill (Buck); J. G. Quick, Portland Town (Buck); A. Steiman, Oxford, Surrey (Buck).

TORTOISE-SHELL.—First and Second, J. Morris, jun., Silverdale Lodge, Forest Hill (Doe). Commended, Miss H. Haslede, E. Ince, E. and L. (Buck); J. Hicks, jun., Birmingham (Doe); H. Hibbes, jun., Newnch (Buck); H. Hoyle, Nottingham (Doe); C. Selten, Surrey (Buck).

BLUE AND WHITE.—First, Messrs. Guest & Coleman, Birmingham (Doe). Second, Rev. C. P. McCarthy, Wallon Green (Buck). Highly Commended, W. Griffin, Bull Fields, Plumstead (Doe); J. Hewitt, Birmingham (Buck). Commended, W. Griffin, Messrs. Guest & Coleman.

GREY AND WHITE.—Commended, J. Stanton, Holloway (Buck).

SELF COLOURED.—First, J. Hicks, jun., Hall Green, near Birmingham (Fawn Doe). Second, E. Buckley, Greenwell Fawn Buck. Highly Commended, E. W. Brough, Union Street, Leicestershire (Fawn Buck and Grey Buck); J. Hicks, jun. (Fawn Doe). Commended, J. Grover, Deptford (White Buck); W. Nott, Chelsea (Doe); C. Selten, Surrey (Sooty Fawn Doe); Messrs. Sole & Butler, Woolwich (Black Buck); D. Thorne, Holloway (Buck).

FOY WEIGHT.—First, H. Rodgers, Brampton, near Chesterfield (Brown and White Doe). Second, G. Jones, Market Hall, Birmingham (Fawn Doe). Highly Commended, C. Collins, Molland Street, Birmingham (Yellow and White Doe); G. Rome, Southover Street, Brighton (Tortoiseshell Doe). Commended, E. Brough, Union Street, Leic.; J. G. Quick, Henry Street, Portland Town (Tortoiseshell Doe).

FORBYS RAFFLES.—First, Dr. R. Hogg, Winchester Street, Fimble (Alpine Buck). Second, E. J. Vipan, St. Ives, Hun's (Buff-coloured Silver Grey Buck).

JUDGES OF POULTRY.—Messrs. Andrews, Baily, and Hewitt. PIGEONS.—Messrs. Bellamy and Cottle. RABBITS.—Messrs. Fox, Housden, and Webster.

BIRMINGHAM GUEST EXHIBITION.

I HAVE perused with interest the excellent report of this our greatest of poultry shows, inserted in your last week's paper. It leaves but little to be said on the subject of the poultry generally, still there were fresh arrangements this year that seemed to arrest the attention of exhibitors in no small degree, and that from their importance call for especial mention. It appears that the managing Committee, with the laudable intention of rendering the Exhibition at Bingley Hall, as a whole, a subject of still more general interest, have this year contracted the accommodation hitherto enjoyed by the poultry to that bay alone that was built expressly for this department of the Exhibition. For some years past the Geese, the Turkeys, and the Ducks, together with the whole of the Pigeons, have found their fixture outside this bay, and being a most extensive portion of the whole, relieved the crowding that must of necessity have taken place had they been restricted exclusively to the portion of the building just named. The ground they have hitherto occupied has this year been given up to a display of agricultural implements. No doubt the inspection of this fresh feature was a matter of interest to many visitors, solely on account of its novelty; but to the owners of no small number of the valuable pens of poultry exhibited, it afforded rather a subject for regret than any such change had been instituted.

To say that the Bingley Hall Exhibition derives almost the whole of its present popularity from its poultry is a suggestion few, if any, will deny, and consequently whether to limit this particular portion of the Show is a prudent measure is open to much doubt and question. Having, therefore, to grapple with the combined difficulties of an increased amount of entries, coupled with a greatly lessened amount of space, the only course that possibly could be pursued, was decreasing the size of each particular pen very considerably. As a further relief, a cock and two hens, instead of a cock and three hens (a feature in poultry shows in which Birmingham has hitherto stood without a rival), became in 1861 a newly-appointed regulation. With this brief explication, it is well to briefly jot down the results. To any one in the slightest degree conversant with poultry matters, it was painfully apparent that the pens allotted to the Dorkings, Cochins, Brahmas Pouteras—in fact, to each of the very largest varieties, were unquestionably too small. It was only with difficulty such birds could pass each other, and for two out of the three birds (so-called) to stand together at the front of their pen proved almost an impossibility. The owners of such poultry could scarcely be supposed to look approvingly on this curtailment, whilst intending purchasers and visitors generally were obliged to be satisfied with a less satisfactory inspection than that in years past.

The taking away one hen from each pen, deprived likewise many poultry amateurs desirous of purchasing of one of the greatest boons Birmingham always offered them. A pen purchased with three well-matched hens, at the Shows hitherto, had this prominent advantage—in case from death or lapse of con-

dition one hen went amiss, the two remaining ones still held good for any other meeting in the Kingdom. Such a mishap in the case of two hens only obviously throws the purchaser into the shade altogether, or subjects him, at the least, to the greatly-increased difficulty and expense of finding a match single bird elsewhere.

In the smaller varieties of poultry and the Pigeons, the accommodation permitted to each pen was unquestionably quite sufficient.

To all breeders of poultry, it is needless to do more than mention, that the absolute injury arising from confinement is always proportionate to the room or compression permitted them, shortness of space, too, telling still more severely as each day is added to their imprisonment. It is the prevailing hope of most exhibitors of the larger varieties, that in future some little amelioration of present plans will be granted them.

I cannot forbear a brief reference to a circumstance that seemed to cast a very general gloom among the poultry amateurs assembled, arising from the death of that well-known local amateur and breeder, Mr. George Peters. Twelve pens were entered for exhibition at this Show, but only the day preceding the arbitrations their owner was himself consigned to the tomb, and, therefore, the birds were not forwarded.

By the death of Mr. Peters, an extended circle of his equals are deprived of a really frank and open-hearted friend, whilst the poor of his neighbourhood deplore their still more irreparable loss of ever-willing sympathy and advice, combined with the ready hand of a truly liberal and generous benefactor.

UPON reaching Birmingham on Monday last, I was surprised to find Mr. Hewitt had not assisted in awarding the prizes. Perhaps some of your readers can mention why his services were rejected. Does Mr. Hewitt charge more than the other Judges do, or do the Committee consider him after so much practice incapable? I fancy, for the last ten years Mr. Hewitt has judged at least six shows for either of the others' one.—INQUIRER.

[The above is from a well-known poultry exhibitor. We were not aware, until we saw a list of the Judges, that Mr. Hewitt was not one of them; and we now only express the hope of all honest poultry exhibitors when we say that we trust Mr. Hewitt's absence from that list will not be permanent. We believe it will not, for we are informed that it arose from causes easily removable; and, therefore, no public discussion is needed.—EDS.]

THE THREE GREAT CENTRAL SHOWS OF ENGLAND.

At the time of presenting a testimonial to Mr. Joseph Stephenson, C.F., at Darlington, for "his exertions during nine years in superintending the carrying out of the building in which the Northern Counties Fat Cattle Society held its exhibitions," F. Newburn, jun., Esq., introduced the following suggestion:—"This year our clashing with Birmingham has been sadly detrimental. I have always said, and maintain, that this country for such displays of fat stock and poultry is divided into three centres. London for the south, Birmingham for the midland, and Darlington for the northern counties. It is absurd to say, let us be independent of everybody—we can't. If we hold meetings when our exhibitors cannot appear at Birmingham, we do them injustice and ourselves harm. But if we avoid Birmingham, well and good; and if we steer clear both of it and Smithfield, so much the better."

We consider that suggestion deserving of the most favourable attention of the Committees of the three Societies, for it would be conducive to the interests both of those Societies and exhibitors if they were held by previous agreement at intervals of three or four days during the first half of December. It would enable more exhibitors to be at each, and it would give the exhibitors chances of obtaining more prizes.

At the dinner of the Northern Counties Society, Mr. Newburn remarked upon a rather novel point from which to view the benefits derived from such Exhibitions. He said:—

"If they took the aggregate number of animals shown, they found there were about 200 cattle, sheep, and pigs, and the aggregate number of birds shown was 1104. They might say, and very fairly, that it was all nonsense talking about eating

such birds, and he should cry with them, 'hold hard,' because, not only the birds would be an extremely expensive dish, but it would be a downright sin to kill such very beautiful specimens. But to produce any single object of competition they must have at least ten to choose from. He addressed agriculturists, and believed they would tell him that average was too low—he knew, in poultry and pigeons, it was under the mark. But let it stand. Therefore, if they multiplied 1304 by 10, it had actually taken 13,040 animals to produce that show. That was one of the reasons why a display of the feathered tribe and fat stock was of immense use, owing to the number of drafts that must be taken from the herd, the flock, the pigs, and collections of poultry, to improve the general market for consumable food."

FATTENING GESE QUICKLY AND CHEAPLY.

A FRIEND informs me that his Geese have fattened in much less time than heretofore, by feeding them on pulped mangold with a good sprinkling of barleymeal. I have ordered my bailiff to try it (although hardly a fair trial, as the Geese have "been up" some time) and will, if you wish, inform you of the result. I should like to know if any of your readers have tried it. Bentall's pulper is the one used.—C. T. H., Dorset.

POULTRY FOOD AND LAYING HENS.

SEEING many of your young correspondents inquiring respecting food for poultry, especially for laying hens, perhaps the following information may be of some use to young fanciers. I have tried many different sorts of food, but none I think so favourable for plumage, condition, and egg-producing combined, as the following.

In early morning I feed upon warm mashed potatoes and crushed oats, and each alternate day at noon with whole barley and oats. Every night I give a warm mash of barleymeal, fine bran, and crushed oats, always having plenty of fresh clean water given twice a day, especially when the birds are shut up in pens, and I turn them out two or three hours every other day to have a run amongst the grass.

My stock consists of Spanish, Cochins (Buff and Partridge), Game, and Dorkings, and a few common hens for nurses.

Since I fed on the above-mentioned food, I find my fowls eat less and lay better, and are in much better plumage and condition than when fed on whole grain.

My pullets (Cochin, Spanish, and Dorking), have been laying for the last two months and upwards. My Cochins hens of two or three years of age have been laying, some a month and some a fortnight ago. I have not one out of ten old birds that has not laid upwards of a fortnight. My three-year-old Dorking Game and Hamburg hens, are also laying. I may also mention that I feed entirely on this food, both exhibition and general stock fowls, and, I may add, I have not had one sickly bird this year.—FANCYER.

SOLUTION OF THE "SUPER-POSING" PROBLEM.

IN the following letter, that excellent apiarist "B. & W." not only hits off the super-posing difficulty with his usual ability, but so completely reconciles the apparent discrepancy between the results of my own experience and that of my courteous opponent, Mr. John Brown, that I have not the slightest hesitation in giving my unqualified assent to the conclusion at which he has arrived.—A DEVONSHIRE BEE-KEEPER.

"My own experience in the super-posing of hives in the manner in question is simply nil. But, if I had been asked my opinion and advice by "A. W.," I should certainly have given it almost in your very words, judging from my experience of the way in which bees desert supers and glasses full of honey, provided the main hive be well supplied. I have no hesitation in saying that in the ordinary practice of the stoving system, as taught by Dr. Bryan or modified by every apiarist of my acquaintance, including yourself, bees would not ascend into the super-posed hive provided the lower one were tolerably well-filled with sealed honeycomb. At the same time, I am equally of opinion that in bar-hives, if the top board of the lower hive were removed and the bees were allowed an uninterrupted

passage upwards from every comb, the bees would ascend and make the super-posed hive their winter quarters carrying up with them by degrees all the honey stored below; and this even were every external aperture closed save the entrance to the lower hive. In my own case I never have removed the top board, and therefore I have invariably found the bees, after a time, descend to and remain in the lower hive, both in cases where I have super-added brood and bees from other hives in greater or less quantities, or when the bees have themselves occupied and laid up stores in a super. If I read the statement correctly, at page 78, I infer that in the north, when they super-pose, they allow the bees a free passage upwards from every comb, which can only be by removing the top-board."

If this be so, all this disturbance has been about nothing. The northern practice makes of two hives but one; our southern practice leaves the hives two; and so "A RENFREWISH BEE-KEEPER" is speaking of one thing and you of a totally different and distinct matter. Therefore, guided by our present knowledge, arising out of this recent correspondence, I should give to "A. W." this better advice—to follow the northern plan if he wished his bees to take possession of the upper hive, and your advice if he wished the bees to descend. In thus saying, while I seem to side with the former, it is only in regard to the better plan for effecting "A. W.'s" purpose. I am not the less of opinion with you that our southern mode of procedure would terminate as you have indicated in your remarks in page 38.—B. & W.

LIGURIAN BEES—EARLY BREEDING.

SATURDAY the 7th inst., being warm and fine, I took advantage of it to shift into a dry box a stock of Ligurians which I had previously remarked as suffering from an excess of moisture during the severe weather of November. On emptying the hive, however, I found that I might have spared my labour, as far as dampness was concerned; the box being perfectly dry, although discoloured by the recent presence of internal moisture.

Whilst transferring the combs and bees, I, as a matter of course, sought an interview with her majesty, whom I was pleased to find in apparently excellent health. I was also more than pleased at discovering that breeding had fairly commenced; some hundreds of eggs having been deposited in one of the combs. It may be remembered that during the severest cold of last January, I found a mass of sealed brood in a comb which fell out of an Italian stock. These circumstances appear to prove that whilst Ligurian bees (like the common species) cease breeding in October, egg-laying recommences with them early in December, and is continued during the winter. I have reason to believe that breeding is now pretty general amongst all my stocks; but as I have no black bees to compare them with, I should be glad if any of the apiarist readers of THE JOURNAL OF HORTICULTURE, who possess facilities for making such observations, would kindly state if egg-laying has yet commenced amongst their black bees. That the Ligurians possess a decided superiority in this respect is the present opinion of—A DEVONSHIRE BEE-KEEPER.

IRREGULAR PRODUCTION OF DRONES.

I HAVE often thought that the following incident that occurred in my apiary in the year 1859 was rather singular. I send you the account of it, and if it is worth a place in your Journal you can publish it.

On the night of the 16th of January, 1859, a wooden house containing two straw hives, prime swarms of the previous summer, was blown over on its roof in a gale of wind—a pleasant sight on looking out of one's bedroom window the first thing in the morning. You may be sure I dressed quickly. When I opened the door, which I was enabled to do with the house still on its roof, a melancholy sight presented itself—both hives upside down, one with the combs very much damaged. I threw a tablecloth over it and brought it into the house. The day proved fine and sunny. I placed the hive on a chair in an unfurnished room facing south.

I fortunately had a wooden hive with a window in it, about half filled with new empty combs, only worker-comb. I placed this hive in the window on a shelf wedged up, and put some

* O. withdrawing all the slides in hives, of the Stevenson construction.
—A DEVONSHIRE BEE-KEEPER.

honey under. I then uncovered the hive—numbers of the bees flew to the window. I cut out the damaged combs, handed them to my sister who swept them off with a feather into the window. At last I found the queen, placed her under the hive, and in a short time all the bees settled on the combs, and a pleased hum was the result.

I kept this hive in the sitting-room, feeding the bees under a bell-glass at the top of the hive, taking them to the garden every fine day, removing the zinc at the entrance, and bringing them in at night. I supplied them with pollen out of their own hive, which they refused as soon as they gathered fresh from the flowers. I examined the broken combs, and could not discover a single egg.

Now this hive was upset on the 16th of January. On the 6th of February a dead grub was brought, not a very young one. Now comes the strange part of the story. On the 23rd of the same month, I found a small drone at the entrance of the hive; it was fully developed, alive, but not larger than a worker. I brought it into the house but it soon died. I could not see, on looking through the window of the hive, that any drone-comb had been built. No other premature drones made their appearance. This hive thrives very well the next summer.—J. L.

[The irregular production of drones was noticed by "A DEVONSHIRE BEE-KEEPER" in pages 350 and 431 of our last volume. We are inclined to believe that it takes place more often than is generally supposed. It would appear that the delicate apparatus which regulates the sex of the egg does not invariably fulfil its allotted functions, and hence the occasional deposit of a drone egg in a worker-cell which results in the production of a small drone as described by our correspondent.]

APIARIAN NOTES.

COBSAIR BEES.—Your correspondent "S. B." complains of an attack made by some Ligurian bees on his "black bees." In certain populous localities in Great Britain, there are numerous hordes of mankind who do little or no work, and live upon their richer neighbours. So it is with bees, if a strict watch is not kept upon them. One of the "besetting sins" of our favourites, the black bees, is their vile propensity to plunder, generally, too, the strong against the weak hives. In a large apiary which amounted, at one time, to twenty-six stocks, besides show umb-b-hives, when it was discovered that any one stock of bees had taken to plunder, my plan was to endeavour to watch the flight of the "Cossairs," as Dr. Bevan called them, and if it were discovered in the same apiary to apply the brimstone match to the plunderers, for, as assumed, if bees once take to this mode of increasing their store, they never give it up, like some dogs that have tasted the blood of sheep.

I have known a stock increase in weight, 15 lbs. in one week, by plunder. I have tried various remedies; one removing the plundered hive several hundred yards; another plan, closing the entrance to the plundered hive at night, in the morning the plunderers will be in a busy cluster attempting to get in. Kill them all on the spot, be not afraid of sting, these thieves never sting, because they are not defending their own house, they are arant cowards always when tackled.

It seems evident that the Ligurian bees have the same bad qualities as their black neighbours, and I advise "S. B." never, on any account, to allow any honey or sweets of any kind to ooze out of his bell-glasses or any other part of the boxes or hives, as the bees have an extraordinary instinct of communicating to each other where they can obtain honey. In the autumn and spring these attacks are the most frequent.

The entrances of all hives, in spring and autumn, should be contracted as much as possible. I have known bees to fly the distance of 1500 yards to attack a stock, and he must be an acute watcher who can possess a dozen stocks of bees through bad seasons, without having suffered from this; the greatest vigilance is required to prevent it, for it is part of their nature whether the brood-combs are above or below.

SCALE-POSED HIVE.—I agree with Mr. Fox that the top hive does not become the stock-hive. I have had many of Nutt's hives in former days, and have always found the bottom hive the stock-hive after several years remaining double, still, there may be exceptions, but I believe very few to this rule.

DRIVING BEES.—I candidly confess that I never had any success in driving bees, and I agree with Mr. Nutt on this point,

that it seldom answers. How your correspondent "ALPHA" can induce the whole of his bees to leave an inverted full hive, even when the hive rests on the sides of a metal pot, I cannot conceive. I have always found be most difficult to drive from their brood-combs, to which they are more attached than to those full of honey. Mr. Nutt, who was certainly a good manager, although now considered of-fashioned, tried driving until he gave it up altogether in disgust. The irritant or prod of is excessive, and renders the bees quite furious even in driving in the usual way, with the full hive placed evenly under the empty one.—H. W. NEWMAN, *Hillside, Cheltenham.*

COOKING DIOSCOREA BATTATAS.—Wash, but do not peel the Yam; put it in cold water and boil till tender. Scrape off the outer skin and cut lengthways in thin slices. Fry of a pale brown, in eggs and crumbs of bread. Send to table dry and crisp.

OUR LETTER BOX.

FOWLS IN A COMMON YARD (E. P.).—If you feed them regularly in their own roosting-place, they will soon know their own. No confinement will cure cocks having the propensity to fight. You had better let your fowls out, and let the rivals fight it out; if you cannot divide the yard between yourself and neighbours, cannot you have a fenced partition?

STRUTTS OR LIONS' ONE-TOO WASH FOR PROFITABLE FOWLS.—You do not state the nature of the run your fowls have. I should be wholly, or at least partly, grass. We believe Cochins and B. almas to be the best winter layers, but with them as with everything else, it is a question of age. It is quite impossible to state any quantity of food as sufficient for a yard of fowls. If they are taken to what they are doing, they eat twice as much when they are improving as they will when they are well in condition. No particular weight of food should be given at a time, but just so much as the birds can eat, and no more. The food should be ground oats mixed with water. They should be fed with this morning and evening, as much each time as they will eat readily—that is, run after. The food is so mixed, and the fowls are badly fed when any of the former lies on the ground, or when they can get it at any time. The two meals we have spoken of are enough if in the middle of the day they have some whole barley thrown to them and scattered about. The five cocksters are enough, if you want only eggs; but if you have any idea of hatching they are neither odd nor numerous enough. For sixty hens and pull-t in January you should have eight cocks, and they should be nine months old. If one or two are adults so much the better. The pullets are profitable layers, their eggs are numerous, and very large. They are not lay till they are nine months old. Cochins and Brahmans lay at six, and often before. If your fowls are confined, and cannot get at green food, it must be supplied to them by hand. They must also have dust, gravel, and lime at hand. It has been a bad time for eggs, but the pullets are now beginning to lay.

CLEANING WHITE COCKINS' FEATHERS (A Subscriber).—Wash them with water and common yellow soap. When clean wipe them as dry as you can, put them in a basket with some clean, soft straw, and put them before a fire till dry. Soda cleans the plumage, but it sometime injures it.

PRIZE GAME BANTAM AT BIRMINGHAM (J. A.).—We do not know.

MAKING A DORRING COCK'S COMB ERECT—INDIAN COCK (P. H.).—If you fasten the comb with silver wire in the position you wish it to retain, it will do so, especially as the birds are young. An ear of corn or meal makes birds very fat, but the fat does not stand against cooking, and the lean is both hard and bad-flavoured.

AGE OF BIRDS IN A CLASS FOR COCK AND TWO HENS (Idem).—You can show any ages you please, and different ages in the same pen, no class which simply offers a prize for the best cock and two hens shows. The words simply imply sex, and have nothing to do with age. We do not think you will find customers for your Poules de Heche at a very high price. They are little known in England. The best plan is to advertise them in our columns.

POINTS IN SILVER-SPANGLED TAMBOUR COCK (H. C.).—A silver defects and spangled breast are both essential in the form of a Silver-spangled Hamburg cock. No amount of merit in the wings, neck, or alone for the absence of the other. Yet if we had to choose absolutely between two, and the ear-love of the bird with the good breast was only faintly, but absolutely red, we would take it in preference to the back break. It is essential in the gold, and essential that the hackle and saddle be clouded, but it is not the case with Silvers.

RABBIT SELLING (J. D.).—The case you state is clearly within the jurisdiction of a County Court. You must sue the purchaser in the court of the county in which he resides.

LONDON MARKETS.—DECEMBER 16.

POULTRY.

There is but a sorry trade, and we do not anticipate any alteration till we come into the Christmas market.

METEOROLOGICAL OF THE WEEK.—At Chiswick, from observations during the last thirty-four years, the average highest and lowest temperatures of these days are 43.3° and 31.2° respectively. The greatest heat, 58°, occurred on the 28th in 1835; and the lowest cold, 8°, on the 28th in 1853. During the period 141 days were fine, and on 97 rain fell.

GENEALOGY OF VARIOUS GERANIUMS.

WRITING in a hurry,

I made a marvellous mistake last week, at

page 237, where it is said, "We are not aware of any hybrid Geranium being now in cultivation. They are all cross-bred plants, the offspring of one original kind." They are nothing of the kind. It is quite true they are all cross-bred plants and not hybrids; but as I have not yet given my own

opinion on Mr. Darwin's theory of the origin of species, my saying our bedding and show Geraniums "are the offspring of one original kind" is wrong altogether, and at the very opposite of what my practice would point to. All the Ivy-leaves are, undoubtedly, the offspring of one kind. All the Scarletts are, without doubt, the offspring of one kind also; but whether that kind was a plain-leaved one like Tom Thumb, or had the horseshoe mark, there is no evidence to prove either way. The Geraniums of the florists in my early days, were the offspring of half-a-dozen kinds, but since then they have been brought down to the breed of *Cuculatum* alone. The bedding Geraniums of the greenhouse class, as Lady Mary Fox, Unique, Sidonia, Ignescens, Touchstone, and all the rest of them, are all hybrids, or the immediate offspring of hybrids—that is, from the union of two distinct members of the Geranium family. And it was from the early union of such distinct kinds that the botanists of the last generation took up their wrong ideas on muling or muled plants. All that you can find in all the writings of all botanists about muling is altogether wrong, and I question very much if there is such a thing on the face of the whole earth as a mule plant.

But let us go straight according to the heads laid down. The first was the Ivy-leaf. No other kind ever crossed with them, and few as their number is, there are more botanical mules among them than are to be found in any other section. A botanist will tell you a mule is a barren cross between two distinct kinds or species, and he will give you a reason why it is a mule, after such a fashion as this: That the parents stood in such and such relationship to each other. But in those days the practice of cross-breeding did not begin at all, the whole thing was confined to hybridising. But so soon as cross-breeding began, it spread like wildfire, and the results from it soon proved that some of the deductions of the hybridisers were altogether untenable.

Muling was one of these deductions, or hypotheses, and is untenable also, for the cross-breeder will give you twenty mules and fifteen seedlings which are not mules, from one pod of seed which was fertilised by the pollen of the same flower: thousands can do it. Then, if a thousand cross-breeders can but produce each by his art one mule from one plant only, can you suppose such a thing as that Nature herself would require two kinds of plants to enable her to originate a mule plant between them? If you can believe such a doctrine, stick to your

text, for it would be as a thousand cross-grains to one to disturb so harmless an idea.

The next are the Scarletts. Are they all really from one kind? I think they are, for this reason, that the plain-leaf and the horseshoe-leaf are convertible the one for the other at every change in the pollen. Botanically I may be wrong, and the horseshoe may have branched off from the "Cape Scarlet," ages before the Cape was known on this side of the line. Both the originals are lost, but a cross-breeder could reproduce them in one season. The Golden Chain is an immediate sport from the "Cape Scarlet," of my boyish days, the *inquians* of botany, and true seedlings of the sport will furnish the type plant among them certainly.

The original Horseshoe Geranium from the Cape was a true Nosegay, according to Miller who first described it popularly in English. In his time "it was the oldest and the most common sort in the English gardens," and attained to one-half only of the size and stature of the plain-leaved Cape Scarlet. According to him the flowers were "of a purplish-red colour." I put the italics because many people believe the original horseshoe-leaved kind had the same tint of scarlet as the *inquians*, and being not of the same colour as the original plain-leaved Scarlet fortifies my belief in its being only a wild sport. The tints of all the sports of Geraniums are different from those or that in the parent flower.

The next sport from the same plant was under cultivation, and it was the Golden Chain, the style of flower much the same as in the first sport, the Horseshoe, but the leaf and stature widely different, yet in one sense a real Horseshoe after all. Then we know very well that the first horseshoe-leaved Geranium was not a "fixed" kind as late as Miller's time—that is, not a true botanical species, for it would not then come true from seed, or, at all events, the seedlings would not be all like the parent, as they ought to have been if the parent had been a true wild species. Miller distinctly says there were four varieties from it under cultivation round London in his day, "one with fine variegated leaves, one with crimson, and another with pink-coloured flowers which have been accidentally raised from seeds," the fourth being nearest the original. Now, do you know of any really botanical species which would not come true from seeds the moment it was in cultivation? I never knew of any such species: therefore, I believe the Horseshoe Geranium was never a species at all, but a sport; and, therefore, also, I say and maintain that all the Scarlet Geraniums which are now in cultivation are referable to one original kind. And when a man tells me he had been hybridising his Scarlet Geraniums, I know very well that he could not have been doing any such thing—that he was merely cross-breeding the seedlings of one kind, as I believe them to be, and as I have attempted to trace and describe them. There was a large bed of the original Variegated Geranium mentioned by Miller, as a seedling sport from the first Horseshoe Geranium on the Rose Mount at the Crystal Palace last summer. Seedlings from that variegated sport will give, among others, the identical

first kind of Horseshoe on record, just as the Golden Chain will reproduce the original Cape Scarlet, or inquilans, such as Linnaeus described them in his "Hortus Upsalensis."

Then, it is evident that we improve the different sections or races of the family of Geraniums by a process the reverse of that by which the breeds of horses, sheep, and cattle are improved—that is to say, by breeding in-and-in, or cross-breeding, which is entirely and altogether different in its effects from that of hybridising; and if we would attend to these practical differences, as between cross-breeding and hybridising, it would greatly tend to simplify our meaning, and to instruct our readers in the practical application of the same process. But it would not be to simplify our meaning just yet awhile to give a true definition to another turn of the process of applying the pollen—I mean when we cross a distinct wild species by one, or with the pollen of one, of our cross-bred seedlings. Thus, when I said "if the green parent of Mangles' Variegated Geranium would cross with Tom Thumb, or with any other bedding Geranium, the seedlings would be hybrids," I was not strictly within the law. Tom Thumb is not a true species like the other, but a cross-bred plant; therefore, the seedlings between it and the green of Mangles', which is a genuine wild kind, would only be half hybrids; but it is hardly worth while to introduce so strict a definition of our practice. Mr. Banks' seedling Fuchsias are all cross-bred plants, not hybrids. When one of them is crossed with Fuchsia serratifolia, a wildling, the seedlings, strictly speaking, would neither be hybrids nor cross-bred plants—only half hybrids. But that fine, large, winter-flowering Fuchsia from the Messrs. Veitch, called *Dominiana*, is a true hybrid, because it was got by crossing two distinct wild kinds of Fuchsia. So we are not left to the fickle fancy that breeding in-and-in can alone improve our seedlings.

Hybridising is the only means given to us by Nature to obtain new races of plants, and by cross-breeding alone can we still further improve all new races. When Nature gives us more than one race in a family, as in these Geraniums and Fuchsias, and we despise them all but one, as florists do in Pelargoniums, and in turned-in-floret kinds of Chrysanthemums, we do not respond to the kindness of Nature for the gratification of our senses. Barring this clause, I would be a florist, and always was, and I hope to continue to be so to the end of the chapter. But the care and kindness of Heaven in supplying us with so many sources of innocent enjoyment I should be the last on earth to ignore in one single instance; therefore, I have very great pleasure in telling you a tale.

I have just made out one other new kind of Miller's old sporting Horseshoe Geranium. He said that kind sported from seeds, and from a "reddish-purple" flower turned to a "crimson flower," and to a "pink flower." Now, did you ever see a real pink Geranium of the Scarlet breed? I never did or heard of such a thing but in Miller's. When I had to pay the strictest attention to all the distinct colours and shades of colours for the flower-beds under authority, there was no pink Geranium such as Miller speaks of, save the little, close-growing, pink, Ivy-leaved Geranium; not another like it, or in the likeness of a true pink colour could be had among all the Geraniums. All their pinks were tinged with rose or with cherry colour. Miller was too good a judge, and too practical a gardener to call *carise* a pink, or a *Lucia rosea* the same; but he says a pink Geranium of the Horseshoe class was common in his days—that is, say one hundred years back, and I told you already the influence I had over the stamens, but never said a word about the ways I exerted that influence from 1853 to last season, in endeavouring to hunt out from the horns of the pistil this same pink of Miller's, or one in the same degree as he would call pink. I found it, and I shall leave it as a legacy to the ladies.

By another mixture of the same strain, and with an utter abhorrence at the apocryphal doctrine of superfetation, I found at the same time a real true and pure magenta colour, the very finest tint we have in all the race. I do not yet know what names these will bear, or how they will be sold, but they are in the hands of my agents. My present mark, however, is on what Mr. Smith has done and lost between the Golden Chain and Mangles' Variegated Geranium with the shorter stamens. I think I offered 5s. in these pages to any one for one seed of Mangles' some years since; at all events the offer was on my tongue for two or three years after I left Strubland Park, where I once had a chance truss of seeds on Mangles' with five or six seed-pods, so to speak, and every one in the garden was cautioned not to go near it, which was the surest way to make every one

itch to be at it. Sure enough some one cut it off ere it was half ripe, and I never saw a man so near cutting off his own head as Mr. Wells was well nigh doing when he, then foreman of the department, found it was gone.

Then about the 5s. A lady once took me at my word—the lady of Capt. Whitty, now inspector of prisons in Dublin—the lady who manages the Waltonian Casa so well that Mr. Fish must have called on her on purpose for a leaf out of her book. Mrs. Capt. Whitty assured me she had often sowed Mangles' Variegated, and would do so for me that season, and she was as good as a man to her word. She ripened two seeds that summer (10s. hard cash), but I was ungallant enough to resolve not to pay till I found the seeds had sprouted, which they never did; but whether that was to save my money or my credit as a gardener, I leave you to judge, and shall go any lengths to persuade other people to try the effects of the shorter stamens of my new pink Geranium and my real magenta on a two or three-year-old plant of Mangles', for Mangles' and the green type whence it came are true pinks so far, only pale pinks, yet free from the slightest tinge of rose or cherry colour. Then, if they, or any one of them, succeed in seedlings, we shall possess materials for a new section of pink, real pink Geraniums; and when we plant equal quantities of pink, purple, crimson, scarlet, and yellow, and learn to put the colours in the right positions, our flower gardens will be something more than a blaze of scarlet and yellow.

D. BEATON.

VISITS TO SOME OF THE FRENCH NURSERIES.

(Continued from page 213.)

MONSIEUR MARGOTTIN, BOURG LA REINE, NEAR PARIS.

THE name of this most successful Rose grower is well and honorably known in England as the raiser from time to time of some of our most sterling Roses. Louise Odier, Jules Margottin, and Belle de Bourg-la-Reine are sufficient to stamp the character of any one who has been fortunate enough to introduce them to the public as a man of note, and one whose opinion on the merits of the flower which forms his *spécialité* is well worth considering. All the anticipations I had formed concerning him were thoroughly borne out; and I have little hesitation in regarding him as the most thoroughly practical Rose grower I met with in France, and also as an upright and honest man. Of this I feel perfectly convinced—that however he may be mistaken, as must unavoidably be the case with everybody at times, he will never send out a Rose which he believes to be below par; and he, more than any Rose grower I met with in France, seemed to appreciate shape and constitution as so very desirable. A notice, then, of his nursery I cannot but hope may be interesting to those who, like myself, loyally regard the Rose as the queen of flowers.

On the short line of railroad which runs from Paris to Seaux there lies the suburban village of Bourg la Reine, and in the main street of the village Monsieur Margottin resides. His nursery runs at the back between the street and the railway, and is in a more cool and sheltered position than most of the nurseries about Paris. The soil being, moreover, that unctuous loam so dear to Rose growers, and not unlike the Hertfordshire Rose grounds; and as it is almost entirely devoted to the Rose, and especially to the raising of seedlings, it could not but be that great interest would attach itself in my eyes to such a spot. At that late season (Oct 10th) it was not, of course, to be expected that we should see much in bloom; but we did see in every part of the ground grafted, budded, and on its own roots, *La Boule d'Or*, opening most freely, and one of the yellowest and most beautiful of Tea Roses it is. I have strong hopes, therefore, that notwithstanding the disappointment it has occasioned this season it may by-and-by, even on our side of the Channel, prove a desirable Rose. In colour we have nothing at all approaching it save Persian Yellow.

Of the new Roses of last season, he spoke very highly of Madame Furtado, which I fear, however, will prove to be out an indifferent grower; also of Catherine Guillot (Bourbon), which for shape is not to be surpassed. Reine des Violettes, too, he pronounced good; but then I think those slaty colours are much more according to French than to English taste. General Washington he also considered a valuable Rose, as I have no doubt he shall find it.

His own seedlings of this year were in bloom and promis-

well. *Souvenir de Comte Cavour*, H.P., is very dark, rich deep velvety crimson, shaded with black; the petals of great firmness, and the flower tolerably full. *Alexandre Dumas*, H.P., is nearly black, and also seems as if it would be a very desirable Rose; while in *Comtesse d'Ouaroff* we have a strong-growing and erect-flowering *Souvenir d'un Ami*, and therefore likely to be a great acquisition.

That *Monsieur Margottin* exercises a wise discretion in the sending out of his Roses may be gathered from the fact that he grows upwards of 30,000 seedlings, and from these has only selected these three. Of seedling growing he gave me some interesting particulars—thus. He says he had one year from *Louise Odier* about twenty varieties of every colour from white to nearly black; and that, although they looked very promising, not one of them when grafted was worth anything, and were all thrown away. Then, again, he stated that seedlings, if they flourished either the first or second year, were generally failures. Their constitution was so bad that they died off the third year, and several gaps were shown to us where such had been the case; while a seedling that does not flower until the fifth or sixth year was generally likely to be good, it being generally the case that those which flowered little and grew well as seedlings would, when grafted or budded, flower better.

The season of last year, which proved so fatal to us, was well nigh as damaging near Paris; and *Monsieur Margottin* showed us that not one of the seeds which he sowed last year had made its appearance, and this although apparently it looked well—thus manifesting that there was the same want of vitality there as here. Again, on the subject of the Moss Rose, about which so many pretty conceits have been by poets invented, and sung by lovesick youths and maidens. He stated that although he only saved seed from Hybrid Perpetual Roses and had no Moss Roses in his garden, that yet out of every ten or twelve thousand seedlings he was pretty sure to get one or two Moss Roses, and he had then one Perpetual Moss of which he hoped good things. There were some seedlings, too, from *Louise Odier*, which promised to be of some note, and they will be probably introduced to the notice of the public next year. Rose exhibitions are not much patronised in France, the greatest interest being taken in seedlings, which as a matter of course pay better, and hence the general stock of Roses is not as large as one might expect.

I cannot but think that the commercial point of view is the one from which the value and importance of the Rose is most regarded by our French friends. Here will be, perhaps, the proper place to say that, feeling this, I was extremely desirous of trying to induce the French growers to come over here with their seedlings next year, when everybody will be on the wing to the Great Exhibition. I mentioned it to several friends; and my plan was, that twenty of us who were interested in the growth of the Rose should subscribe a guinea each, and offer it in three or four prizes to the best six blooms of any one Rose which was not as yet for sale. I put myself into communication with the Council of the Royal Horticultural Society in order to see if they would sanction its being part of their plans (as Mr. Wentworth Dilke's prize was), for the ensuing year, feeling that that body was best known in France. The offer was accepted; but as I was only given one week to complete the arrangements, which would have been quite inadequate, I was compelled to give it up. I cannot but think the scheme practicable. London is reached from Paris in ten hours and a half; so that Roses cut the night before might very well be at Kensington Gore by eleven o'clock, and by giving additional liberty to such exhibitors, would be in abundance of time.

The same kind and genial hospitality which we experienced at other places was shown to us by *Monsieur Margottin*, who has some good knowledge of England, as his son was for some time at Mr. Paul's, of Cheshunt. A more complete knowledge of Rose-growing it would be almost impossible to meet with than he possesses, and, as I have said, although he may be sometimes mistaken, I should be quite ready to take his opinion on all matters connected with the radiant queen of flowers. He grows the *Hollyhock* too, which he told us was another Rose, and is indeed so called by the French—*Rose tremière*, or *Passe Rose*! and of these he had some of the best English and Scotch varieties. He had also some *Camellias* and other flowers, but the Rose was his chief concern; and I can only express my hope that he may long give it his attention, and gladden the eyes of our English rosarians with some worthy competitors of *Jules Margottin* & Co.—*D., Deal.*

CUTTING DOWN CLIMBING ROSES.

In your Number of December 10th, I find in your answer to "B. B.," you recommend that climbing Roses should be cut down to within a foot of the ground the first season, and for other two seasons also. My house is a very high one (five stories), on the edge of the west cliff of Whitley, and immediately facing the German Ocean, from whence we have most severe gales of wind. The front of the house is exactly east; there is an area 8 feet deep, or below the ground, and 6 feet wide. The sun only reaches the bottom of the area in summer for an hour about 10 o'clock in the morning. To grow up the front from out of this area I have planted two Rose trees, one of which has now grown 10 feet high, the other is still only about 2 feet, the same as when it came. I want to know if I have understood your meaning right, and that I must cut down my beautiful trained tree, if it is too late, and would spring do? I should also feel obliged if you would give me the names of some other sorts of climbers that would look well and flower in July, August, or September, and be very hardy.—S. B.

[Under the circumstances you ought to cut down both your climbing Roses to the very surface of the ground next March, and the more you cut them the next March and the third March the sooner they will cover the wall, although that sounds odd. But if your climbers were Cloth of Gold or Isabella Gray, or any other Rose as shy of blooming as they are, they should not be pruned at all till they were so exhausted as to bloom freely. All climbers soon exhaust themselves if they are not pruned, and the free bloomers will soon cease to be so if they once become exhausted. The parts next the ground get so hide-bound that nothing will save or refresh them but a cutting down to the last joint, and better do that first than last. The next best climbers for you are *Clematis flammula*, and *Vitellia flammula*, and the common *Traveller's Joy*, *Clematis vitalba*.]

THE IN-DOOR PLANT CASE.—No. 5.

(Continued from page 200.)

GREENHOUSE FLOWERS.

I HAVE NOW to describe the most suitable arrangement for a case to be filled entirely with greenhouse plants—in summer, of course, for these no heat is required. In winter, however, those that have had most forcing, and even hardy plants forced into early blossom, do best at the warmer end.

In filling a greenhouse-case the first thing to consider is which plants to place the nearest to the light, and which will bear to touch the glass without injury. Very juicy crisp sort of leaves in general, like Primroses and Geraniums, suffer very much from the slightest contact. Thicker and more leathery-textured evergreens will, however, be quite uninjured; and these may, therefore, be placed at either end.

I find *Myrtles* amongst the very best and pleasantest plants for giving this dark foliage; but then I am fond of growing plants from which one may sometimes gather sprays of green leaves and flowers, and *Myrtles* seem quite wonderfully to submit to such pruning. A good arrangement is to place a large *Myrtle* in each corner, and then to let a *Camellia* spread itself out in front of it.

The large-leaved flowering *Myrtle* is one of the nicest; but the small-leaved kind is still prettier for cutting, and it looks very charming when not allowed to have too long a stem. *Myrtle* cuttings strike more easily in these cases in a little sand than in any way that I know. The old plants require a great deal of water; and this deserves attention, since if it be not given they are apt to lose their leaves. In the glass cases dust accumulates with exceeding slowness; but even thus it is well every now and then to refresh the foliage of these thick-leaved plants by washing or sponging. The simple cottage plan of standing the plants outside during a soft mild shower is very beneficial; but in London the rain is not always purifying, and it is always necessary to guard against worms ascending into the pots through the drainage-hole, as they tear the roots and inflict much injury. I

have known great masses of roots completely separated from the plant by this very thing. Camellias are most useful plants, because they have such beautiful and such massive flowers. They may also after flowering be stood out so safely under a wall, or even on a house-roof, so that only the pots are sheltered or placed in others. Draining the outside pots with finely pounded ashes is a good means of preventing the entrance of any worms when the plants stand on the ground.

In the glass cases my own mode is never to water Camellias at all. They are very awkward things to water—too much or too little mostly causing the buds to fall; and thus I use the flower-pot as a kind of filter, and content myself almost entirely during the time of flowering with watering the sand that surrounds the flower-pots. This, however, has to be kept pretty moist. The old double white Camellias have never, I think, been surpassed in beauty, nor in ease of culture and freedom of bloom. *Fimbriata alba* is also a lovely sort.

Crimson and pink Camellias are also most attractive; and for cases I have sometimes had little plants not more than a foot high, which look extremely pretty.

The Camellias greatly enjoy having their leaves kept clean; but I confess to avoiding sponging while the buds are swelling, as on one occasion some years ago all the buds fell off after such a process. I do not know what caused it, but I had a theory at the time that it might have been caused by over-rapid and violent absorption of the moisture.

The Myrtles being arranged at the ends and corners, and duly faced with Camellias, Azaleas will answer most delightfully in the centre, blossoming for an extraordinary length of time and preserving their foliage in a thorough state of freshness. I think the old *Indica alba*, the *White Perfection* (which is a special beauty), *Etoile de Gand* and the *Bride* are amongst the very best of the white Azaleas. The latter, however, I do not think I have ever kept in a plant-case, though it will doubtless answer there as well as any sort.

Rosy Circle and Model are beautiful pink flowers spotted with scarlet rose colour. *Variegata* is a beautiful salmon rose edged or streaked with white; and *Exquisita* is violet pink and white, lovely as its name implies, but not so good as pure white or rose for candle-light.

I generally find the Azaleas do best with a little water daily, or moistened sand surrounding them keeps them very safe. These plants trained down flatly look very well spreading out in the plant-cases below the Camellias, one at least at each end. Those most out should be kept at the coolest side.

Gardenias and Lilies of the Valley should always be coming on, the latter at least from November till April. They do at first with but little light; latterly they require to stand near the window, that they may not grow up too tall.

I do not find Violets answer so well as most things. Perhaps that is, however, because I have been used to such quantities out of doors almost all the year, that I have never till lately tried to grow them much in rooms or in plant-cases.

Roses also seem to require a special treatment, involving a good deal of air when attainable. I fancy that a plant-case kept very light, and filled entirely with Roses, *Mignonette*, and Violets, would answer very well with sand kept a little moist, the front panel out, and hot water given only in the morning; the front panel being closed, or a woollen cloth hung over on a real cold night.

The Chinese Primroses, again, are amongst the most useful flowers. In these greenhouse groups they go on flowering with the utmost luxuriance and beauty. Leaves and flowers both look fresh and beautiful, and they continue for months opening out their large white or lilac or pink-fringed flowers. The single kinds do best at the

cooler, the beautiful double ones at the warmer end. Mine do admirably under the shade of the Camellias. These plants require rather more water than many others; but they should not have much; and if they never generally dry, moist sand outside generally keeps them safe. Almost any plant, if it does accidentally get too dry, requires a good watering as the roots make a tight ball in the middle through which when once hard and dry water can scarcely penetrate without soaking. I own, however, to preferring, when plants are in blossom, beginning this soaking by means of wet sand, to prevent the too sudden change from a starved condition.

Half the secret of forcing flowers in winter in these cases, as in every other structure, lies in giving them always water that is above the temperature of the soil and atmosphere. The other half, I fancy, chiefly consists in how much light they get.

Sweetbriars are well worthy of a winter place in the greenhouse case. They do best at the warmest end, and do not require a very great deal of light. The lower and dwarfer these plants are the better, as we only want their delicious scent.

A Heath or *Epacris*, a *Dentzia* or an Orange tree, should be in the centre. Heaths especially like to have air all round them.

The *E. hymenalis* is a most useful one for these cases; and also the little round white-flowered one, the name of which I cannot just now remember.

With these Myrtles, Camellias, Azaleas, Primroses, and Heaths for the larger and more conspicuous plants, Sweetbriars, Lilies of the Valley, Ferns and Lycopodiums (the latter chiefly for lining the glass at the side next the room farthest from the bright light and for undergrowth), a most exquisite display of blooming plants may be kept up all winter. They last indeed so long, that I am really tired of having for a third week to report the same white Camellia blossom still fresh, as spotless as when it first came out, and showing every sign of lasting a fourth Tuesday! I have generally gathered my Camellias after about the first three or four days, so this is almost my first experiment as to how long they do last.

I must not omit to say, that though it is a greenhouse group that I now am speaking of, a beautiful *Draena terminalis* would answer well and form a charming centre.

The stillness of the air, which yet is in continual circulation, probably tends to equalise the wants of various plants.

Two inches of the top pane open, sand kept rather moist, a moderate-sized water-can of hot water night and morning, and a daily glance to see and remove any fading flowers or decaying leaves, is all the attention that such a case requires, even at this season.

HEATING A GREENHOUSE AND STOVE.

I HAVE had a greenhouse and stove constructed according to Mr. Benton's plan of a portable greenhouse in your Vol. XXI. The building is span-roofed, and adjoins the east end of my house, partly only, for an angle in the wall makes the remainder about 3 feet distant, and in this space I have placed a boiler, a common cylinder with egg-shaped ends, about 30 inches by 12 inches or 14 inches. Being afraid of the expense of getting men from Dublin or London, a local tradesman put up the hot-water pipes; and though his workmanship is good, yet I am afraid he did not sufficiently understand the principle of heating to give me that command over the heat that I required. I want to be sure of 55° in the stove, and 40° in the greenhouse, in the coldest nights. I have managed pretty well so far, but during the frost we had three weeks ago the thermometer went down to 52° and 35°, so I dread the commencement of any such frost as we had last December. To be ready for such an emergency, I have since placed a slow-combustion stove in the greenhouse, with a pipe out of the roof, but I do not like the trouble and dirt of two fires, though I hope by this means to manage for the

present. Through having three separate connections with the boiler, and being on so many different levels, the pipes do not heat evenly. The three-inch pipe is only used during frost, and, perhaps, from being the longest, it robs the others, though on the lowest level of the whole. I might run a second row over it, but then I fear I should not have heat enough in the stove. Could I gain more heat in the latter by carrying the boiler-flue through it, though this would be difficult, as the pipes at present run? Another suggestion made to me, is to place a sheet-iron upright cylinder, 4 feet by 11 inches, in connection with the pipes in the stove at the end of the path near the boiler, and that this will hold a large body of warm water, and radiate a great amount of heat without soon cooling.—AN ANXIOUS AMATEUR.

[Such a boiler, for anything we can see, ought to heat such a house; but yet we cannot see the way clearly how to help you, as we do not know how you have formed your three separate connections with the boiler, nor the relative height of the different pipes in the different places. A cross section showing how much the boiler was below the ground level, and how much the other pipes were above or below it, would have enabled us to see where the error lay, if error there be. As it is at present, we can safely say that for such a span-roofed stove you have not a bit more piping than you ought to have in the stove, and not enough if the temperature requires to be kept high in severe weather. Running the flue, therefore, through the bed and back again, would no doubt be an advantage. For the greenhouse you would have required two four-inch pipes all round. In severe weather you will need the stove before this can be done. It would appear that this house heats best, apt to rob the others, and yet was so low; and yet if the pipes are here the lowest, we should expect that the heating power was also the lowest. We get also confused about the flow-pipe on the one side of the stove being a combination of the return-pipe on the other side of the stove, and not a word is said of open cisterns or air-pipes at any of these bends. It is just possible that a few air-pipes would remedy what you find wrong. If we saw our way clearly we would be most glad to oblige you; but it may so happen that everything is right except the quantity of piping. Even the pipes in the pit we know nothing of as to their position. We may just add, that the reservoir of water will, of course, add to the amount of heat, and that it would be as well to place open rubble over the pipes before adding a foot or 15 inches of cocoa-nut fibre or tan, &c. We may just remind you, which, of course, from your reading you are conversant with, that the top of the boiler should be lower than any pipe; that in close pipes the water should rise in the flow to the extremity, and have an air-pipe there, and return gradually to the boiler; and that if the pipes were lower in one house than the other, and that house the farthest off, but the lowest pipe there still higher than the top of the boiler, then the best way would be to heat all from an open cistern, instead of taking each pipe directly from the boiler—that is, in such a small space as yours, and where no heat at all was wanted, in one and the largest house, except in frosty weather. Keeping in view your present arrangement, then, instead of the large reservoir, we would bring one flow-pipe from the boiler into a cistern at least 3 feet by 1½ foot, and 1½ foot deep, placed at the end of the stove, and three holes in it for pipes besides the flow-pipe from the boiler. A double T-piece fixed in the return would enable you to connect all the returns separately. Then take one flow ending in a T-piece reversed, and you have the flow for both sides of the stove, and the return would go at once to the main return; another flow would go to the pipe inside the pit, the end of that also joining the return, with an air-pipe in the highest bend. The third flow would go along the stove and enter the greenhouse, and there the pipe could go round double, with the return connected with the farthest side, or the flow-pipe could go round, and the return come back underneath it and go on through the stove to the return at the bottom of the boiler. In this case, too, an air-pipe should be inserted in the highest part of the pipe. Each part could thus be heated separately, by moving a plug or a valve at the cistern; and if one pipe was apt to rob the others, the valves or plugs would only need a little regulation to cause the flow to proceed as wanted. The lower any of the pipes descend, provided none below the top of the boiler, the higher in proportion should this open cistern be. We may say, as guess work, that it should be 2 feet or 3 feet above the pipes in the stove, if the pipes in the greenhouse are some 18 inches lower. We hope, however, that more heating power, and the insertion of some

small gas-pipes, as air-pipes, will be all that is wanted. The air-pipes should have the open ends several feet higher than the pipes, and higher than the open cistern.]

DESTROYING AN OLD ORCHARD—WHITE COROLLAED FUCHSIAS.

I HAVE an orchard of about three statute acres in extent. The trees are old; it is about fifty years since they were planted. They are of a bad kind, and very indifferent bearers; and having taken into consideration the expense of a man watching the orchard in summer and other trouble and expense connected with it, I had resolved to root the trees out, and turn the land to agricultural purposes, for which it is well adapted, when I saw a paragraph in your Journal stating that orchards would soon become very valuable, as the Manchester manufacturers had discovered that Apple juice was the best thing now known for fixing the colours in cotton fabrics. Will you let me have your opinion and advice on this subject?

And, to mix the *utile cum dulci*, will you also let me know what are the best of the white corolla Fuchsias, the best time for getting them, and could plants be forwarded by post?—A SUBSCRIBER.

[An old orchard must be tenanted by trees much more decrepid, and producers of much worse fruit than we have ever met with, except in the cider counties, before we should recommend it to be uprooted, and the plough driven over its surface. The probabilities are in favour of the opinion that the orchard is slightly productive, and the scanty produce indifferent, because the trees have been both neglected and ill-used. We should thin out the small branches; lime-wash the stems and main limbs; manure heavily and surface-stir the soil with the fork, and so treat the orchard for two following years. If it showed no improvement after such good care, then let the trees cumber the ground no longer. All animals ought to be excluded from it; no crop grown upon the soil; and no spade allowed to be used upon it.

It is true, very possibly, that Apple juice may be found to be a good mordant, or an aid in some way for dyeing the newly-discovered colours; but if it be so, the malic acid, on which the property probably depends, will soon be manufactured artificially. Scheele formed an acid very nearly like it, if not identical, by treating sugar with fuming nitric acid. The berries of the Mountain Ash and the common House-duck contain a considerable quantity of malic acid, and we hope our textile manufacturers of Manchester will have recourse to all the sources we have pointed out, and leave our Apples alone, or be content with their parings.

Of white corollaed Fuchsias, Empress Eugenie, Mrs. Storey, Princess of Prussia, Queen Victoria, Countess of Burlington, and Eclat are good. Small plants may be had now by book post.]

BORDER BENEATH AN ARBOR VITÆ HEDGE.

ROSE FOR A CHALKY SOIL.

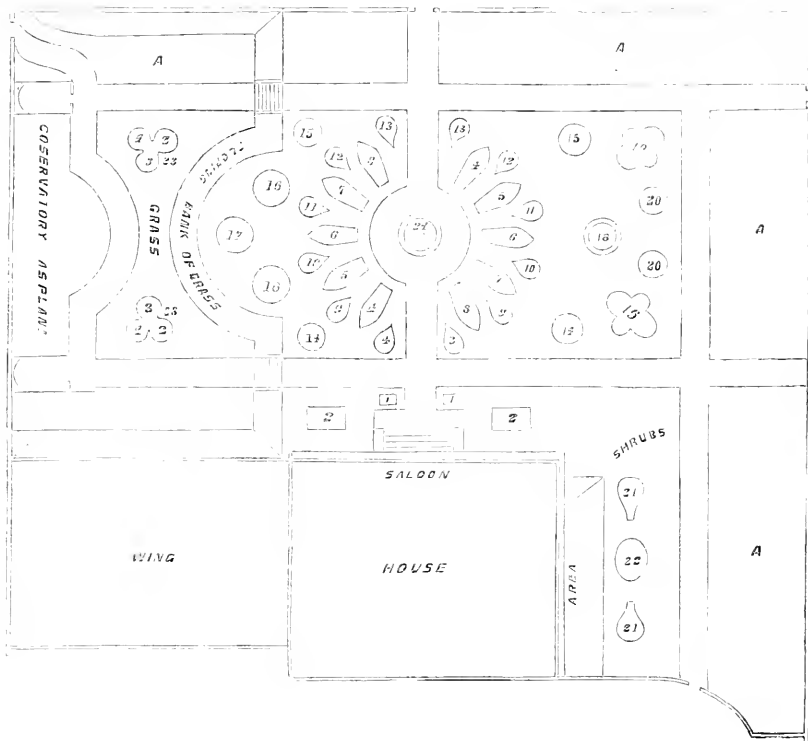

I HAVE a small lawn before my house about 80 square yards. On either side is a hedge of Arbor Vitæ, with a border of about three-quarters of a yard wide. Nothing will grow in this border owing to the roots of the Arbor Vitæ, and I do not know what to do with it. I have thought of doing away with the border by carrying on the turf under the hedge, and another idea has been to sow Mignonette over the whole border.—A SUBSCRIBER AT BATH.

[Turf over the narrow border under the Arbor Vitæ. Mignonette is the very last plant that would grow on a hungry surface, such as your border, sucked by vigorous plants of Arbor Vitæ, on a chalky soil, such as prevails around Bath. When Arbor Vitæ once get hold of a chalky soil they are so much at home that grass or turf over their roots seems to do them no harm whatever, while Roses on that kind of soil only die by inches, unless turf is put over their roots, and then they all go off by the yard measure, except Gloire de Rosémère; but without a chalky soil that Rose, the brightest of the whole race, is not worth looking at. Another of its peculiarities is, that it will not grow well on any kind of stock. While the great peculiarity of all Arbor Vitæ is, that turf does not hurt them if they are on a chalky bottom.]

A FEW DAYS IN IRELAND.—No. 8.

(Continued from page 216.)

LOUGH CREW.

A A A A, Low Shrubs on Grass.

THIS princely demesne of James Lennox William Naper, Esq., is situated in the midst of varied, picturesque scenery in the rich fertile county of Meath, thirty-seven miles from Drogheda, ten from Kells, and two from the town of Old Castle. We were induced to visit this charming place, partly that we might have the pleasure of meeting again our old friend Mr. Milroy, the talented gardener, and partly that we might satisfy ourselves from personal observation of the correctness of all that we had heard of the natural beauties of the place, enhanced by art and design, of the great improvements effected on the estate, and the comforts secured to the labouring population by the benevolent, noble-hearted proprietor, who along with his estimable lady, live almost constantly at Lough Crew, and have uniformly carried out in practice the great principle that "property has its duties as well as its rights." Need we be surprised that such a landlord should be more than respected—should be loved, and next to revered, when his presence must still remind so many that in the dark, gloomy days of famine, passed, we trust, never to return, the claims of right were pretty well forgotten in the anxieties and activities to meet the stern demands of duty? Need we wonder at the prevalence of this feeling of more than respect, when, after the dark days have passed, it is seen that the same untiring watchful, humane vigilance is exercised still, that the happiness of his humble neighbours may be promoted by constant employment, comfortable homes, and suit-

able allotments—thus practically developing a great principle in social economies, that happiness worthy of the name can only be secured when it is based upon, and co-existent with, the comforts and the enjoyments of those by whom we are surrounded? Talk of the might of wealth, and we question not its power, though when not conjoined with felt responsibility it may be a power to blast rather than to bless—a power to repel rather than to attract; but ally it with the twin sisters of benevolence and beneficence, and how great is its elevating influence, how genial its sway! Hard and deeply debased must that heart be that the power of kindness will not soften and ameliorate.

It is sometimes unfortunate to hear a great deal in praise of a place before you see it. Eren Niagara has failed to transport some visitors, because from being previously excited, it did not come up to what they had conceived. We were next to informed we could not pick a fault with Lough Crew, and that, perhaps, just set us on the look out for one, even when surrounded with so much to admire. Our readers must judge for themselves whether we succeeded, or if it is all a matter of imagination.

The position of the mansion is beautiful in the extreme, backed on the east or garden side by a rising glade of turf, and swelling out at the sides to high ground clothed with timber. On the west or entrance front, after a broad terrace of gravel and mown terraces of grass, there is a beautiful valley clothed with the richest verdure, extending onwards to the kitchen

garden, the best part of a mile distant, and far beyond, dotted and grouped with trees somewhat sparingly. On the south side of the valley the ground gradually rises and swells into mounds and hills covered with thriving, well-managed timber, the eye going onwards until it rests on Mullagh Meim and the ruins of Mullough Castle. On the north side after passing over the park, the eye rests on the mountain of Cairn Bawn some 900 feet in height, covered with timber, except bare promontories on the top, showing the bold and craggy rock, and thus throwing a dash of the romantic over the rich picturesque. Other fine

mountains, as Stiene-na-Calliagh and Carrickbreak, are seen a little more distant. Now, from the garden front you see nothing but the distance, and from the garden rising in every direction you can see nothing more. From these facts alone we come to the conclusion that the garden front and the entrance front should be reversed, and the one be substituted for the other.

These are matters for which most likely no one living is now to blame, if blame there is, and, therefore, we may obtain what instruction we can from this fine place without giving any offen-

Fig. 1. Sectional line through terraces, mansion, and flower garden. The line in flower garden broken for room. Line in other places about 60 feet to the inch. Valley falls at A, and glade rises at B.

Fig. 2. Supposed cross line of ground on each side at B, showing that no view can be obtained there. At C would be the position for Araucarias, &c.

Fig. 3. Supposed line across and on each side of the valley from A, so as to give some idea of the expanded magnificent view.

whatever. That a clear judgment may be formed, we subjoin *fig. 1*, which represents a line drawn at something like 60 feet to the inch from the falling park at A on the west side, to the rising park at B on the east side, passing the grass, terraces, and slopes, the gravel terrace at entrance front, D, the mansion, C, the flower garden, E, and the rising park beyond. Suppose you stood on the east front of the mansion, or at any part of the line E, in the flower garden, you can see little beyond the garden if disposed to try, as the ground rises in a glade in the centre and swells to the north side and rises more abruptly and steeply on the south side, until the park loses itself in dense, beautiful woods. But just return to the west side and stand upon any part of the terrace at D, and either look down along the slopes and grass terraces, and the beautiful valley, or lift your eyes and

allow them to sweep the grand panorama on each side of that valley, a cross line of which, *fig. 3*, gives no idea, and then say if you would not vote for that side of the mansion being made the garden front, and that the windows of the best rooms should have commanded that prospect.

From the plan of the flower garden (which see) an idea may be formed of the size of this fine Grecian building, built, as well as the offices, of heavy greyish limestone, but from there being only one wing, and the handsome and commodious stables and yards being clustered to the north and east of that wing, the mansion though massive in its appearance, is somewhat one-sided, and therefore at present so far unsatisfactory.

The terraces on the west side have been well laid out, and are beautifully kept. The width of these terraces and slopes is

given on the sectional line. The length of the gravel is 232 feet, of the top verge of grass 261 feet, the first slope 300 feet, the level landing 348 feet, and the slope reaching the level of the park about 370 feet, nicely finished and levelled at the ends, and lengthening as they reach the valley.

Now, let us open the gate and get into the beautiful small flower garden, the very simplicity of the arrangements adding a charm to the superior management. For all that is said above, do not let it be supposed that we do not feel that such a shut-in garden has many advantages. To many calm, retiring spirits it would be more prized than the most splendid combination of terraces, and owners in all such matters will and should consult their own tastes. This garden breathes the very essence of comfort, repose, and tranquillity. Dazzling magnificence is quite another affair. One thing seemed to intimate that some arrangements were yet in abeyance. At the north end, close to a high wall already there, a site remains set out for a large conservatory, with a raised, swept-in, semi-circular terrace of gravel and grass in front of it. A communication could be made easily between such a conservatory and the wing part of the mansion. From that conservatory and the terrace in front of it, as fine a view will be obtained of the garden as from the windows in the mansion. The only objection will be, that the conservatory and terrace at one end will form the chief points of interest, unless in the way of uniformity there is something of a similar character attempted at the other end. Taking these things into consideration, and keeping ulterior objects in view, we should clothe the wall at the north end of the terrace, devote the terrace itself to a distinct style of gardening, and build a span-roofed, architectural conservatory at the south end of the mansion, which would thus obtain light from all directions, except the north be a balance and counterpart to the north wing of the house, and interfere less with the unity of the present flower garden, whilst a communication could at once be formed between the drawing or dining-room (we forget which) and the conservatory.

The flower garden at present is bounded by a low balustrade, surmounted by a stout, elegant iron fence, separating it from the park. There is no attempt made to conceal the fence, nor is there reason for doing so; but between that fence and the walk there is a broad margin—say 25 feet of turf—and shrubs are so placed on the turf singly and in groups that they hide the fence in some places, and show it in others. There thus seems to be a conflict of aims which would not appear if the shrubs were thick enough to conceal the fence altogether, or thin enough to permit each to show itself separately. At present they form a good background to reflect the rich colouring of the flower-beds, and, to a certain extent, protect them from the east winds that must come sweeping down the incline of the park. Most of these shrubs, too, so far as we recollect, were flat-headed—as Laurels and Arbutus; whilst those of a more spiral character would have been more telling in contrast with the horizontal lines of the mansion. We could see that Mr. Milroy was dissatisfied with it, but did not glean how he would wish to alter it. Hardly anything is more difficult than to do such outside boundaries satisfactorily. Shelter, background, and contrast might be obtained by planting the shrubs in an irregular belt near the boundary, and then having a straight row all round of upright pyramidal trees on the grass, and far enough apart from each other—such as Cypress, Juniper, or the Irish Yew, grown not as bushes, but to a single stem, and allowed to feather out. If any alteration is made we should be glad to know what is determined on.

Talking of shelter reminds us that in this large place there is little of the exotic in woodland scenery—at least, we do not recollect much of that as a feature. Now a few spiral evergreens outside near the east boundary, and some small groups of the hardiest and showiest Pinuses in the foreground, and Peonies, Araucarias, and Wellingtonias on the steeper banks on the south side, would alike yield to shelter, and prove a distinct feature and object of attraction.

The width of the garden on the south side is 235 feet. For the chief bulk, from that you must deduct the width of the mansion. The length from the boundary wall on the north to the balustrade on the south is 278 feet. The garden, notwithstanding the winds and rains, was a perfect blaze of colour, each bed full to overflowing, and far less of foliage seen than we could have expected after such rains. It was thus planted, beginning at the steps from the saloon. At first the beds being opposite, and then the cross system of planting being adopted, I, 1, Golden Chain and

Lobelia speciosa; 2, 2, Heliotrope edged with Scarlet Ivy-leaved Geranium; 3, 3, Blue Bonnet and Prince of Oude Verbenas; 4, 4, Punch and Tom Thumb Geraniums; 5, 5, Mrs. Lennox and Silver Queen Variegated Geranium; 6, 6, Rose Queen and Christine; 7, 7, Countess of Warwick and Flower of the Day Variegated Geraniums; 8, 8, Commander-in-Chief and Cerise Unique Geraniums; 9, 9, Aurea floribunda Calceolaria and Prince of Orange Calceolaria; 10, 10, Lord Raglan and Brillante de Vaise Verbenas; 11, 11, Alphonsia and Géant des Batailles Verbenas; 12, 12, Kayi and Viscosissima Calceolarias; 13, 13, Purple King and Ariosto Verbenas; 14, 14, Alma and Annie Variegated Geraniums, each bordered with blue Lobelia; 15, 15, Bridal Bouquet and Bijou, each bordered with Lobelia; 16, 16, Shrubland Rose and Smith's Superb Petunia, bordered by Variegated Alyssum; 17, Blue Salvia, strong plants of Lady Plymouth Geranium, and Perilla nankinensis; 18, Gazania splendens, edged with low border of Variegated Mint; 19, 19, dark Purple Zelandia Dahlia, bordered with rich wreath of Mangles' Variegated Geranium; 20, 20, Trentham Rose and July Cerise Geraniums; 21, 21, Imperial Crimson and Newell Geraniums, two fine match beds; 22, Heliotrope in front of a principal window; 23, 23, as terrace; 1, 1, Lobelia Roi Leopold; 2, Fairy Nymph and Attraction; 3, 3, Lady Dorothy Nevill and Lady of Loretto; 4, 4, Général Pelissier and Masterpiece.

It may be useful to mention a few facts respecting some of these plants, the results of observation and the statements freely given by Mr. Milroy. Newell, a dwarf, crimson Nosegay Geranium, grew freely and bloomed most abundantly though the season was so wet. Imperial Crimson, two shades darker, does equally well. The two make fine match beds. Countess of Warwick is considered the best Variegated, a strong grower, a fine bloomer, and keeps the bright horseshoe mark almost as fine as Attraction in that respect, but vastly superior to it in habit and colour of flower. A match for it would be an acquisition. Bridal Bouquet, Alma, Annie, and others only do well in dry weather. Conway's Princess Alice and Emperor of the French are too strong growers for beds, but do admirably for pots. Trentham Rose, and what is called July Cerise, match well, Masterpiece, Richmond Gem, and Général Pelissier, ditto; Lady of Loretto, and Lady Dorothy Nevill, ditto; and Bijou and Mrs. Lennox, as Silver-edged. In Pinks, Christine, and Rose Queen, first-rate matches and a mass of bloom. All salmon colours are only fit for pots in that moist climate. I noticed also many others, as a strong-growing King of Scarlets, a bright scarlet, General Simpson, Mrs. Smith, resembling Rubens, and many others under a course of trial.

Leaving out of view the background given by the shrubs already referred to, the great charm of this garden consisted in the grouping of the beds round the fountain, the open space thus secured by water and gravel for repose, and the comparative thinness with which the beds are placed on each side. Had the whole space been covered with beds as thickly as those round the fountain, a vast number more plants would have been required, and the effect on the whole would have been anything but heightened. For these beds, and for the conservatory when it comes, even if everything else continues as it is, a preparatory establishment near at hand will be requisite. We presume that at present the plants are taken from the kitchen garden.

Outside, again, on the terrace of gravel we noticed how clean and nice it was. The approaches, too, as far as we saw them, had been very substantially made. We were little on any of them, except the one leading north-eastward in the direction of the farm. The gravel, after heavy rains, was smooth and firm, the curves very easy and graceful, the grass verges short and green; both sides planted with deciduous and evergreen trees; one side rising into swelling mounds, and the other side sinking into glades and glens. With all this there might have been monotony; but this is thoroughly avoided by the variety given to the width of the grass margins. Now a shrub comes within a couple of feet of the roadway; anon a bold sweep of lawn, from cutting out and thinning; again a lesser sweep, along which the eye passes as traversing a line of beauty; and thus from end to end there is a constant succession of change that cannot fail to be pleasing. There can be no mistake about it. The eye of the artist was necessary to form that roadway; the eye of an artist is just as perceptible and as necessary now to prevent the beauty becoming monotonous.

The dignity of the mansion is enhanced by the fact that the approaches rise to it. Standing on the gravel terrace you can see that on the south and the north sides winding up the hill.

There is not much to be said against this, farther than that the best road is no ornament in itself in extended park scenery. In an avenue leading straight to the entrance-door this cannot be avoided. Approaches entering on the gravel front at right angles should be seen as little as possible before they get there. This could be managed easily in the present case. On the north side especially the road comes near enough the sloping terraces for complete safety on a foggy night. A group of trees already exist, behind which the approach could wind as gracefully as now and enter at once on the terrace. So much for the terrace. I have dreamed, however, and that repeatedly, that the day will come, though I may not have the happiness to see it, when the improvements on the estate, and the comforts of the workpeople (now, as it is right they should be, matters of the first importance) shall be carried so nearly to a point of completion, that such a craving will be felt to find something fresh to do and to obtain an outlet for the increased rent-roll, that these fine approaches will be swept round to the now garden front. A splendid conservatory will adorn the south side of the mansion, and these wide terraces of gravel and grass, now somewhat meaningless, will be changed into one of the best examples of Italian artistic gardening; and then even Chatsworth and Shrubland will have to look after their laurels lest a rival should come from the Emerald Isle to contend for, and to win and wear the wreath of the conqueror.

R. FISH.

(To be continued.)

PREVENTION OF THE POTATO DISEASE.

I AM not surprised that Mr. Pownall should take exception at my remarks on his paper of the 3rd instant. In taking up the pen on a subject with which personally I was practically unacquainted, I laid myself open to attack. I beg to withdraw my charge of Mr. Pownall's rashly and publicly condemning the system. I still maintain that the printed directions are "plainly and lucidly expressed," and can bear but one meaning—viz., that the Potato haulms are covered entirely with earth. But, in conversation with Mr. Shortt, I discovered that this was not what he himself intended to convey. Mr. Milford wrote the letter in question, and he held the opinion that the whole haulm must be covered. Mr. Shortt, at the time, objected that such was not his view or practice; but the paper was not altered. Mr. Shortt's own practice is, as stated in the footnote added to my remarks, previously in the hands of the publisher.

This will tend to prove that both systems will answer in arresting the disease; but the total covering of the tops would, doubtless, put a stop to further growth in the tubers.

I still maintain that, take the printed directions as they stand, or modify them to suit Mr. Shortt's real intention, Mr. Pownall himself misapprehended their meaning; that to twist the tops, "hayrope fashion on the centre of the ridge, and then put the earth of the furrow over that," was totally at variance with both the spirit and letter of the text. Although the words, "If I understand it aright, the principle is," &c., were used by me, I did not in the least intend to imply that there was the slightest shadow of a doubt in my own mind as to the meaning of the written directions. Besides, Mr. Pownall will see that I used this expression in the footnote, after having been informed by Mr. Shortt of the error contained in the published letter. From a conversation of only a few minutes' duration, I might not have felt so qualified to speak unreservedly as if a paper of written directions were lying before me.

I am not acquainted with the amount of crop obtained by Mr. Shortt, but understood it to have been a good one; but with regard to the amount of disease, it may truly be said that the exception proves the rule. Four tubers only were affected, and these were taken from the extreme end of a row, which were not perhaps so well protected by the earthy covering.

Although the system has not been personally tried by me, yet I have seen it carried out in my father's garden; and, as stated in my last, with satisfactory results. Perhaps a garden under my own care would not have afforded me a better opportunity of watching the experiment.—S. BEVAN FOX.

TREE CARNATION THE BRIDE.

My employer purchased the Bride, with some others, twelve months ago. I have now two fine plants in flower. The flowers are pure white, and as large as the old Boule de Feu; very

sweet scented, quite equal to the Clove. No person ought to be without it that grows Carnations. The way I manage after getting them from the nursery, if at all leggy, is to peg them down in the pot. In following that plan, I have grown them 3 feet through and the same in height by the second year; and they flower from October till February.—B.

FLUE HEATING A CUCUMBER-HOUSE.

I HAVE a lean-to house that I think of growing Cucumbers in. Along the front wall, looking south, is a brick pit, 3 feet wide and 3 feet 4 inches deep. The furnace is at the east end. I think of running a flue, three bricks-on-edge deep, carrying it along the centre, and bringing it back by the north wall, which is 8 feet 6 inches high. Shall I get bottom-heat enough, and what height should the slate be above the flue, and what is the best covering to get the greatest amount of heat? Would slate do at 8 feet from the furnace? Also be so good as to inform me if I should leave any holes in the wall to let the heat out into the house, and at what distance should they be above the flue, how large and how far apart.—L. B.

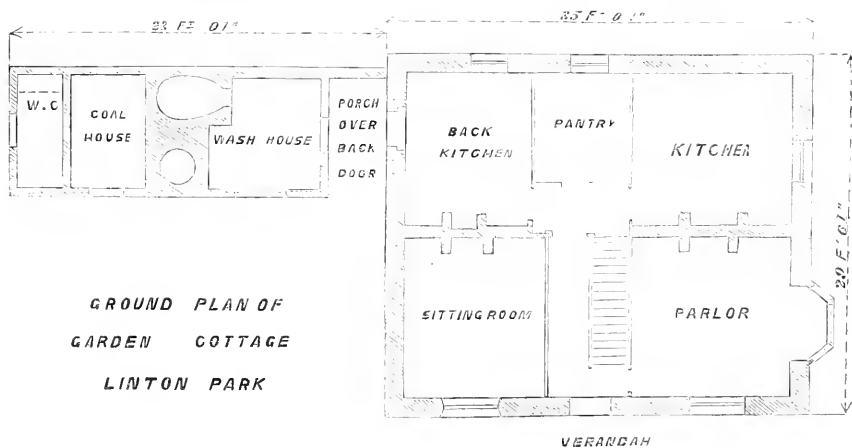

[We have said so much about all sorts of heat from flues lately that some of our friends tell us we are getting flue-crazed. There is not a single idea we can advance but has been given to repetition in late Numbers. We should prefer your flue for 3 yards or so from the furnace to be brick-on-bed—in fact, for a lasting affair, if we did not have it so high, we would make the whole of the flue in this pit brick-on-bed, and that open in the house brick-on-edge. Have stout slate by all means a foot above the flue, if such you prefer. We have scores of times stated what we like better, and which cannot waste or break, and that is clinker and rubble, finishing with fine-washed gravel before we put the soil on. You might have an opening in the side wall every 5 feet of 16 inches by 6 inches if you forced early. If you did not commence until February or March you would need no openings at all; the flue in the house will give plenty of atmospheric heat. We presume you do not mean covering any part of the flue with slate. As to the coverings that would give the greatest amount of heat, we do not know whether you mean coverings on the glass or coverings on the flue. In the former case the best covering would be rough wool, covered with a waterproofed surface.]

CUTTING DOWN OLD LEAFLESS HOLLIES.

WILL you inform me what I ought to do with my Hollies? The last winter killed all the leaves and twigs. In the spring the twigs were all clipped off, leaving long bare arms standing out in all directions. These boughs last summer put out a cluster of short spurs at their extremities; all the rest of the branches are bare. Small shoots here and there grow out of the main stem. I fear me these long naked branches with their tufts of green leaves will never put out sufficient shoots to hide their nakedness. These trees used to hide very completely ugly walls, and I am afraid, judging from their present condition, they will never make a cover again. Am I right in my forebodings? Should I prune all these branches off close to the main stem, or should I dig the trees up (trees from twenty to thirty years old), and start afresh?—AN OLD SUBSCRIBER.

[At the end of next April cut the injured Hollies completely to the very surface of the ground. That is the only plan by which to test whether the frost was the real cause of their dying so much, or if the cause might not have been at the roots. If the frost was the cause you will have abundance of strong healthy shoots up directly from the roots, or stools as gardeners call them, and some of the young shoots will be from 3 feet to 4 feet in length, or ought to be from stubs which are between twenty and thirty years old. *Recollect*, however, that if you leave only 4 inches of the old stems above the ground uncut, you will miss the mark. This caution is not for yourself only, but for all whom it may concern about Hollies. It is well known that old injured Hollies will keep for forty years in a state between starvation and death; and it is equally well known that if the roots are good they would start afresh in forty weeks, if the whole of the plants above the collar or ground-line were cut off. Also, that if any lengths of the old stumps are left the roots can hardly budge. If your stools are not in prime promise by next October, grub up the whole lot at once, and have done with them. Trench and drain the ground and "start afresh."]

GARDEN COTTAGE AT LINTON PARK.

In the cottage, of which the above is an engraving, resides our able correspondent, Mr. Robson. It is substantially built of Kentish rag stone, with oak timbers, and the roof of plain and scollop tiles in alternate rows. It is situated in the park a short

distance from the garden, and being on a rising ground with its principal front to the south, it is perfectly dry;

We also give a ground plan, which shows four rooms and a pantry, and on the floor above these are four good bedrooms and a stove closet. There are also two good cellars underneath the two front rooms. The outbuildings, consisting of a wash-house, &c., are also good, the whole being well fitted up in every way.

As some inquiry has been made through our pages of Pitch Pine as being suitable for hothouse buildings, we may say that the staircase of this cottage, as well as some excellent cupboards, window-shutters, and doors, are fitted up with this wood, which being varnished looks remarkably well.

Another room (the parlour), is fitted up with oak of home growth, and looks also well, no paint being used, and it is a divided question whether the Pitch Pine or the English oak looks best. Both are certainly good, as likewise is everything connected with the cottage. Elarel's kitchen, we were told, answers there admirably as a cooking apparatus, and, altogether we have seldom seen a house, which, without assuming any uncalculated or outward show, contained so much of the aids to real comfort.

Now, Mr. Robson is head gardener at Linton Park, and the question then arises, Is such a cottage suitable, and to be recommended as a model residence for those who hold a similar situation?

To this a qualified answer must be given. For a head gardener at such a residence as Linton Park, fully qualified by education and attainments, and with a fitting salary, we do recommend Mr. Robson's cottage as an example of what a head gardener's dwelling ought to be. Its extreme neatness, its good, appropriate, and well-ordered furniture, are evidence not only of the mistress of the house being an excellent manager, but that the means are not deficient.

Where a gentleman does not reside in a mansion equal to that of Linton Park, and where the gardens are less extensive and the salary paid to the head gardener is smaller, then we advise that a less garden cottage, but one not less comfortable, be provided; for being over-housed is as great an evil to a gardener as to any other member of the community. In proof of this we give the following extract from a letter we received some little time since:—

"I know a gardener's cottage that cost more than £800, and the wages of the gardener are £70! How can a man with a family prudently furnish and keep such a house on such an income? I find that this furnishing of a house, and gentlemen expecting it to be respectably furnished, and on less wages than the above, is becoming a fruitful source of annoyance. I know one of the best gardeners, who is just now tied by the leg. He has done an immense amount of first-rate work, as artist, architect, and all the rest of it, and his wages have not been raised according to agreement; but in furnishing a large house he has parted with his ready money, and he feels himself thoroughly tied by the leg."

CONSTRUCTION OF A GREENHOUSE.

I AM about to erect a cool greenhouse of the following dimensions:—33 feet 6 inches, end to end, 12 feet (in the clear) back to front.

The roof is hipped. The ventilation I propose to have by means of the two end-sashes (under the hip), hanging in the centres; every alternate front sash will also open on hinges. Will this give sufficient ventilation? as the roof will not be moveable sashes, but fixed sash-bars. These will be 2½ inches by 1½ inch.

The framework of the roof will be nine rafters 5 inches by 2½ inches, the ridge 5½ inches by 3 inches three tie-beams 6 inches by 4 inches from head to plate on back wall. Will this be too heavy, or obstruct the light too much? Would not a less number of rafters be sufficient? if so, what number would you advise? Would a less number of rafters and stouter sash-bars be advisable? The sash-bars would have an iron rod running through the centre from end.

In addition to the tie-beams there will be some three-quarter-inch rods from the bottom of the hip to the front roof. The top hip and back will be glazed with one-eighth-inch rolled plate. The glass on the roof will weigh some 700 lbs or 800 lbs., as I shall use one-eighth-inch rolled plate in size 10 inches by 12 inches.—OLD READER.

[There is no question but that by the means you propose

you will have a very substantial house; and we would not like to interfere with your own plans, as you will like them best. Your cross-bearers might be one-and-a-half-inch iron rods, instead of wood. The number of your rafters does away with much of the economy of a fixed roof. For such a house ten such rafters at the ends, and two unequal divisions along the middle, 4½ inches by 3 inches, would be sufficient. Two cross-bearers might go for these two in the middle to the back wall, and beneath them a pillar of wood or metal might be placed for your sash glass; sash-bars might be used 3 inches by 1½ inch. If you run an iron rod all the way in the middle fastened to all the bars there would be no danger. However, we do not want to interfere with your plan, for it will be stable and lasting. You will not have enough of ventilation at the back. Every other sash should open; and if you object to open the doors, a piece at the angle of the roof at the end should also be made to open.]

DIFFERENCE IN TIME OF FLOWERING OF CROCUSES IN THE HOUSE.

NEMOPHILA INSIGNIS BLOOMING IN DECEMBER.

Will you inform me why Crocuses planted in soil in an ornamental pot on the 13th of September, are not more forward than some planted on the 8th of October in tin saucers? Those first planted have been in a room, the temperature of which is from 50° to 60°. The others in one larger and of lower temperature. Also, can any one tell me whether *Nemophila insignis* sown in September ever flowers in the house at this time of the year? The seed sown was Carter's for autumn sowing.—MADEIRA.

[There is six weeks' difference in the time of flowering of some Crocuses in the spring. Then if any of the very late kinds were potted in the middle of September, and an early kind not till a month later, the last would now be more forward. *Nemophila* sown in September will not bloom in-doors till next March, or out of doors till April. To have it in bloom in December the seeds should have been sown the last week of June. We had it thus in bloom when snow was on the ground.]

BANKS OF EARTH INSTEAD OF SHELVES IN A GREENHOUSE.

FRUIT TREES TRAINED ON A SLATE ROOF.

In a greenhouse lately built I purpose to have, instead of the usual wooden shelf under the glass in front, a bed of earth in a wooden frame to rest the pots upon. This promises to be of service in several ways—thus, plants like the *Calceolaria* which object to too dry an atmosphere, may be plunged in it. In summer, if the roots from pots standing on it are allowed to run through, there will not be so much harm done when the watering-pot is forgotten. Seedlings again, may be raised in it. I shall have an opening of 2 inches broad running along the bottom of the frame covered with wire, and give the wood on either side a gentle slope towards this opening for drainage. If this wood were covered with galvanised iron or zinc, would it injure the roots?

Could we grow Vines on such a bed if it were a foot deep? On the rocky terraces of southern lands they flourish in less depth of soil than this.

I once saw some fruit trees, in Scotland, trained over a slate roof. Having a limited garden and some outhouses convenient for the experiment, I have planted some Pears to be trained in this way. A slate roof must be much hotter than a wall. Will you tell me whether slate will scorch and injure fruit where it touches it? If so, the wires on which the branches rest must be at least 6 inches from the slate.—WYE SIDE.

[You leave us a little in doubt as to the whole of the questions from not stating the width and height of the proposed bed instead of a shelf. The plan has been recommended in these pages for several purposes. *Calceolarias* and *Cinerarias* will do well out, but better not plunged. This may be too much for them, and they might so root out below that you could not move them without injuring them. Mr. Fish has several times stated how unsuitable such beds are for *Pelargoniums*, especially in winter and spring; but you could accommodate them with a board, or set them on a reversed pot. As a rule, inside of a house you will find it best to raise seedlings in pots, because you can move them just as you like to harden them off, &c. Iron pro-

bably will not do much harm under the circumstances, and zinc is liked by the roots of almost all plants, but if you have a front wall to your house, would it not be cheaper to run up a four-inch wall of brick inside, with a nine-inch pier every 8 feet or 10 feet for the inside boundary of your border, and by having holes at the base every 4 feet or so, you would let the drainage out, unless, indeed, you have a pipe below the border to take extra water outside the house at once, which would be better still? You might then have 6 inches or more at the bottom of open rubble for draining. If you have 2 feet or 3 feet in width, you may manage to grow good Vines in a depth of 12 inches or more, if you manure tolerably well on the surface. If you so use it for Vines it will be advisable in placing plants on the border in winter to place saucers beneath them, and even in summer to beware that the surface of the border is not soaked in some places and too dry in others. This plan would obviate the necessity for any wire bottoming. Your reference to southern lands is not quite analogous, because often with only a few inches of soil the roots can penetrate a good depth into the crannies and openings of rocks. However, with the cautions alluded to, we have no doubt but you will succeed. If you must use wood instead of brick, then we would advise you neither to have zinc nor iron, but have two boards, the outside some 1½ inch thick, and it will last longer if not painted, and an inner board separated from the outer by an inch of a division; this inner one to be half an inch thick, and pitched on both sides. So done it will last a long time, and when it decays you may slip down another one whilst the outer board continues fresh and good. A great deal of money is used in such cases for painting to make things look nice and hasten decay.

There will be little danger for trees on slate roofs, provided when young the branches do not absolutely touch the slates in hot days—an inch or two will be quite sufficient. When the trees pretty well cover the space, the branches will take no harm if they touch the slate, as the leaves will defend them. The slates will be warmer than a lighter wall in sunshine, but colder at other times, and in the hottest days the air a few inches from them will be cooler than if the wall was lighter.]

GAZANIA SPLENDENS.

To judge from the remarks of some of your correspondents, as a bedding plant the *Gazania* has not given them satisfaction. Notwithstanding their fierce onslaught upon its deficiencies, I have pleasure in fully endorsing Mr. Beaton's opinion respecting it. When gardener at Lennox Castle, in Stirlingshire, I employed it as extensively as I possibly could; and, notwithstanding the season proved to be one of the worst on record for bedding plants, it gave me every satisfaction, as well as all others who saw it, especially my employers. When visiting Dalkeith late in autumn I saw it in fine condition. Mr. Thomson employs it alone with *Calceolaria aurea floribunda* with good advantage; its robust habit acting as a good support to the *Calceolaria*. I purpose employing it here (north of Ireland) next season somewhat extensively, feeling convinced, from what I have had to do with it, that I shall not be disappointed.—
JOHN ELLINGTON, Gardener, Crom Castle, Newtown Butler, Ireland.

WORK FOR THE WEEK.

KITCHEN GARDEN.

Cauliflowers, during the present very mild weather the glasses should be left off day and night, to prevent their drawing. Diverst the plants of dead leaves, and look frequently for slugs. *Celery*, as it still continues to grow vigorously it will be necessary to earth it up, that whenever frost may set in it will not be injured so much as it otherwise would. *Herbs* to be taken up, and planted in boxes or pots, and introduced into heat as wanted for use. *Lettuce*, the young plants in frames to have the glasse left off day and night during mild weather. Watch narrowly for slugs, as they are particularly fond of this plant. *Mushrooms*, horse-droppings to be now saved for spring beds: this is the best season for saving them, as horses usually have more dry food than during the summer. The beds in bearing to be cleared from wet litter about every week, and a covering of dry hay put next to the bed, over which must be laid sufficient dry straw or other covering to preserve the beds from frost.

Rhubarb, keep up a succession of this most useful esculent by potting old roots, and introducing them into a heat of 60°.

FLOWER GARDEN.

Shrubs may still be planted in favourable weather in all ordinary garden soils; but where the ground to be planted is of a clayey nature, and in an unkind state at present, it will be better to postpone planting until spring, meantime using every means to improve the state of the ground by digging, or trenching and ridging, for greater exposure to the pulverising influence of frosts and thaws, to bring it into a better state for planting in the spring. Rose-borders and beds to be well dressed with manure, which should be forked in lightly so as not to injure the roots.

FRUIT GARDEN.

Some wall trees—as Pears, Plums, Cherries, &c.—are often attacked by a species of scale insect: where such enemies are visible the infested trees should be well washed with a mixture of soft soap, tobacco water, and lime; half a pint of turpentine to be added to four gallons of the mixture when they are much infested. The lime is added to give consistence to the mixture, and to show that no parts of the tree are missed in dressing. The mixture to be applied, if possible, in dry weather, that it may remain on for some time. Apple trees against walls, or as espaliers, to be pruned. Cut off that part of the spur which bore fruit last summer down to the fruit-bud formed on the lower part of the stem of the spur, taking out all bruised or cankered branches, and leave a regular supply of wood throughout the whole. In pruning, cut away all shoots from Gooseberry trees, except one or two springing, as near as can be obtained from the origin of each main branch. Shorten the young shoot left at the top of each branch to about ten or twelve buds, and leave throughout the tree the fruit-bearing branches about 6 inches apart. In pruning the Currant keep a good supply of young shoots springing from the bottom of the tree, and cut out more or less of the old every year, never allowing a branch to remain more than four or five years, and head in the young shoots at the top to about two eyes of the main branch from whence they spring. Where the Gooseberry and Currant trees are old and covered with moss a good dredging of powdered quicklime put on when the bark is moist will entirely destroy it, rendering the stems clean and the bark healthy. Prune the Raspberries in the open quarters; cut away all shoots that bore fruit last summer.

STOVE.

A moderate heat from 50° to 60° to be kept up with plenty of air. The *Ixoras* to be elevated near the glass to set their bloom; keep them comparatively dry. *Stephanotis*, *Allamandas*, &c., to be potted and trained preparatory to starting them into growth after Christmas. The staking of all succulent plants to be proceeded with in weather unfavourable for out-door operations.

GREENHOUSE AND CONSERVATORY.

We are now arrived at that part of the season when the nights are at their greatest length, and the few hours of light we have are but seldom clear and bright, and the external atmosphere often changing, so that the utmost caution is required in the application of heat, air, and moisture. Thorough cleanliness to be maintained, every decaying leaf and blossom to be at once removed, and every kind of plant to be supplied, when dry and approaching a flagging state, with tepid water. In addition to keeping the conservatory gay with blooming plants, let the arrangement of the pot plants be occasionally changed by grouping the plants somewhat differently, and adding a few striking ones—as some of the hardest Palms, &c.—for effect.

FORCING-PIT.

Introduce such plants as are generally used for forcing, especially the sweet-scented things—Lily of the Valley, Sweet Briar, Lilacs, Roses, and bulbous plants. All plants intended for forcing to be kept under temporary covering of some kind—an open shed, or under the stage of the greenhouse. When *Achimenes* and *Gloxinas* are required to bloom early, a few pots may now be started in bottom heat.

PITS AND FRAMES.

As a change from the present mild to severe weather may come on suddenly be provided with ample means for covering these structures, should it occur. Mignonette and Neapolitan Violets will require an abundance of air to keep them from damping. Keep the bedding stock well ventilated, and the

surface soil of the pots frequently stirred. Dust with sulphur Verbena and any other plants attacked with mildew. Anything of which there is but a sparse supply of plants to propagate from to be placed in warm quarters at once, taking care to keep them near the glass, and free from insects, mildew, &c.

W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

Slightly forked among young Cabbages, planted a few more in case, with all our checking of growth of the earliest, a severe frost might be too much for them; but we hardly think so, as the leaves have been a little flaccid in bright sunshine ever since, which will enable them to stand frost better. Gathered any withered leaves from Brussels Sprouts, Scotch Kale, &c., so that the garden should have no unpleasant smell. Slightly forked again the Strawberry-quarter, to keep the surface loose until we get a frosty morning to give a little rotten-dung dressing between the rows. Collected leaves by the side of Box-edgings where they had blown by winds, and swept and rolled walks. Globe Artichokes and other things liable to injury being previously protected by litter.

FRUIT DEPARTMENT OUT OF DOORS.

Top-dressed young fruit trees, pruned and nailed when convenient. Gave all the air possible to lean-to orchard-house. Washed wall trees, as Pears, Cherries, &c., with soapuds, with a handful of salt to three or four gallons, which helps to keep the stems free of moss and insects. If the suns are warm—say 110°, it will help much to clear shoots of scale. Cleared and whitewashed walls of houses in bad days, and thus filled up holes as much as possible, as avoiding nail-holes, we prefer wire trellising decidedly under glass for fastening trees to. *Streets* and the holes made by *nails* are the best of all harbours for insects' eggs. Even on the open wall it is bad policy to use a shred a second time before it has been boiled in water, and then dried before using. Even nails are all the better of getting a good toast over the fire in an old kettle or shovel. In the case of decayed shreds fastened to nails, the burning process is the quickest and best for getting at the nails; as, passed through a sieve afterwards, all the ashes and bits of lime, &c., are at once got rid of. Many holes are made in walls quite unnecessary when nailing is adhered to by at once pulling the nail out of the wall. It should always be tapped on the head gently at first, which will so far prevent it bringing a piece of the plaster and wall with it when pulled out.

PLEASURE GROUNDS.

The leaves having now mostly fallen, have had on dry days all bands spareably cleaning and sweeping up, as decaying leaves either on grass or gravel have always a melancholy aspect, and besides every one of them may be turned to good use in the compost-yard or the fermenting-heap. The *walks*, from being so smooth, have become in shady places a little greasy on the surface, and after sweeping off what could be thus had, the teeth of a short-toothed rake were drawn through the worst places, just to make them rougher, and let the slight showers wash the surface; and then, as soon as a little dry, they will be rolled again, and present a comfortable foothold for the feet. We are no great advocates for digging walks at any time, there is so much trouble in getting them solid again, and more especially in winter. Kept digging up the flower-beds not planted as opportunity offers. A smooth lawn free of worm-heaps is a pleasant sight in winter. The safest remedy for worms is watering with fresh limewater. In rolling there is no necessity for the roller being heavy; we generally for such a purpose use a wooden one formed of a piece of a tree about 1 foot in diameter and 4 feet long, with wooden handle. This is very light, and even a stout lad can move it over a large space of lawn in a few hours. If the lawn is rough a heavy iron roll should be used at first. When there is continual rolling worms do not like it, and are induced to keep lower down out of the reach of the noise and racket.

IN-DOORS.

A fresh bed was made in the *Mushroom-house*, adding a little at a time for a fortnight, and treading and beating hard to keep out the air. At this season the difficulty is to get it dry enough, and, therefore, we were obliged to put a little fire heat on, and to let out the steam, which would have damped the beds too much. Fresh manure put in a low bed was covered with turf

soil to keep down any damp steam in this dull weather. The turf will make the bed all the more lasting. The bed referred to above has been spawned to-day, wrapping each piece of spawn about the size of a walnut in a little dry litter before inserting it, and, as the heat seems all right, will earth up in a day or two. As I stated the other week, could I get enough of material in summer I would fill the most of the beds in the Mushroom-house then, and leave them unspawned, and then when I wished to set them going I would mix 3 inches or so of fresh droppings with the bed, which would make it heat kindly; and when all right in that respect, insert the spawn, and cover with soil. We have done the same thing with boxes and large pots, and thus kept up a regular supply with them by spawning in succession. We consider this a better plan to depend upon than using large beds and large boxes, and expect them to produce almost continuously. In some cases they will do so, but in others they will not produce longer than a shallower bed, and then, as the coachman said, "Where are you?" when he contrasted his steady secure-going pace with the smash of the railway train.

Several correspondents have inquired, What is the best material for the shelves or beds of a Mushroom-house? and I say at once, Stone or slate. What I use is nothing fine, and is simply wood, and as a piece rots we add another. When that is the case, a sparred bottom—say made of pieces 3 inches wide, and 2 inches thick, and 2 inches apart, will last longer than a closer one, or boards close altogether. They are also more useful in two ways. Supposing that the upper bed is made first, and does not come as soon as you like, then the preparing for the under bed will throw a little heat into the upper one, and set the spawn a-working vigorously. When the bottom is thus open a crop can often be had below as well as above. Thus some long litter is thrown over the spars to prevent the shorter material falling through, then an inch or so of turfy soil is added; and if the bed is made at different times, so as not to heat violently, pieces of spawn may be strewed over the turfy soil before the layers of manure are added. In such a case we have had the bottom of the bed throwing out plenty of Mushrooms between the spars; and what is rather singular, though most of the Mushrooms will grow downwards so as to be easily gathered, many will turn back, and try and get their hooded tops upright into the bed again. I have found this more general in proportion to the darkness of the house.

MUSHROOM SPAWN MAKING.

This leads me to recollect, that, besides a correspondent to-day, I have had seven inquiries lately as to the making of Mushroom spawn, and all saying they can find nothing about it, though if my memory does not fail me, it was fully described about July or August, the most convenient time for making Mushroom spawn, because the material can be so easily dried. However, with shed room, or the means of drying under glass, &c., Mushroom spawn may be made at any time. There are many ways and many materials for making it, and so far as I know, successfully. I will describe one of the simplest. The quantity may be just what you like, but in similar proportions. Take a barrow-load of horse-droppings as fresh as you can get them, and with nothing but their own moisture. Then pick up half a barrow-load of cowdung as thick as you can get it. Break the horse-dung nicely, either through the hands, or passing it through an inch sieve. Then mix the cowdung and the horse-dung thoroughly together with a spade, fork, or mallet. The better it is mixed the better it will be, and if no water is required so much the better. The mass should be like stiffish leaven. If too thin when beat together, we have cut up some dry litter or straw half an inch in length, and mixed with it, to give it consistency, as the stiffer it is, like thick mortar, the sooner it will dry. The heap being all ready, make a little frame, as if for brick-making—say two boards 10 inches long and 3 inches deep for the sides, and two ends 4 inches wide and 3 inches deep, nailed together firmly. Choose a flat piece of board on which to make your bricks, and wet the surface with water. Place a pail of water beside you, dip your frame into the water, and then place it on the board, fill the frame with the prepared manure, press it firmly in, and draw a spade or trowel over it to make it all level, and then a stroke on the board with one end of the frame and the other held obliquely, will bring out your brick of manure as clean as any brick at a brick-making yard. Place the bricks as made on slips of boards, or at least on a hard surface. They will soon begin to dry, and before the sides are

at all hand make two holes in each brick, one 3 inches from each end, either with your finger or with a round stick of a similar size. The bricks will require turning several times—first on their flat sides, and then on their edges, until they are nearly as dry as common bricks are before they are burned. Then these holes must be filled with spawn, and a little cowdung, &c., as before, daubed over to prevent its falling out, and a small bed of fermenting matter being made, the bricks are laid on it and built in a heap, as open as possible, so that the heat can easily pass all through them and around them, and then they are all covered over with litter. Just as in a Mushroom-bed the heat must not be too violent. About 80° to 85°, not a degree more, will do. The heap must be frequently examined, and you will easily perceive when the spawn is running, and you will find it permeated all through with small white lines, it must be removed to a dry, cool place, where it will keep good for years. If the lines or spawn roots are as large as sewing threads they are too far gone. This is the mode I generally practise, but in all cases where only a little is used, it is best to buy it from a respectable dealer.

Plants, &c., much as last week.—R. F.

TO CORRESPONDENTS.

* * We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to The Editors of the "Journal of Horticulture, &c.," 162, Fleet Street, London, E.C.

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

We cannot reply privately to any communication unless under very special circumstances.

PROPAGATING GERANIUMS BY THEIR LEAVES (*H. Henry*).—There is little or no advantage in propagating common Geraniums by their leaves; but when cuttings are made of a rare or valuable sort, every bud is of consequence. Then, instead of throwing pieces away, every bud with its leaf is rooted. The edges of the leaves of geraniums turning brown indicate the want of sufficient moisture in the air around them.

SALT AS A MANURE FOR GRASS LAND (*B.*).—Apply it in the spring with the guano; ten bushels to the acre will be enough, sow broadcast. Although the good effect of guano may be detected the second year after application, yet we prefer applying a smaller quantity annually. Salt and guano are preferable to lime as applications to poor light land.

ROYAL HORTICULTURAL SOCIETY'S EXHIBITIONS (*A Young Lady*).—Any one may exhibit either fruit or flowers, or both, although not a Fellow of the Society.

WILD FLOWERS OF GREAT BRITAIN (*Chemists*).—This work will include all native plants used in medicine. We never heard of Stainton's "Infloraria."

BANKSIAN ROSES (*E. H. V. M.*).—The yellow and white Banksian Roses never flower well if they are pruned at the same time as other Roses. The knife, or the stopping of the stem and thorn, should not touch one of them from the 1st of September to the last day of May. That is the only secret in blooming them, and of blooming them early too, if they were properly "set off"—that is, if they were cut to near the bottom the first year after planting them, and more than half way down the second year. After that, to be pruned like other Roses as soon as they have done flowering, and at no other time.

PASSION-FLOWERS AND IPOMEEAS IN A GREENHOUSE (*Eliza*).—You do not tell us what heat you propose having in the house, though that is everything as to the plants suitable. For common greenhouse to average 45° in winter, the two Passion-Flowers might be *Cobivilii*, blue; *raemosa*, a cerise, purple. And the best Ipomoea would be *Sellowii*, a bright pink, the plants being the leaves in winter. If the house is to be kept a little warmer—say averaging 50°, *Ipomoea Leonii* would be the best. To make the most of your space we should divide it into four by slate or wood, and then have the two Passion-Flowers, one on each side, and *Mandevilla sanderleana*. All these would advise you to purchase at once if you wish a quick show. Six inches may be devoted to drainage, and 9 inches to rough earth mould and rotten turf from barn, and the upper part of turfy loam and health mould, with some nice leaf mould and charcoal, and plant as soon as you get the plants, but give but little water until they are rooting in spring.

BORAGE FLOWERING (*J. L.*).—If the seed of Borage officinalis is sown early in the spring the plants usually, but not always, bloom late in the autumn of the same year.

APPLE AND PEAR TREES FREELY PLANTED (*J. B.*).—The shoots may as well be shortened a little, but it is dependently on what is wanted. If large well-ventilated trees are wanted, frame back pretty freely. If small, compact, early-fruited plants are desired, we would merely nip the points out.

LARGE BEGONIAS (*Idem*).—Such Begonias will keep in a temperature of 50°, though the leaves may get shabby, but they will stand one of 75° and look fresher. The potting depends on the condition of the plants, the soil, and what is wanted. If we merely wished to keep the plants over the winter

and the soil was fresh and in good order, we would keep the plants rather dry and coolish, and not rot. If we wished to grow on now we would give a good watering, and put them in a cold frame, and let us at first.

FURZE-BATH CURIOUSITY (*J. S. S. S.*).—We do not think we can add a single word to what we have repeatedly said of late in the growing Cucumbers in pits heated by brick flues. We do not know what you mean by covering the flue with slate. Is it to go over the common covering? We have frequently said that slate is a bad covering for flues, especially if near the fire, and that the best information to enable us to advise you how to manage your poultry to advantage.

GLASS WALLS (*J. F. L.*).—The objection to glass walls when first introduced was the small space enclosed by them. We would like 19 feet or 12 feet at the base, even better than 8 feet, and regular orchard-houses rather than glass walls. For all tender plants such firm of houses should stand nearly as high as the trees. It is your recommendation to build a house, and allowed the south front to be completely covered with Peaches, you could not expect those on the northern side to do quite so well, and if you forced the Peaches much it might be too much for Cherries. If you did not take the south trees to the top, if you had ones would ripen pretty well. All other things are no doubt worth to do well, and from all the better for the protection if plenty of air were given in hot weather.

CAMELLIA BUDS FALLING (*An Old Subscriber*).—It is not usual for unhealthy Camellias to be so covered with flower-bud. The evil you speak of happens from two causes—when the ball of large plants has been allowed to get dry in the centre, from frequent, but not frequent surface-waterings, and when the plants have become waterlogged from defective drainage. In either case it will be well to fresh-pot in February. If the latter cause should be the reason it may need a smaller pot and light sandy soil, but the bottom heat should be continued no longer than the roots begin to work freely. They may be kept in a pot until they are started, and then sown in deeper earth as the young wood is made. If deficient water has been the reason, firming the soil at the sides of the pot, and raising a mound of soil there to throw the water into and through the centre of the ball, may be all that is needed, with a little extra shade-heat when making fresh wood.

CHESTNUT DAMPING OFF (*H. S.*).—Do we understand you right, that you are getting the chestnut off with the feet to the top of the tree, to explain the whole affair of damping. The mere open door will not give a thorough ventilation, and it may get too much in cold weather. The top of the sashes should be capable of being raised, or openings should be made in the back wall, or ventilators placed in the roof back and front. If you put a fire on in dull wet, but warm weather, and could not ventilate properly, you would increase the damping and dripping of water. Air may be given pretty freely when the outside temperature is above 28°, but sparingly if below that. When in flower the temperature should be higher. Your mode of management is right; enough is respected spring forward. If you wanted them in winter you must sow earlier. We may give an outline of management, but we could only repeat what has been said. As to many ways of doing things, and yet only one right way, you are completely at sea. All the many ways may be right ones if consistently followed out according to the circumstances.

AZALEA LEAVES (*T. H.*).—On examining the leaves very minutely we thought we saw marks of where things had been on one all the rest seemed right enough, and merely showing the effects of age; for it is just as natural for an Azalea to shed part of its leaves as for a Lilac to shed all, and a Laurel to shed some. However, you are sure on inspection that there are live things on them, and that the plant is doing well, and will repeat the process several times. We are not sure of the plant; the Burning Bush is *Euonymus americanus*, which does not require a pot or a house. The Flat, or Artillery plant, is the *Pilea muscosa*, a small stove plant with a thicket of small, round, fleshy leaves, and numerous flowers. If this it will be back to clean, better cut it back to near the soil, wash it with soap and water, take away the surface soil and transfer the plant to a clean pot of the same size, and set it in a warm place; and when broke shake the old earth away and repeat. For Mushroom spawn, see "Doings of Last Week."

CLAY PAINT TO DESTROY SCALE (*J. Remond*).—This for brushing over the stem and branches of Peach trees is made in the proportions of half a pound of soft soap and one pound of sulphur to four gallons of water. Boil them together, and when cold add as much clay as will render the mixture of the consistency of cream. "The Cottage Gardener's Dictionary" shows where the emphasis is to be in pronouncing each name; but when you have any doubt consult the "Index" to the "Index."

GLASS IN FRONT OF HOUSE (*D. T. Kent*).—Sowing Italian Eye Grass was a great mistake, as the ground was intended for permanent pasture. No wonder that it is coarse, tuffy, and unsightly. We recommend that the field be entirely broken up, sown with Oats, and at the same time with seeds of the permanent grasses suited to the soil, which may be obtained of any seedsmen who pay especial attention to that object, and who advertise in our columns.

TENNIS FOR SEP (*N.*).—Let them remain where they are until February. Take them up without injuring the tap root, plant them in your kitchen garden, burying them to half the depth of the bulbs, placing a stout stake firmly by the side of each to the top, and let them stand until they are well up, and then take them to no other Turnip, or indeed, any Cabbage or Rutabaga blooms in their neighbourhood. A specimen of Globe Turnips, 12 inches in diameter is worth raising seed from.

OPERA GIRLS—TACAMAHACA (*J. G. C. Cornhill*).—Opera Girls is the popular name of *Mantissa salutaris*. It is drawn in the "Botanical Magazine," p. 13. It is described in the "Index." At the nursery of Lee & Kennedy, where our drawing was taken in June, the blossoms have been found to resemble those of our dancing opera girls, the yellow net-like making their petioles, and the outer lacinia the blue jackets with lappets, and the filaments with their appendices their arms and necks; the latter, to be sure, rather disproportionate to the former. The name of *Mantissa salutaris* is given to it because it is Elaphium tomentum, but the tree spoken of by Abercrombie as the Tacamahaca, is a species of Poplar, *Populus balsamifera*, or *P. tacamahaca* as it is called by authors.

GARDEN PLAN "Maggie".—The arrangement is original, and the planting is exceedingly well done. You have the best proportions and the best positions for the trees, and the best soil, and the best water, and the best light. That kind of design is always and in all places better on gravel than on grass.

YOUNG FERNS DRYING (E. G. A.).—This soil must be kept too damp without enough of ventilation in dull weather.

NAMES OF PLANTS (*A. Stafford's paper*).—1, *Asplenium ruta muraria*; 2, *Polystichum aculeatum lobatum*; 3, *Aspidium adnatum nigrum*; 4, *Polypodium vulgare cretatum*; 5, *Platyloma filicata*; 6, *Blechnum suceanum* (T. B.).—1, *Pteris (pyrophylla) argyrea*; 2, *Pteris (erectica) albo-lineata*; 3, *Pteris (asplenifolia) tricolor*. (V. Travis).—*Begonia argyrostigma*. It is a handsome species. (E. Roberts).—*Begonia sanguinea*.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

THE POULTRY EXHIBITION AT THE CRYSTAL PALACE.

THE popularity of the Poultry Show at the Crystal Palace has not in any way decreased—indeed, the opinion is universally expressed that the one just held has proved itself the best of any, whether the quality of the birds or the number exhibited are the matters of consideration. Perhaps this result is greatly secured from the far more extended attention now publicly rendered to matters connected with poultry year by year. In all localities fresh shows are being instituted, and these first fostering a taste for poultry breeding in their immediate neighbourhoods afterwards extend themselves by swelling the current of our largest meetings, exhibitors being anxious to secure the greater honours there held out to successful ones. From this single cause it arises that we now see so many new names in the catalogue of competitors at the Crystal Palace and Birmingham Shows. It is worthy of especial remark, too, that among these new comers are now also to be frequently found the principal prize winners. This is precisely as it should be, rivalry inevitably tends to improvement, and in no case more surely than in poultry culture. Again, any one taking an interest in these matters cannot fail to observe that those breeds most notorious for their general utility bear the most extended proofs of improvement. Poultry breeding has settled down, not as a fancy or hobby, but, on the contrary, now develops itself as a really important feature in the food supply of the people. Firmly established as it now is, little doubt remains that even greater improvements in breeds and crosses will yet ensue; nor it is not at all improbable that new varieties of poultry will be speedily added to the list of those at present generally acknowledged in our prize schedules.

The Spanish classes at the late Crystal Palace Show were of first-rate character, the show of hens and pullets being remarkably good. It may be stated without qualification of any kind that the *Dorkings* were never equalled as a whole at any previous poultry exhibition; whether held at the Palace or elsewhere, they were the leading feature of the Show. An incident connected with the exhibition of the Grey Dorking chicken class is one that bespeaks forcibly how unprecedentedly this variety of poultry is improving. It will be admitted that Messrs. Andrews, Baily, and Hewitt, who officiated as Judges, are men practically conversant with the office of arbitrators, and well up to their work, whatever contingency may arise in poultry judging; yet with their combined energies an hour passed away in awarding the premiums to this class only. Many, very many, pens quite worthy of the highest position at customary shows were here only able to attain a high commendation; and it is only fair to the arbitrators to say the amount of high commendations and commendations might have been greatly increased (and most worthily too) had time permitted. Scarcely one pen approaching mediocrity could be pointed out. The Buff *Cochins* were first-rate, Mr. Tomlinson, as of late years customary, taking the van. The cock in this pen is a gem; but we confess the head of one of the hens is so coarse as to prove a considerable drawback to an otherwise faultless trio. We drop this suggestion, that should any very close competition arise such an objection might draw the balance adversely; and with Mr. Tomlinson's large stock, no doubt an improved selection might prevent the possibility of such a contingency. Mr. Stretol's pen of Buff *Chickens* were indeed covetable; but the prohibitory figure of £75 prevented their appropriation. The Partridge *Cochins* showed at least an equality of advancement to the lighter coloured ones. The *Game* classes were worthy of highest mention, and, most singularly, not a few of the principal premiums were allotted to entirely new exhibitors. If these classes continue to increase in popularity as they have done of late years, the entries will certainly call for even additional reward; for the *Game* entries are everywhere now-a-days the most extensive, saving in some few particular cases where *Dorkings* are locally

popular. In the *Game* fowls, as a whole, the Brown Red were the most perfectly represented, the *Hamburghs*, though good, were scarcely able to maintain their position of former years, more particularly the *Pencilled* ones. A better show of *Polands* has been but rarely seen; but the old fowl (always fatal to success) of hump-back had evidently been quite overlooked by more than one competitor. *Sebrit* *Bantams*, and, in fact, all *Bantams*, were marvellously good classes. Among them were exhibited for the first time *Dumpey Bantams*—real Scotch *Bokies* in miniature—and also *Silky Bantams* quite distinct from the well-known *Silky* or *Negro* fowls, but closely resembling the somewhat uncommon *Emu* fowl.

The *Turkeys*, *Geese*, and *Ducks*, were as uniformly excellent as could be desired; and even the close test of weighing brought but little distinction in many instances.

The *Pheasant* classes proved a very great attraction to visitors. It is almost needless to say the indefatigable Secretary, Mr. Houghton, was never from his post, and that under his experienced management everything went off most satisfactorily. To that gentleman's unvarying courtesy to every one, and heart-felt anxiety for the perfection of the general arrangements, is to be attributed the now high position of the Crystal Palace Poultry Show.

LORD TREDEGAR'S POULTRY SHOW.

DECEMBER 17TH.

The following prizes were awarded:—

SPANISH.—First, J. Martin, Mildenham Mill, Claines, Worcester. Second, A. Heath, Calne, Wilts. Commended, R. Crawshaw, Cyfarthfa Castle, Merthyr. *Chickens*.—First, J. Parson, Angel Inn, Worcester, Bridgnorth. Second, W. Foxwell, Oak, Newport. Highly Commended, Mrs. C. A. Lewis, Glyn Fedr, Crichehowell; R. Crawshaw, Commended, J. Llewellyn, Caerphilly, Glamorganshire.

DORKING (Coloured).—First, L. A. Homfray, Woodlands, Newport. Second, C. Smith, Great Dunford, Salisbury. Highly Commended, Capt. F. T. Parker, Rockfield, Monmouth; J. Buckley, Pen-y-fa House, Llanelly, Caermarthen; C. J. Thomas, Bewell House, Hereford. Commended, R. H. Nicholas, Yewbery Cottage, Malpas, Newport; Miss L. Crawshaw, Caversham Park, Reading. *Chickens*.—First, J. A. Herbert, Llanarth Court, Aberystwyth. Capt. F. T. Parker. Highly Commended, J. B. Fox, Malpas, Newport; J. Buckley; Capt. F. T. Parker. Commended, J. Logan, the Maindee, Newport; F. A. Crawshaw, Cyfarthfa Castle, Merthyr; C. J. Thomas.

GAME (any variety except White or Piles).—First, J. Martin, Claines, Worcester. Second, W. Crawshaw, Ty Forest, Pontypridd, Glamorgan. Highly Commended, W. Crawshaw. Commended, R. Roberts, Llanguibby, Usk; E. G. Jarvis, Itton, Chepstow; J. H. Braikenridge, Chew Magna, Bristol. *Chickens*.—First, J. Llewellyn, Caerphilly, Glamorganshire. Second, W. Nicholas, Caerphilly, Glamorganshire. Highly Commended, J. Garland, Weston Birt, Tetbury, Gloucester; W. Crawshaw, Ty Forest, Pontypridd, Commended, R. H. Nicholas, Yewbery Cottage, Malpas, Newport; J. H. Braikenridge; W. Crawshaw.

GAME (White or Piles).—First and Second, J. Horton, Shinenewton, Chepstow. Highly Commended, J. B. Weeks, Brumyard. *Chickens*.—First, W. Nicholas, Caerphilly, Glamorganshire. Second, H. Baker, Worcester. Highly Commended, J. Horton.

COCHIN-CHINA.—First, T. Stretch, Marsh Lane, Bootle, Liverpool. Second, J. Carr, Hasel, Swansea. Highly Commended, H. Tomlinson, Balsall Heath Road, Birmingham. Commended, R. Everett, Gibraltar Cottage, Monmouth; Miss A. Wilcox, Nailsea Court, Bristol. *Chickens*.—First, H. Tomlinson. Second, J. Garland, Weston Birt, Tetbury, Gloucestershire. Commended, W. Cuff, St. Fagans, Glamorganshire; R. Everett.

MALL.—First, J. Hinton, J. J. Fox, Devizes, Wilts. *HAMBURGHS* (Golden-pencilled).—First, C. H. Wakefield, Malvern Wells. Second, A. Nutall, Newchurch, near Manchester. Highly Commended, J. Richards, Spitty Farm, Aberavenny; R. Crawshaw, Cyfarthfa Castle, Merthyr.

HAMBURGH (Silver-pencilled).—First, T. W. Walsh, Worcester. Second, J. Garland, Weston Birt, Tetbury, Gloucestershire. Highly Commended, J. Martin, Claines, Worcester. Commended, J. Martin.

HAMBURGH (Golden-spangled).—First, T. E. Thomas, Newport.

W. Cuff, St. Fagans, Glamorganshire.

HAMBURGH (Silver-angled).—First, G. Hoskins, Newport. (Second withheld.)

POLAND (Black with White Crests).—First and Second, T. P. Edwards, Lydbury, Haris.

POLANDS (Golden or Silver).—First, Mrs. Bly, The Poplars, Worcester. (Second withheld.)

BANTAMS (Game).—First, R. Liscombe, Tamer Brewery, Devonport. Second, R. H. Nicholas, Yewbery Cottage, Malpas. Third, V. Sandford, Chatsworth Lodge, Mansfield, Plymouth. Highly Commended, V. Sandford; E. Payne, Wharf, Cardiff. Commended, R. Liscombe; R. H. Nicholas. (The whole class meritorious.)

BANTAMS (any other variety).—First, Missa Everett, Gibraltar Cottage, Mermouth. Second, Mrs. A. White, Mannacende, Plymouth. Third, W. Fowell, The Gaer, Newport.

ANY OTHER DISTINCT BREED.—First, A. Heath, Calne, Wilts. Second and Fourth, R. H. Nicholas, Yewbery Cottage, Malpas. Third, T. R. Williams, Dan Rhiw, Maindee, Newport. Highly Commended, J. Hinton, Hiron, near Bath; R. H. Nicholas; J. Buckley, Brown and. Commended, A. Heath; J. Hinton; Mrs. Bly, The Poplars, Worcester.

GUINEA FOWLS.—Prize, Capt. F. T. Parker, Rockfield, Monmouth. *DUCKS* (Aylesbury).—First, J. Richards, Spitty Farm, Aberavenny. Second, J. Logan, the Maindee, Newport. Highly Commended, R. Craw-

shay, Cyfartha Castle, Merthyr; L. A. Homfray, Woodlands, Newport; J. Richards, Spilly Farm, Aberavenny. Commended, W. Powell, the Coar, Newport; Mrs. T. Powell, Colha, Newport; J. Logan.

DUCKS (Rouen).—First, W. Powell, the Coar, Newport. Second, J. H. Brackmidge, Chew Magna, Bristol. Highly Commended, Miss L. Crawshaw, Caver-ham Park. Commended, R. Crawshaw, Cyfartha Castle, Merthyr; J. H. Brackmidge; Rev. H. G. Darby, Swinton, Wilt. **GREYS.—**First and Second, E. Hres, Colbrook Cottage, Aberavenny. Highly Commended, A. Cathbertson, Cefnullech, Llangibby. Commended, Miss L. Crawshaw, Caver-ham Park, Reading.

FURZEYS.—First, Miss J. Milward, Newton St. Loe, Bath. Second, W. P. Hawkins, Pontymelle House, Pontypool. Third, Capt. Commended, W. Crawshaw, Ty Torrest, Pontypool; Mrs. E. Everett, Gibraltar Cottage, Monmouth. Commended, C. Lyne, Brythyrhyd, Newport; R. Crawshaw, Cyfartha Castle, Merthyr.

ANY NEW VARIETY OF DUCKS, GREYS, OR TURKEYS.—First, J. Martin, Claines, Worcester. Second, Miss H. Day, the Poppars, Worcester. Commended, Miss J. Milward, Newton St. Loe, Bath.

SPANISH COCK.—Prize, J. Parsons, Menasteg, Bridgend. Highly Commended, J. Carr, Hafod, Swansea; Mrs. C. A. Lewis, Glyn Pedr, Crick-horke.

DORKING COCK.—Prize, R. Crawshaw, Cyfartha Castle, Merthyr. Highly Commended, R. Everett, Gibraltar Cottage, Monmouth; J. Logan, the Maidne, Newport. Commended, Capt. E. T. Parker, Fockfield, Mummouth.

GAME COCK.—Prize, J. Martin, Claines, Worcester. Highly Commended, W. Crawshaw, Ty Torrest, Pontypool. Commended, C. P. Betts, Newport.

COTTAGEES' PRIZES.

ANY DISTINCT BREED OF FOWLS.—First, W. Attwells, Malpas, Newport. Second, Third, and Fourth, Miss M. Pillingier, Malpas, Newport. Fifth, C. Ray, Bissill, Newport.

ANY DISTINCT BREED OF DUCKS.—First and Second, W. Attwells, Malpas, Newport.

Judge, Charles Ballance, Esq., 5, Mount Terrace, Taunton.

KENDAL POULTRY SHOW.

DECEMBER 19TH—21ST.

THE Show just closed, at the Shakspeare Assembly Room, Kendal, is the seventh Meeting of this Society. On all the previous occasions the Kendal Shows have held a high place in the esteem of poultry amateurs; and, although the Birmingham, Crystal Palace, and the Manchester Shows this year have taken place so rapidly upon each other, and closely about the time of the Kendal Show, still that Committee may well congratulate themselves on finding their Meeting for 1871 has improved rather than deteriorated.

On entering the Exhibition, Black Spanish were the variety that first met the eye of visitors, and a goodly array were mustered as we have seen at any local shows for many years past. It will form no matter of surprise to find that Mr. Henry Lane, of Milk Street, Bristol, took precedence with his so-frequently-successful pen of adults; Mr. Fowler, of Aylesbury, proving a very good second; and the third prize was secured by Mr. Teaboy's well-known pen of last year. The ravages of time however, tell not less powerfully on poultry than on ourselves—the unapproachable old cock, that for the two last seasons was the coveted one of all others by our principal Spanish breeders, is now become a mere wreck of former days. Blud with age, and grown listless from infirmity, he still stood highly as an attraction for his former exploits, and many were the remarks we heard made expressive of astonishment at the extraordinary change just described. The bird stood motionless for hours together, and even when touched quickly lapsed into his former dulness. On the best authority we are informed, that within twelve months' past thirty-five guineas were offered to, and refused for this one bird only, by the breeder of it, Mr. Teaboy; that gentleman still evincing great interest and sympathy in its welfare for his past good deeds. Perhaps there is not any fowl still living that has taken so many Silver Cups and first prizes as this old favourite; but the days of triumph are to him a bygone. The Spanish Silver Cup, however, open for competition by either old or young birds, was well won by a son of this veteran prize-taker, accompanied by two pullets of great merit—a fact easily imagined, when on reference to the prize list it will be found the celebrated strain of Mr. Rodbard, could only hold a second place.

In Dorkings the Show stood exceedingly well. A pen of Silver Greys, belonging to Mr. Rutledge, of Kendal, obtained the Silver Cup; they were adults, and were shown in a most praiseworthy condition. Mr. Seddon, of Prescot, and Mr. Dolby, of Gratham, had a hard pull for the mastery in the Dorking chickens.

In Cocksins the Bulls and Dark-feathered ones all competed in one general class. Mr. Elijah Smith, of Manchester, gained the Silver Cup for Cocksins with a pen of Partridge-feathered ones; Mr. Copple, of Prescot, pressing hard with a first-rate pen of Bulls. Mr. Stretch's pen of Buff chickens were deservedly at the head of their class.

In the Game classes the Show stood a perfect success. It was a certainty, however, that the Brown Reds were the best feathered, and, consequently, swept the board of the principal premiums—in fact, both the Silver Cups for Game were taken by this variety. It is somewhat singular that the White Game completely left behind the Pile birds—a circumstance of very rare occurrence where the competition is general between them.

It is difficult to assign a reason for such being the case, yet it is certain that the various classes for *Hamburgs* and *Polands* presented the weakest amount of entries we can call to recollection. This falling off is a matter for regret, as unquestionably these slow varieties are always among the favourites of visitors.

Again, in *Bantams*, not a solitary bird of either coloured or White was exhibited, and the entry for both Blacks and Whites was also meagre; but the Game Bantams made ample amends, for they formed a principal feature of the Show. We must draw especial attention to the Duckings of the Hon. Secretary, Mr. Whitwell; they are gems, whether for size or purity of colour.

The Aylesbury Ducks were very good, and Mr. Fowler as might be expected stood 1st; but it remained for the Rouen class to prove the closest competition on record. Out of twelve pens, all perfect in feather and condition, only bare three-quarters of a pound existed in the most opposed weights. Again, between the silver-cup pen and second-prize scarcely two ounces drew the balance in favour. In the "any variety" class for Ducks, Mr. Earle, of Prescot, and Mr. G. S. Sainsbury, of Devize, exhibited capital pens of Buenos Ayrean, and took relative positions as just named. Mr. Pease, of Darlington, taking third with a pen of very good White Call Ducks.

The Pigeons were good, but the pens for the larger varieties were decidedly too small, and not a few were placed too high above spectators to be easily inspected. An improved arrangement as to these birds in future meetings is determined on.

With this, our shortcoming, it is justice to say, we never remember seeing poultry better or more carefully attended than at Kendal—everything betraying perfect system and order, for whenever wanted the Committee were at their post.

Mr. Edward Hewitt, of Eden Cottage, Birmingham, and Mr. Thomas Challoner, of Whitwell, Chesterfield, were the arbitrators; and we express the opinion of those gentlemen when we say the competition in the Game classes was far beyond precedent in this locality.

SPANISH.—First, H. Lane, Bristol. Second, J. K. Fowler, Aylesbury, Third, R. Teaboy, Fulwood, Preston. Commended, G. Robinson, *Chickens*.—Cup, R. Teaboy. Second, J. R. Rodbard, Bristol. Third, E. Brown, Sheffield. Highly Commended, H. Lane, J. K. Fowler. Commended, J. P. Harrison, Kendal; F. Crook, Harrington Street, London.

DORKINGS (Coloured or White).—Silver Cup, W. W. Rutledge, Kendal. Second, J. Robinson, Garstang. Third, W. Seddon, Prescot. Third, Highly Commended, H. W. B. Bervick, Helmley. Commended, J. Shortless, Newcastle-on-Tyne; W. Dolby, jun., Gratham. *Chickens*.—First, W. Seddon, Prescot. Second, W. Dolby, jun. Third, W. W. Rutledge. Highly Commended, W. Copple, Prescot. Commended, Rev. J. F. Newton, Kirkby-in-Cleveland.

COCKSINS CHICKENS (Cinnamon and Buff, or Brown and Partridge-feathered).—Silver Cup, E. Smith, Manchester. Second, W. Copple, Prescot. Highly Commended, T. Stretch, Liverpool; J. Shortness, Newcastle-on-Tyne; W. Copple; J. Bell, Kirkgate, Thirk. Commended, H. Tomlinson, Birmingham. *Chickens*.—First, T. Stretch. Second, H. Tomlinson. Commended, W. Jackson, Bolton-le-Sands. Miss V. G. Musgrove, Ormskirk. Commended, E. A. Aglionby, Wigton; A. Worthington, Bolton-le-Sands. **COURTIN CHICKEN (White or Black).—**Second, C. C. Whitwell, Kendal. (First withheld). *Chickens*.—First, W. Copple, Prescot. Second, G. C. Whield. Commended, R. Loff, Woodmansey; G. Williamson, Nantwich.

GAME FOWLS (White and Piles).—First and Second, G. C. Whitwell, Third, F. Atkinson, Milnthorpe. *Chickens*.—First, W. Wilkinson, Whitbirtle. Second, G. C. Whitwell. Third, J. Clarke, Levens, Milnthorpe. Highly Commended, G. Hellwell, Sheffield. Commended, J. Clarke.

GAME FOWLS (Black-necked and other Reds).—First, N. Grimshaw, Pendle Forest, Bailrey. Second, G. Hellwell, Sheffield. Third, J. Hindson, Liverpool. Highly Commended, R. Swift, Southwell. Commended, J. Fletcher, Manchester. *Chickens*.—Silver Cup, G. Hellwell, Sheffield. Second, E. Aikwood, Darlington. Third, G. C. Whitwell, Kendal. Highly Commended, J. Heath, Nantwich; A. B. Dyas, Maudley; W. Bentley, Low Moor, Yorkshire; R. I. Robinson, Uverston. Commended, M. Graham, Kendal.

GAME FOWLS (any other variety).—First, J. Hindson, Liverpool. Second, G. C. Whitwell, Kendal. Third, W. Brocklebank, Uverston. Commended, W. Thompson, Kendal. *Chickens*.—First, R. Bateman, Kendal. Second, W. Bentley, Low Moor, Yorkshire. Third, J. Barrow, jun., Kendal. Commended, W. W. B. Bervick, Helmley.

HAMBURG Golden-pencilled.—First, J. Robinson, Garstang. Second, R. R. Tulip, Monkwearmouth. *Chickens*.—First, T. Parkinson, Accrington. Second, T. Shaw, Kirkham. Highly Commended, R. I. Robinson, Uverston.

HAMBURG (Golden-spangled).—*Chickens*.—First, J. Cragg, Kendal. Second, K. Graveson, Kendal.

HAMBURG (Silver-pencilled).—*Chickens*.—First, C. Moore, Preston. (Second prize withheld).

HAMBURG (Silver-spangled).—First, R. Teeby, Fulwood. Second prize withheld. *Chickens*.—First, B. Beard, Kendal. Second, W. Whitwell, Stockton-on-Tees.

POLANDS (any variety).—First, H. Johnson, West Sunderland. Second, J. Heath, Nantwich. *Chickens*.—First, G. Pease, Darlington.

PRIZES FOR SINGLE COCKS.

SPANISH COCK.—First, G. Robinson, Kendal. Second, R. Teeby, Fulwood, Preston.

DORKING COCK.—First, D. Steel, Windermere. Second, W. Seldon, Prescott. Highly Commended, D. Hetherington, Penrith; J. Robinson, Garsburg.

COCHIN-CHINA COCK.—First, W. Seldon, Prescott. Second, R. Farrer, Bolton. Highly Commended, F. Smith, Manchester. Commended, T. Ransford, Hey, W. Musgrove, Aylesbury, Oxford.

GAME COCK.—First, G. Hellivich, Sheff.-H. Second, T. Burgess, Whitclureh, Nidrop. Third, J. Fletcher, Stoneclough. Fourth, N. Grimshaw, Burnley. Highly Commended, Mrs. Bateman, Sedgwick; C. Moore, Preston; J. S. Butler, Poulton-le-Fylde; G. Lingard, jun., Birmingham; J. Pearson, Liverpool. Commended, J. Heath, Nantwich. *Cockerels*.—First, S. Butler, Poulton-le-Fylde. Second, G. C. Whitwell, Kendal. Third, M. E. Ellithorpe, Kendal. Commended, J. Orr, Cartmel, Lancashire.

GAME BANTAM COCK.—First, Miss V. W. Musgrove, Ormskirk. Second, J. H. Highley, Preston. Commended, C. Bower, Poulton-le-Sandis; Mrs. Cragg, Kendal; G. C. Whitwell, Kendal. Commended, J. Mashiter, Ulverston.

BANTAMS (Game).—First, G. C. Whitwell, Kendal. Second, E. Holdsworth, Leeds. Highly Commended, J. Grosset, Nantwich; J. Mashiter, Ulverston; Miss V. W. Musgrove, Ormskirk.

BANTAMS (Any other variety).—First, G. Bentley, Leeds. Second, E. Holdsworth, Leeds.

DUCKS (Aylesbury).—First, J. K. Fowler, Aylesbury. Second, G. Pease, Darlington. Third, J. G. Gray, Nantwich. Commended, R. Tate, Driffield.

DUCKS (Bouvier).—First, W. Seldon, Prescott. Second, W. Cople, Preston. Third, J. Sargenson, Garry, Kirby-Lonsdale. Third, W. Mitchell, Keighly. Highly Commended, W. Willison, Kendal; R. Tate, Driffield; J. K. Fowler, Aylsburry; R. I. Robinson, Ulverston. Commended, A. Worthington, Bolton-le-Sands.

DUCKS (Any other variety).—First, F. W. Earle, Edenbast, Prescott. Second, G. S. Sainsbury, Rowle, Pezizes. Third, G. Pease, Darlington. Highly Commended, Mrs. T. Hodgson, Carnforth.

FACONS.—*Carriers*.—First, J. Shortluse, S. field Hill Green, Newcastle-on-Tyne. Second, T. Kew, Burton-le-Kendal. Highly Commended, I. Monkhouse, Kendal; D. Thwaites, Rock Ferry, Cheshire. *Amoud Tumblers*.—First, W. Cannon, Bradford. Second, A. L. Silvester, Birmingham. *Tumbler* (any other breed).—First, W. Cannon, Bradford. Second, I. Monkhouse, Kendal. Highly Commended, Mrs. A. Monkhouse, Kendal. *Owls*.—First, W. Cannon, Bradford. Second, D. Thwaites, Rock Ferry, Cheshire. Highly Commended, I. Monkhouse, Kendal; D. Thwaites, Rock Ferry, Cheshire; A. L. Silvester, Birmingham; L. Smith, Birmingham.

Foxes or Croppers.—First, E. Brown, Sheffield. Second, T. Hodgson, Carnforth. Highly Commended, D. Thwaites, Rock Ferry, Cheshire. Commended, D. Thwaites, Rock Ferry, Cheshire. *Darbs*.—First, E. A. Hargrove, Birmingham. Second, W. Cannon, Bradford. Highly Commended, G. Gore, Liverpool; A. L. Silves or, Birmingham. *Keatles*.—First, F. E. Earle, Bayswater. Second, J. W. Edge, Aston New Town. Highly Commended, W. Elphinstone, Woodmansey. Commended, G. Gore, Liverpool; H. Yardley, Birmingham. *Turbits*.—First, F. E. Earle, Bayswater. Second, E. A. Hargrove, Birmingham. Commended, E. Brown, Sheffield. *Trunspeters*.—First, F. Key, Beverley. Second, D. Thwaites, Rock Ferry, Cheshire. Highly Commended, D. Thwaites, Rock Ferry, Cheshire; E. Smith, Birmingham. W. Cannon, Bradford. *Cochins*.—First, W. Cannon, Bradford. Second, F. E. Earle, Bayswater; J. W. Edge, Aston New Town; E. Brown, Sheffield; W. Cannon, Bradford. Commended, H. Yardley, Birmingham; F. E. Earle, Birmingham. *Any other variety*.—First, J. Barrow, jun., Kendal (Magpies). Second, A. L. Silvester, Birmingham (Spots). Highly Commended, E. A. Hargrove, Birmingham (Fringlbacks) and E. Smith, Birmingham (Fringlbacks). Commended, E. Smith, Birmingham (Nuns).

EXTRA SPOCK.—Highly Commended, J. Hespik, St. Catherine, Windermere (Dorkings); J. Hulley, jun., Kendal (Brown-red Game Cockerel); G. C. Whitwell, Kendal (White Cochon Pallees, Dorking Pallees, and Dorking Itens). Commended, H. Cragg (Golden-spangled Hamburg).

were passed over without notice. The *Polands* we thought nothing particular. The "variety class" brought Malays, Cuckoos, Brahmas, Black Hamburgs, &c. Mr. Tate taking first with a pen of the first-named variety, which were claimed at 30s. In the class for *Grinea Fowls*, Mr. Tate took first, with a pen of Greys; a pair of Whites in the moult coming in third. The *Bantam* classes contained some good birds. The first prize for Game Bantams was gained by Mr. J. Crossland, jun., the (alleged) second-prize pen at Darlington being passed over without notice.

Turkeys, Geese, and Ducks were well represented. The first-prize pen of *Geese* were excellent.

The following is the award of prizes:—

DORKINGS (any colour).—First, J. Dixon, Bradford. Second, H. Himsforth, Wakefield. Third, T. E. Kell, Wetherby.

SPANISH.—First, J. Dixon. Second, E. Smith, Manchester. Third, J. Davis, Highly Commended, T. B. Stead.

COCHIN-CHINA.—First, T. E. Seal. Second, E. Smith. Third, J. Dixon. Highly Commended, J. Bell, Thirsk.

GAME (Black-breasted and other Reds).—First, Miss E. Beldon, Bradford. Second, H. Adams, Beverley. Third, J. Firth, Halifax. Highly Commended, H. M. Julian, Beverley; T. Dadds, Halifax. Commended, R. Hemingway, Halifax; J. Hodgson, Rowling Old Lane.

GAME (White and Pile).—First, H. Mason, Drighlington. Second, H. Adams. Third, J. Crossland, jun., Wakefield. Highly Commended, R. Hemingway, Shelf. Commended, T. Dadds.

GAME (any other variety).—First, H. Adams. Second, J. Firth, Halifax. Third, H. Adams. Highly Commended, T. Dadds.

HAMBURG (Gold-spangled).—First, F. Hardy, Laister Dyke. Second, J. Dixon. Third, F. Hardy. Highly Commended, T. W. Hill, Manchester; H. Pickles, Skipton. Commended, Miss E. Beldon.

HAMBURG (Silver-spangled).—First, J. Dixon, Bradford. Second, Miss E. Beldon, Bradford. Third, W. Simpson, Dunswick.

HAMBURG (Gold-spangled).—First, S. Barrett, Harewood. Second, W. Lawson, Otley. Third, J. Dixon. Highly Commended, Farnhill and Rinder, Morley; R. Tate, Driffield; T. H. Turner, Fir View, Sheffield; J. Panforth, Bradford.

HAMBURG (Silver-spangled).—First, S. Ashton, Mottram, Cheshire. Second, E. Smith, Middleton, Manchester; H. Pickles, jun., Earby, near Skipton. Highly Commended, J. Rley, Hawkesworth; S. Barrett.

POLANDS.—First, J. Dixon. Second, Miss E. Beldon. Third, J. Dixon. ANY FANCY CROSS, or other variety, not previously classed.—First, R. Tate. Second, T. M. Brooke, Dewsbury; J. Rinder, Sheepsheer. Highly Commended, J. Dixon; T. W. Hill, Heywood, Manchester; G. Newton, Garforth.

GESE.—*Fowls*.—First, R. Tate. Second, J. T. Fenton, Stapleton House, Bradford. *Newton*.

BANTAMS (Black).—First, J. E. O. Nussey, Wortley, Leeds. Second, A. Farrar, Bramley. Third, G. Bentley, Kirkstall.

BANTAMS (White).—First, J. Dixon. Second, F. Hardy, Laister Dyke. Third, J. Dixon.

BANTAMS (Game).—First, J. Crossland, jun., Wakefield. Second, T. H. Turner, Sheffield. Third, R. Tate, Otley.

BANTAMS (any other variety).—First, E. Hutton, Tadley. *TURBITS*.—First, R. Tate. Second, J. Dixon. Third, J. Radd, Bradford. (The class generally highly commended.)

GESE.—First, R. Tate. Second, J. Dixon. Third, H. Bentley, Outton. (Class highly commended.)

DUCKS (Aylesbury).—First, R. Tate. Second, T. W. Hill, Heywood, Manchester. Third, Farnhill and Rinder, Morley. Highly Commended, T. W. Hill.

DUCKS (Dun or any other).—First and Second, J. Dixon. Third, W. Sissons, Preston Hall. Highly Commended, J. Rhodes, Drighlington, and W. Ingham, Armley.

EXTRA POLTRY.—J. Dixon. Second, John Sunderland. Third, E. Beldon.

The Judges were Mr. E. Bond, of Leeds; Mr. Smith, of Halifax; and Mr. J. Hindson, of Liverpool.

LEEDS POULTRY SHOW.

The second annual Exhibition of poultry in connection with the Leeds "Smithfield Club," was held conjointly with the show of fat stock, in the Smithfield Market Place, Leeds, on the 10th and 11th inst., in a commodious, well-lighted, wooden building erected for the purpose. The prize list for poultry was devised on a liberal scale, and a silver cup in addition to the first prize was offered for the best pen of poultry in the Show.

The entries in all numbered 261 pens, and the birds shown were excellent. *Dorkings* of any variety headed the list, and Mr. Jas. Dixon took first prize and silver cup, for the best pen in the Show, with a good pen of Coloured. The *Spanish* were not remarkable, most of the cocks shown had combs inclined to hang over. *Cochin-Chinas* of any colour came next, Mr. T. B. Stead winning with a heavy pen of Partridge. In Black-breasted Red Game, Miss Beldon took first prize; and in Whites and Piles Mr. Mason won with a beautiful pen of Whites, considered by many to be the best pen of birds in the Show. In the "variety class" for Game, we should not forget to mention the Duckings of Mr. Adams, who deservedly took two of the prizes. The *Hamburgs* shown were of particularly good quality especially the Golden-spangled; but several really excellent pens

CHIPPENHAM POULTRY EXHIBITION.

The annual Exhibition of poultry in connection with the Chippenham Agricultural Society, was held in that town on the 12th and 13th inst., and, without doubt, it was by far the best collection of the feathered tribe ever gathered together in their spacious market-yard, which may be attributed to a better classification of the prize list than on any former occasion.

The first class on the list was the *Dorkings*, and in it were several good pens; but we could not quite see what entitled Mr. Hanks' pen to rank first, as both the cock and one of the hens had deformed feet, and we thought both the second prize and highly commended were larger. In *Spanish*, Mr. Rodbard stood first, and we preferred Mr. Brinkworth's commended to Mr. Heath's second-prize pen, as their faces were much cleaner as well as larger, and they were in far better condition. In *Game* the Black-breasted Reds formed an excellent class, the competition being exceedingly sharp. *Cochins* mustered only three pens, which called for no special mention. In *Hamburgs*, although there was not a numerous entry, all three varieties represented were good; but, strange to say, there was not a single pen of Silver-spangled. Mr. Keable's Silver-pencilled, and Messrs. Wiltshire and Baily's Gold-spangled well deserved their honours.

In the "variety class," Mr. Heath stood first with a fine pen of Single-comb light *Brahmas*. It is a remarkable fact, but Game *Bantams* were represented by one pen only, and that a very ordinary lot of Duckings. In the other Bantam class the first prize went to some good Blacks, the second to a pen of White Bantam.

Miss Milward's first-prize *Turkeys* were exceedingly good.

The *Geese* also were meritorious.

We have seen the *Aylesbury Ducks* much better; but Rouens made amends, forming an excellent class. This year the Committee acceded to a request made to them, and added a third class for Ducks, which was supported as well as any other in the Show. Mr. Sainsbury taking first with an excellent pen of East Indian, and but for a rule prohibiting any exhibitor taking both prizes in a class, we have little doubt he would have taken second also, consequently it went to a pen of White Calls.

The *Game Cock* sweepstakes was well contested, the first prize going to a smart bird of Mr. Lamb's, while the whole class was pronounced by the Judge to be very superior.

DORKINGS—First, Miss Hanks, Malmesbury. Second, Miss Milward, Newton St. Loc. Highly commended, T. Keeble, Lambourne.

SPANISH—First, J. K. Goddard, Aldwick Court. Second, A. Heath, Calne. Commended, O. Brinkworth, Calne.

GAMB (Black-breasted and other Reds.)—First, G. Hanks, Malmesbury. Second, Hon. G. Howard, Charlton. Third, — Elling, Sutton Parva. Highly commended, R. Stratton, Birkworth. Commended, — Wentworth, Hightworth. — Lamb, Hightworth.

GAME (any other variety).—First, W. Bleadon, Calne. Second, — Elling, Sutton Parva. Highly commended, F. Baily, Calne.

COCHIN-CHINA (any variety).—First, A. Heath, Calne. Second, G. Hanks, Malmesbury.

HAMBURGERS (Gold-pencilled).—First, E. Phillips, Chippenham. Second, J. Orledge, Chippenham. Commended, E. Phillips, Chippenham.

HAMBURGERS (Silver-pencilled).—First, Miss K. Abbe, Lambourne. Second, W. Bennett, Cromhall. Third, T. Keeble, Lambourne.

HAMBURGERS (Gold-spangled).—First, L. Wiltshire, Calne. Second, F. Baily, Calne.

ANY OTHER DISTINCT OR CROSS-BREED.—First, A. Heath, Calne. Second, T. Smith, Westbury. Third, Miss Milward, Newton St. Loc.

BANTAMS (Game).—First, A. Heath, Calne.

BANTAMS (any other variety).—First, R. Brotherhood, Jan., Chippenham. Second, H. Cox, Chippenham.

TURKEYS.—First, Miss Milward, Newton St. Loc. Second, E. P. Sly, Westbury.

GEESE.—First, R. P. Rich, Chippenham. Second, G. Hanks, Malmesbury. Commended, Mrs. Bridges, Dauntsey.

DUCKS (Aylesbury).—First, T. Smith, Westbury. Second, G. Hanks, Malmesbury. Commended, J. W. Brown, Uffcot.

DUCKS (Rouen).—First, T. R. Halbert, Badington. Second, Hon. G. Howard, Charlton. Third, — Elling, Sutton Parva.

DUCKS (any other variety).—First, G. S. Sainsbury, Rowde. Second, P. Awley, Chippenham. Highly commended, G. S. Sainsbury, Rowde. Commended, G. S. Sainsbury, Rowde.

SWEETFARES for the BEST GAME COCK.—Prize, — Lamb, Hightworth. (A very superior class of birds.)

EXTRA CLASS.—Bounties were given to Mr. Elling, Sutton Parva; Mr. W. Awley, Chippenham; Miss Milward, Newton St. Loc.

The Judge was G. J. Andrews, Esq., of Dorchester.

THE SALES OF POULTRY AT THE LATE BINGLEY HALL SHOW.

We have extracted the following particulars from the return of sales at the late Exhibition, in the hope of their being found interesting to the large class of persons whose tastes or pursuits lead them to keep an eye on quotations of the live bird market. The four days' transactions at Bingley Hall, were as follows:—

	No. of pens sold.	Amount realised.		Average price per pen.
		£ s. d.	£ s. d.	
Monday.....	115	479 14 0	4 3 6	
Tuesday.....	38	123 0 6	3 5 0	
Wednesday.....	12	42 9 0	3 19 0	
Thursday.....	21	59 17 6	2 17 6	
Total.....	186	705 1 0	3 15 0	

It will be observed, from these figures, that the first day is the one on which operations are most numerous, as well as greatly the most productive. This is probably due in some measure to the class of attendance on that day, though it may be partly ascribed to the desire of amateurs to purchase at the first moment birds which they are specially desirous of obtaining. It shows that buyers should be early in the market if they wish to satisfy a particular taste. The highest price realised was £15, for the first-prize pen of Spanish chickens. Next came £12 12s., given for the cup pen of Black-breasted Neck Game birds. £12, the highest amount of next degree, went for the third-prize Buff Cochins. Four amounts of ten guineas each were given for the following pens—first-prize Silver Grey

Dorkings; Mr. Dawson's pen of Game fowl (No. 819) which obtained neither prize nor commendation; first-prize Golden Pheasants; and first-prize Silver-spangled Hamburg chickens. The first-prize Buff Cochins chickens formed the only pen which realised exactly £10. Six pens fetched from £8 8s. to £8 10s. They were the second-prize Dorking hens, first-prize Dorking pullets, first-prize Game Bantams, first-prize White Aylesbury Ducks, commended Dorking pullets, and highly commended Coloured Dorking chickens. Prices of £7 and £7 10s. each were realised by the three pens of first-prize Silver-spangled Hamburgs, third prize ditto, and first-prize Polish Single cock. Sums ranging from £6 to £6 10s. are returned for eight pens—namely, first-prize Game Bantams (Black-breasted), commended White Cochins chickens, commended Black-breasted Game Single cock, second-prize White Aylesbury Ducks, two pens of highly commended Coloured Dorking chickens, first-prize Brown Game chickens, and second-prize Dorking pullets. These are all the particulars that need be quoted by way of illustrating the highest range of prices. The following is a summary of the number of pens sold at each rate of quotation:—

	Price.		No. of Pens sold.
	£ s. d.	£ s. d.	
From 12 0 0 to 15 0 0	3
" 10 0 0 " 10 10 0	5
" 8 8 0 " 8 10 0	7
" 7 0 0 " 7 10 0	3
" 6 0 0 " 6 10 0	3
" 5 0 0 " 5 5 0	23
" 4 0 0 " 4 10 0	20
" 3 0 0 " 3 10 0	35
" 2 0 0 " 2 10 0	41
" 1 0 0 " 1 17 6	53

Total pens sold..... 186

Persons desirous of purchasing true-bred fowls at reasonable prices seem, from this statement, to have every prospect of meeting with success at the Bingley Hall collection, for it will be observed that only 41 pens out of 186 were 1d for so much as £5 each.

The following is a statement of the number of pens sold and amount realised in each class of the Exhibition:—

	No. of Amount			No. of Amount	
	Pens sold.	Realised.		Pens sold.	Realised.
Dorkings.....	59	211 19 0	Swans.....	1	2 0 0
Cochins.....	16	68 17 0	Geese.....	8	25 1 0
Game.....	32	118 18 6	Ducks.....	14	54 4 6
Hamburgs.....	25	98 15 6	Turkeys.....	4	17 3 0
Brahma Pootra.....	4	10 5 0	Pheasants.....	2	12 0 0
Polish.....	3	12 14 0	Pigeons.....	4	13 5 0
Spanish.....	4	25 19 0	Single cocks.....	27	87 8 6
Bantams.....	11	39 18 0			

The Dorkings here take a decisive lead, as it is the opinion of many practical judges that they ought to do, since they seem on the whole the best adapted of all classes to meet the several uses for which poultry is kept. The Spanish breed carried away the highest price given for a single pen, though the amounts of next degree were pretty equally scattered among the various divisions.

Comparing the sales with the prize awards, we find the results to be as follows:—

Number of prize pens sold.....	58
Number of commended ditto.....	43
Other pens.....	85

Total..... 186
— (Birmingham Times.)

QUANTITY OF FOOD FOWLS REQUIRE.

Will you inform me how long a bushel of barley and a peck of barley-meal, with a grass run of about three acres, ought to last twenty fowls, so as to feed them well, but not so well as to make them too fat to be good layers? The sorts are Dorking and half-bred Dorkings, and Cochins.—AN AMATEUR BEGINNER.

[Our answer cannot be specific, it must be a general one. Fowls do not always eat the same quantity. They vary according to weather, season, condition, and previous feeding. In frost they eat more, as the surface of the earth produces nothing. In the summer, herbage helps them very much; and when they have always been well fed, they consume less than when they have been kept on short commons.]

The exp-ense of keeping fowls is caused by waste, and whenever any food is seen on the ground there is waste. Fowls should be fed by hand, and food should be given only so long as the birds run after it. All after that is thrown away.]

BANTAM CLASSES AT THE CRYSTAL PALACE POULTRY SHOW.

WILL Mr. Houghton forgive me for suggesting that the Game Bantam classes at the Crystal Palace Show be in future divided into "Black-breasted and other Reds," and "Duckwings and any other colour?" On reference to the catalogue of the Show held December 11th, it will be seen that in this class there were twenty-three entries, whilst in the two classes, "Black," and "White," there were but thirteen altogether, and in the Gold and Silver Sibrighit classes but twenty-one. It is true there were three prizes in the Game Bantam class, and two only in the others; but I feel sure it would be more satisfactory to exhibitors if the colours were divided in some such way as suggested, and the prizes made like those in other classes. Mr. Houghton has shown every disposition to meet the wishes of exhibitors, and I think he will consider what I have stated worth consideration before preparing his next schedule.—P.

HONEY AND CHEMISTRY.

ALLUSION has been made by some of your correspondents, and, I think, among them, "A DEVONSHIRE BEE-KEEPER," to some supposed chemical change effected by the bees in their food, whether collected from flowers or artificially supplied, and which has led to a remark in "A RENFREWSHIRE BEE-KEEPER'S" last letter, who evidently disbelieves is anything of the kind, and in which I am inclined to join him. The short time in which the secretion from flowers, or the substitutes for it, are retained in the honey-bags of the bees, precludes the possibility of any change being made at the time of collection, and there is no proof that any subsequent alteration takes place, except what may be accounted for in another way. Dr. Bevan remarks (page 253), "In the 'Philosophical Transactions' for 1792, Mr. Hunter stated, that whatever time the contents of the honey-bags may be retained, they still remain pure and unaltered by the digestive process. Mr. Polhill is also of this opinion. Messrs. Kirby & Spence think that as the nectar of flowers is not of so thick a consistence as honey, it must undergo some change in the stomach of the bee." So also argues the redoubtable Huish. "But," continues Dr. Bevan, "the naturalists just named are not borne out either by my own experiments or those of my apianian correspondents. We have each tried supplying bees with syrup of sugar as a resource for winter, without finding any material change after it was stored." This, also, is my experience; and if honey is a chemical or elaborated substance, why is it not always alike? The whole mystery is, I think, solved by atmospheric influence acting upon an original saccharine, at first very fluid, but hardening and thickening in an altered temperature, like any other conserve or syrup natural or artificial. This was the opinion of Dr. W. Dunbar, no superficial observer, who says, that the conclusions of Kirby & Spence were not confirmed by any experiments of their own.

It is with fear and trembling I approach another subject on which "A RENFREWSHIRE BEE-KEEPER" appears to be very sensitive—viz, as to the common results of "super-posing." It is very likely he may be right under certain circumstances as to peculiarity of hive, &c.; but the more general rule, so far as I have seen and read such authors as Bevan, Dunbar, and Goding, is in favour of the theory that bees prefer to breed in the lower portion of a hive, and carry their store into that part the farthest from the entrance, frequently partially removing it downwards subsequently. In other words, the lowest is the stock in common cases, for as Dr. Bevan says, "the queen is generally more disposed to descend than to ascend." It is well it should be so, as otherwise the distance from a supply of pure air might cause an increase of damp, leading to disease, and especially dysentery, under the confinement of winter, as I know to my cost. Indeed this would seem to have been the case with your correspondent, who found that his "little favourites, sore pressed by long confinement during frost, converted the lower compartment to a necessitous purpose."—A. B.

BEEES AND THE ART OF QUEEN-MAKING.

(Continued from page 206.)

In the former article on this subject we noticed divers very obvious errors, which induced us to question whether the Rev. Principal Leitch had brought his whole powers of observation

to bear on apianian subjects, and adduced one or two circumstances which made us doubt whether his theory of a special temperature, however plausible it might appear, could be accepted as the true solution of one of the most extraordinary of Nature's mysteries, without at any rate better evidence than his author has yet set before us.

We may perhaps admit for the sake of argument, that Dr. Leitch's thermometrical experiments establish the fact of an increased temperature attending the rearing of queens, whether bred in the usual manner or raised from eggs or young larvae, which would otherwise have attained no higher stage of development than that of ordinary working bees: but having granted all this, the question still remains, as we have before hinted, whether the Rev. Principal may not have mistaken effect for cause. Violent muscular exertion is, as we all know, attended by a remarkable increase of animal heat. Friction is also capable of producing an extreme temperature, whilst the sudden compression of atmospheric air will liberate a sufficient amount of caloric to set fire to any readily inflammable substance. Now it appears to us that it would be almost as preposterous to argue that the heat evolved by these various processes was the cause of the processes themselves, as to determine, without much more conclusive evidence than has yet been produced, that the special temperature which is asserted to attend the operation of queen-raising is "the cause," or even "one of the causes which accounts for this the greatest marvel of insect life."

Our own impression is, that the immortal Huber was most probably correct in assigning, as the cause of this wonderful transformation, the quality as well as the quantity of food with which the royal larva is supplied. To this hypothesis Dr. Leitch objects that it has by no means been conclusively proved, either by chemical analysis or by any other means, that the so-called royal jelly differs in any respect from the ordinary food supplied to worker larvae. Whilst freely admitting that this difference may reasonably be held to be open to a doubt, we avow our own conviction founded on almost innumerable opportunities for observation, that it nevertheless exists, whilst it is beyond all question that the quantity of food supplied to an intended queen is greatly in excess of that required for the development of a working bee. This excess is so palpable, that it is frequently possible to determine within a very few hours after the loss of a queen, and before any elongation of the cells has taken place, which of those among the young larvae have been selected as candidates for the sovereignty of the hive, by simply observing the extraordinary quantity of food which has been furnished to the favoured few.

We now come to a circumstance which appears to us so conclusive as to the fact of the food with which it is supplied being the true cause of this marvellous transformation of a worker larva into a queen bee, that we fancy, if it had come under the notice of the Rev. Principal, it would have prevented his promulgating a theory which we believe to be altogether erroneous. The fact to which we allude to is, the power which apianians possess of superseding the functions of the somewhat mythical "council of state," which Dr. Leitch imagines to assemble soon after the discovery of the loss of a queen, the points of whose deliberations are "what plebeian offspring are to be selected, and how many queens are to be reared?" The first hint which we have met with of the apianian being himself able to exercise a right of choice in this matter, occurs in M. Hermann's little book, in which we find it stated, that "if a piece of about an inch square is cut off, crossways, from below the edge of a young brood-comb full of grub eggs, so that the liquid of the young runs out, it generally causes the bees to fix their queen cells on that spot in the best order." A much more definite statement than the above, is, however, copied by Mr. Langstroth, from the German *Bienenzeitung*, or Bee-Journal, and is from the pen of the Rev. Mr. Kleins, one of the ablest German apianians:—"Dzierzon recently intimated, that as Huber by introducing some royal jelly into cells containing worker-brood obtained queens, it may be possible to induce bees to construct royal cells where the apianian prefers to have them, by inserting a small portion of royal jelly in cells containing worker larvae! If left to themselves, the bees often so crowd their royal cells together that it is difficult to remove one without fatally injuring the others; as, when such a cell is cut into, the destruction and removal of the larva usually follows. To prevent such losses, I usually proceed as follows:—When I have selected a comb with unsealed brood for rearing queens, I shake or brush off the bees and trim off, if necessary, the empty cells at its margin. I then

take an unsealed royal cell—which usually contains an excess of royal jelly—and remove from it a portion of the jelly, on the point of a knife or pen, and by placing it on the inner margin of any worker-cells, feel confident that the larvae in them will be reared as queens; and as these royal cells are separate, and on the margin of the comb, they can be easily and safely removed. This is another important advance in practical bee-culture, for which we are indebted to the sagacity of Dzierzon."

The foregoing fact appears to us sufficiently conclusive as to the truth of Huber's theory regarding the influence of food in producing the astonishing development of a worker larva into a queen bee, and after giving the whole subject our best consideration, we feel warranted in pronouncing the special temperature theory of the Rev. Principal Leitch to be "Not proven."
—A DEVONSHIRE BEE-KEEPER.

HOW I BECAME AN OXFORDSHIRE BEE-KEEPER.

(Continued from page 60.)

JUNE 14th.—Hived a swarm for Mr. M., and, on my return, I found my old original, age 6, was swarming in a strong east wing so much appreciated by Mr. Kingsley. They had most of them gone over to the park; and, I suppose, my well-known voice had sufficient inducement to win them back again—at any rate they came and settled in the *tanjaue* peas. It was the largest single swarm I ever saw. In the evening, I united them to the swarm and two casts of the previous day; a good join, no fighting, and no queen to be seen dead upon the cloth in the morning, upon which account I watched the hive narrowly all day, thinking, perhaps, that if the queen was still alive, she might prove the means of enticing away her subjects again; but no, all remained, so they performed her funeral rites with silent obsequy, beyond my ken. The hive was so full that I was induced to add a Payne's straw super at once, which they took to, and began working in immediately, though the consequence was, as I never had the circumstance happen before in any of my supers, some bee-bread and brood in the central comb.

15th.—A colt issued at half-past four P.M., from age 3, which was rather too much of a good thing. I did not arrive soon enough to pounce upon the queen as she appeared upon the alighting-lip, but they settled in the peas, and there, after a good hunt and much disturbance, I caught her, and the colt went home. Picked up two dead queens, and two partly alive, crawling languidly on the ground opposite, cast out from age 2, by which I ascertained that they did not intend to throw a colt, and I was right.

17th.—The colt issued again from age 3, and I caught the queen as she came out riding in state on the back of a drone. The bees settled for a short time in a row of potatoes, but they soon came straight to their ancient cells again.

18th.—Once more the colt from age 3, and I secured her majesty as she made her exit; her cavaliers went to the potatoes and then came back again, very angry. Put one of my new breakfast glass supers to this year's colony of the 6th inst., as the hive was becoming very heavy, and I have the glass and its contents by me now; it is one of the most perfect specimens of honey-comb.

19th.—The colt again! Caught the queen, and pressed her too severely between my finger and thumb, or otherwise she did not fancy my retaining her in that cribbed and confined position, for she began to use her sting in a most unmistakable manner, when upon the principle of handling hot iron, I immediately relaxed my grip and away she went; and there comes another, which I also caught, and hallooed for a dessert finger-glass to confine her under, when, lo another! which I caught and placed with her, and two bull-dogs could not have set upon each other more fiercely. The colt settled in the peas where I broke in to find the delinquent queen, which I succeeded in doing and put her also under the glass where the others were still fighting, and a three-cornered duel at once commenced, which ended in the death of all three. I can only compare their fighting to what every Englishman's would be, if our shores were now to become invaded, to put a stop to our progress and our prosperity. Why, every man of us would fight like queen bees—wild beasts! Well, the colt returned again to their home after the loss of their queens, and thus ended its eventful history. A playful attempt at swarming was made by a cast, from age 1,

and it came to nothing; but the clarious blare was there in the evening.

20th.—The cast issued from age 1, they settled in the peas from whence I hived them into an old Payne's, which I call my church-and-state hive; and thereby hangs a tale. The first glass super I ever used, a large concave-sided bell-glass was placed upon it, and the bees worked straight upwards, from the hive to its top, a narrow piece of comb, and then formed two extended limbs, right and left, in representation of a cross. They then added four opposing combs or branches on to the upright limb of the cross, in as just an imitation of a crown that it is possible to conceive in honeycomb. Then they worked intermediate combs; and, when the glass was filled, it still maintained the appearance of a crown, with eight branches in lieu of four; that is why I call it my church-and-state hive and I said, *Esto perpetua!* so I kept that hive by me, and always shall. I thought to unite the above cast to my first new colonised skep in the evening, but it was so full of honey, and its inhabitants were so populous, and working so well in their super, that I thought it advisable not to interrupt them, but to wait for the cast expected from age 6, add that to my church-and-state and let the two casts amuse themselves till the beginning of September, when, I shall cut away their combs entirely in the middle of the day, and unite the bees in the evening to age 1, which is a hive (two swarms and two casts) that I united and purchased last year, from a parishioner, in order to institute in my apiary four stocks in lieu of three, which I formerly wrote was my permanent number. Now, neither those bees nor their ancestors have ever been crossed, but bred in-and-in for years in the cottager's garden, and I find their working powers are by no means equal to my stock, which I always cross by uniting to them a cast or a colt of strangers; new blood from a distant spire; therefore, the cast from my old hive will just effect this purpose, and, I have no doubt, I shall be able to report of renewed vigour from age 1, another year.

The dead queen which I forwarded to you for your inspection, was the only catastrophe that happened in uniting the above casts, and I mention it for the satisfaction of "INVESTIGATOR"—these two casts will yield me, as far as I can judge by the weight of the hive at present, nearly 20 lbs. of run honey at the time mentioned above. Found two dead queens cast out from age 1, and no colt revolves from them.—U. WEALES & OSWALES.

(To be continued.)

OUR LETTER BOX.

SPUR OF DORKING COCKEREL (*Vanquam dormio*).—It is not an uncommon thing for the spur to be on the outside of the leg. We do not mean to say that we do not prefer that the spur should be in its proper place; but the deviation is only a disadvantage and not a disqualification.

TAIL OF GOLDEN-FENCIBLE HAMMER-B COCK (*J. Lindsay*).—The tail should be black, but the edges of the sickle-feathers bronze.

SILVER GREY DORKINGS (*H. E. L.*).—We can only pronounce on what we have seen, and without the least hesitation we say the feather sent to us would be quite sufficient to describe a pen in competition, and, hence, therefore, belong to a Silver Grey. It may be difficult to get the black breast and tail; but they are essentially necessary in the formation of a Silver Grey Dorking. The pens at Birmingham demonstrated the difficulty, but that does not justify any one calling coloured Dorkings Silver Greys. Every one is to excuse for it, because it is rejected on account of a blue can enter freely into the classes where the competition is unrestricted, and they are as valuable for one as the other.

PREPARING FOWLS FOR EXHIBITION (*A Subscriber*).—You must state what breed of fowls you keep, as all do not require the same treatment, some show far plumper, some for symmetry; in some bright colour, in others less, the feathers are wanted. All birds do well on ground-ops mixed with water. None do well if they are fattened. A fattened fowl is only fit for killing. Spanish fowls do better in confinement a few days before exhibiting; but as a rule fowls do better at liberty. In those breeds, however, that are judged by feather it is not always advisable to let them run in dirty weather.

CANARY INFERMEDIC (*Inquirer*).—The "always ruffling its feathers and gaping, besides fluttering its wings and constantly dressing its feathers," is strong evidence that the bird has more company than it desires. There are two kinds of parasites which infest the birds, the other the eggs. Use powdered sulphur in either case among the bird's feathers, moisten the cheeks of the cage with linseed oil, and fill them with powdered sulphur.—E. F.

LIGHTLY QUEENS (*J. L.*).—There is now no means of obtaining Lizarian queens, which, after all, are of very uncertain value. One of the best practical apiculturists we are acquainted with failed with three queens out of four, which he got bred during the last and preceding seasons.

BEES DESERTING HIVES (*A Subscriber*).—Whoever told you that the bees would leave their hives to live on the adjoining common either was loafing about, or doing nothing of the subject.

SKINS OF BIRDS (*K. B., Trbridge*).—Buy the "Taxidermist's Manual." It contains all the information you seek for.

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last thirty-four days, the average highest and lowest temperatures of these days are 44.1° and 31.4° respectively. The greatest heat, 57°, occurred on the 3rd in 1860; and the lowest cold, 4°, on the 2nd in 1854. During the period 143 days were fine, and on 95 rain fell.

THE CLOSE OF THE YEAR.

HE last of anything that has borne to us a measure of enjoyment has about it a tone of melancholy, and holds up a monitory finger. That tone and that finger seem especially conspicuous in the announcement—THIS IS THE LAST DAY OF THE YEAR.

Every journey has its stages—its periods for pause and reflection—and among the stages of Life's journey none is more apt for pause and for thought than the day at which

we have now arrived—there is a shadow upon the day, and the dying year holds up the warning finger. Its days are irrevocable, have they left us wiser, better, happier? For what have we journeyed through them—what has been our prime object? There is but one true reply to that query—happiness. Happiness is the object all strive to attain, and the object is natural—praise-worthy.

The only restriction—but a momentous one—is that the happiness we covet is not to be like the Apples of Sodom, "fair to look upon, sweet to the taste, deadly when partaken of."

Go and study Paton's wonderfully beautiful picture, "The Pursuit of Pleasure," and seek to find if one of the pursuers there portrayed is typical of self. The strivers for honours, for literary fame, for military glory—the sensualist, the drunkard, the miser, are all to be seen there pressing forward to catch and to retain that form of bewitching smiles which floats along, alluring them onwards yet always eluding their grasp—she is never secured by one such as is in that throng.

Yet some there are who do catch Happiness and retain her, and we saw one not long since. Where? "In our mind's eye," and we will trace his outline.

He is a gardener, his family are around him, his income moderate, his love of literature and scientific attainments great, his well-acquired fame widely acknowledged, his friends many, his liberality free, his temper placid, his Christianity practical—he sees God in everything. That man has caught Happiness, and retains her; for she will dwell only with those who strive to have her, not for time, but for eternity.

Once, when talking to that gardener, we spoke in commendation of a divinity author whose work was on his book-shelf, and the concurring assent closed with—"But the best book needs no comments but those which a man may gather from his garden."

That gardener has travelled in many lands—has visited all parts of the British islands—and he coincides with us in thinking that a love of gardening indicates that with it the better part of our nature prevails. "You have heard of the Rev. Henry Ward Beecher," said this gardener, "and I will read you his testimony on this fact—

"SURROUNDINGS INDICATE CHARACTER.

"In the early days, when travelling in the West, it was a matter of some importance and experience to select wisely where I would put up. However, I always looked for flowers, and was seldom misled; for a patch of flowers came to signify kind people, clean beds, and good bread. We all are judged by our surroundings—by appearances. True they are sometimes deceitful, but not always—very rarely so to the man or woman who has been educated to read the heart by the countenance, or calculate the calibre of the brain by the adjuncts of the person—by the *tout ensemble* of the individual. It is not difficult to distinguish the poor rich man from the rich poor man. The manner of discernment is hardly definable. We do it instinctively. The noble mind, the cultivated evergreen heart, is patented—it cannot be counterfeited. We meet men every day whose outline, movements, unconscious expressions, indicate them to be living hypocrites. They are gilt in society and would pass for gold with the new coin, but are detected, and silently and emphatically thrust aside.

"And sometimes this class cultivate flowers—because other people do—because it is fashionable—because the world looks for the beautiful where virtue and wisdom are. But how transparent is this screen to the eye of the really cultivated! The character of the flowers or their arrangement betrays the art and cultivation of their owner. There is no refinement manifest. The abstractly beautiful may be there, but the hand of refinement has not set it in the gold of association. Colours, gaudy and repulsive isolated, are not blended and modified and made beautiful by association with others. The whole picture is a daub—so the educated florist calls it. There must be educated artists in this department of art, as in that lower department, requiring the mixing and arrangement of colours on canvass. And not only must the head be educated, but, first of all, the heart must be taught to respond promptly, sympathisingly, and naturally to the motive of the Creator of the object which it is the office of the artist to study.

"Then it is not so difficult to judge of the character and habits of a family by the single Vine trained at the doorway, or the single plant, transplanted to a wooden box on the door-stone from the prairie or woodland. Whatever it may be, it will in some undefinable way reflect the character of the person who planted it."

Let some of the ladies of Woodstock read that, and learn from it not to discourage flower gardening among their poorer neighbours. He who in the country does not love flowers and their culture is poor, though rich; whilst he who does love them is rich, though he may be poor.

When we conversed with our Nestor gardener at the close of last year, he showed us his diary of what were most worthy of note in the gardening occurrences of the preceding twelve months, and as it is a practice worthy of imitation we will adopt it in the brief space left us to occupy.

The days can never recur in which discoveries revolutionising gardening will be made. We have attained to that elevation of excellence which enables us to cultivate in any given latitude the plants of any other latitude; we can have any flowers, and fruits, and vegetables we covet at any season, however unnatural—we have "Peas in December, ice in June." So we must be content now-a-days with having nothing to jot down as com-

posing the year's harvest of novelties, except a few disconnected fragments.

Foremost in the boons to gardening was the opening of the new Garden in June of the Royal Horticultural Society—an evidence and a pledge of better benefits to be derived by our art from that Institution.

There were introduced but one new Apple worthy of commendation—*Twining's Pippin*, a good late dessert fruit; two new Pears—the *British Queen* and *Steneston*, hardy, richly flavoured, and abundant bearers; thirteen Grapes—*Burchard's Prince*, *Champion Hamburgh Muscat*, *Charon's*, *Early Muscat*, *Gros Colmar*, *Gros Maroc*, *Gros Pense*, *Ingram's Hardy Prolific Muscat*, *Morocco Prince*, *Muscat Noir d'Angers*, *Muscat Troveret*, *Smith's Sweetwater*, and *Stillward's Sweetwater*.

Two new Nectarines, both raised by Mr. Rivers—the *Pine Apple* and the *Victoria*. The latter is a cross between the *Violette Hâive* and *Stanwick*. It does not crack like the latter, is equally delicious, and, as has been well observed, it is "worthily named, for, like our Queen, it has not its equal."

Two new Peaches, also raised by Mr. Rivers—*Early Albert* and *Early Victoria*, "without doubt the best of all the early Peaches."

Two new Pine Apples—the *Hurst House*, or *Fairie's Queen*, and the *Stonleigh Abbey*—the first dwarf and freely fruiting, and the second also excellent, and sustained by a first-class certificate of the Royal Horticultural Society's Fruit Committee, as well as by an award of one of Mr. Dilke's prizes.

Three new Strawberries—*Eclipse*, an excellent early forcer; *La Constante*, late, and a great bearer; and *Marguerite*, richly flavoured, and very large.

Of culinary vegetables we have *Dalmey Sprouts*, differing from the *Brussels* in its sprouts being really small Cabbages; *Fearnought*, a Cabbage which was uninjured last winter in places where all others were killed; and *Parsnip Cervil*, which is really nothing more than the root of *Cherophyllum bulbosum*, ranking "with *Oxalis crenata*, and other such failures, which have from time to time been introduced as 'substitutes' for the Potato."

We can only give the aggregates of the new flowers which have been introduced—namely, of *Auriculas*, 9; *Antirrhinums*, 21; *Azaleas*, 9; *Calceolarias*, 10; *Chrysanthemums*, 26; *Cinerarias*, 20; *Dahlias*, 23; *Fuchsias*, 6; *Geraniums*, bedding, 17; *Glaudiol*, 23; *Gloxinias*, 4; *Hollyhocks*, 29; *Pansies*, 57; *Pelargoniums*, 21; *Pentstemons*, 12; *Petunias*, 5; *Phloxes*, 19; *Picotees*, 8; *Pinks*, 13; *Roses*, 37; and *Verbenas*, 7. Of new plants were introduced 271.*

Having thus enumerated our gains during the past year, let us as briefly cast up the losses we have endured during its days.

In the first month of the year we lost Mr. Beck, the well-known raiser of *Pelargoniums*, and author of "A Packet of Seed-saved by an Old Gardener." In May died Professor Henslow, in whom botany lost a skilled master, and all who knew him, a kind, indefatigable, and trusty friend. July saw Professor Tenore, a still more widely-known botanist, consigned to the grave; and the closing month of the year has taken from us the *Prince Consort*. On this last loss we need not enlarge, for the universal sorrow we have so recently witnessed tells how every native of our islands estimates the consequences of the death of that admirable man, and acknowledges the good which he had originated and maintained. But our noble Queen—no less even in the demonstrations of her love for him taken from her—tells in the following letter how she proposes to foster her memory, and to strive to mitigate the loss which his death occasions to her subjects. The letter is from Sir C. B. Phipps, and was read at a meeting of the Council of the Royal Horticultural Society specially summoned on Friday. The letter was addressed to Mr. Wentworth Dilke, one of the Vice-Presidents:—

"Osborne, Dec. 21, 1861.

"MY DEAR DILKE,—The Queen has directed me to inform you that it is Her Majesty's wish that the Horticultural Gardens should be considered as under her peculiar and personal patronage and protection.

"The only consolation that Her Majesty can hope to find, for the loss of her life, under her bitter and hopeless bereavement is to endeavour to carry out the wishes and intentions of her beloved husband.

"For full particulars concerning all the fruits, flowers, vegetables, and plants we recommend our readers to consult "The Gardener's Year-Book," from which our details are abstracted."

"The Queen well knows the deep interest that He took in this undertaking, and would wish to have periodical reports sent to Her Majesty of the progress and proceedings of the Society,—Sincerely yours,
"C. B. PHIPPS."

Before we again address our readers a new year will have commenced, and heartily do we wish that to every one of them it may be one of many blessings, much instruction, and few sorrows.

"Our worthy friends!—a guide new year
To you, and 'a' your hearts hand dear
At home or far awa!
Though Fortune scripset favours yield,
Hale be your hearts, at home, a-field;
Nor ever lack a cozy bed,
Frae a' the storms that blaw!"

PREPARATORY TREATMENT OF PLANTS FOR CROSS-BREEDING.

THERE is no process of the gardener's art which is better understood by the amateur than that of crossing flowers. Yet, there is not another operation to which a gardener can turn his hand to, about which the great bulk of us gardeners know less of the essentials for success. If I had ten kinds of plants on my list for experiments in crossing next season which I never crossed before, I could hardly find ten men amongst all my acquaintances of whom I could ask advice about the ways I ought to go to work with them; and yet I venture to say, there are not ten men in the country who had ever crossed a flower who would not answer my question without the smallest hesitation. The mere act of crossing flowers is, indeed, the most simple practice in gardening, except pulling up a Groundsel, and then throwing it down where it grew. Simple as these two things are, however, the one of them is yet a problem to be proved, the other a very foolish act.

Who can show me, or prove to himself, the right way to cross *Mangles' Variegated Geranium*? Say, the best way, as if you were asking an editor. But I do not want to know the best way—perhaps the best way would not suit my conveniences for keeping and growing the plants; but if I knew the right way of growing the *Geraniums* for crossing, I would try to adopt it, although I might not be able to practise any but the second or third best way.

Talk about crossing being a simple thing, why to practise it intelligently is at this moment the most difficult question which practical science has to deal with. The work or process of putting a little dust on a given point, which is all that is done in crossing a flower, is simple, as they say; but the art by which the cross-breeder has to prepare his subjects for that very simple operation is just as difficult and as little known as anything under the sun.

The probability is, that every cross-breeder has an art of his own, which he never divulges for fear of being laughed at, or in order that no one else can run the race before him. I have an artful art in the preparation of all my breeders which no one knows but myself. But that is not here or there. The question is about the grand secret and how to get at it—how to prepare *Mangles' Variegated Geranium*, which is all but a botanical mule, and a barren plant in the hands of most people; but it has certainly seeded, and we had the account lately of its having been crossed by the pollen from the shorter stamens of the *Golden Chain*, by Mr. Smith of York; and the question now is, Did Mr. Smith induce this cross by some previous mode of management which was different from the usual run, or was it merely the effect of an accidental circumstance?

My own experience would lead me to believe there is no such thing as an accidental circumstance to cause a plant that is generally barren to bear seeds, whether it was crossed or not. Some plants are most difficult to cross or to hybridise, and temperature seems a main element in the success when they do unite with their fellows, as in cross-breeding, or with very different fellows, as in hybridising one species with another of a different cast and constitution. This is proved when they get plants to cross on the Continent which we cannot manage to cross or even seed here. Here, then, is the first proof before us of an element, or an elementary process, to induce a plant to cross or to bear seeds.

Then, the next question is this, Is temperature alone—that is, a higher temperature, the only means within our reach to cause certain plants to seed or cross, and is that temperature all that

is necessary? Well, it certainly may be all that is required to get the plants to seed, but how about the seedlings? My opinion is, that there is a great deal more importance in the proper soil, and the kind of treatment the plant receives for the previous twelve months before crossing than in temperature. Then, if you could give that soil and that treatment to your plants for twelve months, or twice that number of months in a much better climate, so to describe it, than that of England, my belief is that your seedlings would exceed in value any that could be had in the unassisted climate of England under the best management.

We are all but unanimous that the higher temperature on the continent in summer favours the breeders there, as against our seedlings of the same kinds; and we may rest assured if that be so, that the fact does not stand alone. Other things, we do know, help our processes quite as much as temperature; and why not in this also?

The age and the condition of the mother parent at the time of crossing is, assuredly, of high consideration to the cross-breeder, and I think also to the hybridiser; but of him I am not quite so certain, as for some years past I have done very little at hybridising, although I first began crossing and continued at that branch of it alone for many years. But to this day I am all but at a loss as to the extent of the value of the condition of the male parent at that precise moment. I know to a certainty, however, that if I wanted to have an intermediate cross between a very strong mother—say *Defiance* Scarlet Geranium and by the pollen of such as *Mangles' Variegated* if it had pollen, I should need to prepare *Defiance* by reducing it through ill treatment to a mere scrub or skeleton during the previous season of growth, and to keep it down to that point during the winter and spring following up to the time of flowering for the cross, and the opposite treatment to be given to the weak male, say by taking a two-year-old plant of it in early spring, and with the best compost and treatment to keep it going all that summer without letting it open one bloom the whole season; to have it kindly seen to during that winter and next spring, and to take pollen from a particular truss at midsummer, and from particular flowers of that truss. I say I am quite sure these are safe steps to pursue with two such breeders.

Then I have some reason to suppose, although I have little experience to back me, that if the cross seeds were to be had from a weak parent, by the pollen of *Defiance*, which is very strong, that I should need to reduce *Defiance* just in the same way. What makes me name *Defiance* is, that of all the very strong *Scarlets* it is the most unwilling to seed by the pollen of the medium and the small in stature of its race. But keep it twelve months between starvation and death's door, and it will cross with most of them for an experiment; but it is too coarse in all its parts for profitable breeding. Such a plant as *Mangles' Variegated* Geranium I should suppose would need three seasons of the highest cultivation, with a minimum of stress upon its energy—that is to say, without allowing it to ramble about, as is its natural habit, or to produce one flower the whole time. Then if one undertook to cross it by the pollen of the *Golden Chain*, as has been done by Mr. Smith, I would have the *Golden Chain* invigorated just in the same way as *Mangles'*, or the opposite way to that which would be necessary for *Defiance* for the same purpose. Both the father and mother in Mr. Smith's experiment appear to me to have not been quite up to the point of profitable breeding at the time he crossed them, and that was the real cause of the impossibility of rearing the seedlings, and not the fact of the pollen having been taken from the short stamens.

The prospect and possibility of a hundred trials of the same experiment being made next summer, induced me to write thus at the very beginning of the most busy season for crossing yet on record. Now and during the whole month of January is the right time to give the final potting to all the mothers of all the seedlings which will be worth looking at a second time by the Floral Committee—florists' flowers, bedders, and all hybrids, un-^{less}, indeed, the intended pollen parent is of very weak constitution. In that case I should not think it desirable to pot the much stronger mother sooner than the middle or end of April. Then it would have to be making new roots the whole time it was maturing the crossings, to coin a significant term, and that of itself would be abundantly sufficient to balance the respective powers of both parents.

For all bedding plants which come from crossing, it is of the utmost importance that both parents be of the very same con-

stitutional strength, or as near it as can be had—that both should have been under the highest cultivation the previous year with the above limitation—and that the mother is not wasting her strength in making fresh growth, or new roots, immediately before the crossing is effected and about that time; but from the time the seeds are sure of having "taken," as we say, or past the period at which that kind of plant would cast its pods if they had not been fertilised, I never found that good or bad treatment was of much consequence to the seedlings. I know the very worst treatment of the parent is of no consequence to the seedlings of all Geraniums after they are fertilised twelve or fifteen days.

Although I never crossed for a florist's Pelargonium, nor ever read a word about the way they prepare them for matching, I am satisfied from my knowledge of other sections of the family that the Pelargonium is not much different from the *Scarlets* in this respect—that two-year-old plants make the best mothers—that the mother should not have been much stressed by free-flowering the previous season—that it ought to have all its roots made and finished, and the pot brimfull of them by the end of March or very early in April—that the first truss of bloom is not the best to select flowers for crossing from—that a strong side branch is the best to bear the blooms for crossing—that no more than one truss be allowed to be on one such branch—that no dependance can be placed on the three blooms which generally open first, that is, those from each outside or shoulder of the truss and the very centre one, neither is there much to be expected from the last two or three flowers from the lower or bottom of the truss—that all such flowers are discarded by careful breeders—and lastly, that the plant is stopped carefully from the first day of crossing—also, that all the flowers to be crossed on one plant should be done as nearly at the same time as is practicable.

At all events the foregoing have been my grand secrets, and of the value of any one of them I have not the smallest doubt—they are all essential to good breeding. D. BEATON.

CULTURE OF THE VINE IN THE ORCHARD-HOUSE.

THE term "orchard-house" means simply a plot of land planted with the usual orchard trees, and covered with glass. The idea may be carried out to any extent by adopting the ridge-and-furrow roof supported by cast-iron pillars. I observe orchard-houses are being built in various parts of the country, and, therefore, the system or mode is having a fair and somewhat extensive trial.

No doubt in some cases there may be failures through want of good judgment and proper management, and, I may add, experience. Its most strenuous and most successful advocate is Mr. Thomas Rivers, of Sawbridgeworth, ably seconded by Mr. Pearson, of Chilwell, near Nottingham. Both these gentlemen have written on the subject, and have been successful in producing crops of good fruit in their orchard-houses. I have for many years been recommending all Peach-walls to be covered with glass; for the failure of the crops has of late years been the general rule. Indeed, good fruit from open walls is rarely obtained.

The original idea on this subject was to merely protect the fruit trees from early and late frosts by covering them with glass in the roughest and cheapest way; and there is but little doubt but that idea fairly carried is a beneficial one. Orchard-houses, however, are now of more significance; many that I have seen are elegant structures of great extent, and some are even heated with hot-water pipes, so that the fruit trees are better protected both when in blossom and when ripening their fruit; and besides that, the wood is more certain to be well matured for successive crops year by year. My object in this paper, however, is not so much to enter into arguments either for or against this somewhat novel mode of cultivating our, what may be called, half-hardy fruits. The fact is patent enough that orchard-houses are now very numerous throughout the country, and time will show whether they are really useful structures. In the meanwhile, as shade is beneficial in hot clear sunny weather, there cannot be a more beautiful and at the same time more useful mode of obtaining that shade than by planting the more hardy kinds of Grape Vines for that purpose, or even some might be grown in the bush style amongst the Peaches, Nectarines, Plums, Pears, and other inhabitants of the glass-covered orchard. The pillars

that support the roof might also be clothed with the ample foliage, the fragrant blossoms, and the rich juicy fruit of the Vine. I might even go further, and say that an orchard-house might easily be converted into a graperly—a consummation that would be desirable in case the other kinds of fruit should from any cause have failed to give satisfaction.

The points of culture to be attended to in order to succeed with the Vine in the orchard-house may be briefly stated to consist of, first, the selection of suitable kinds; second, the right kind of soil; third, planting; fourth, pruning; fifth, training; sixth, watering; and seventh, general management.

VINES SUITABLE FOR THE ORCHARD-HOUSE.—*Black*, Black Hamburg, Black Champion, Ingram's Prince of Wales, Black Prince, Lombard, Black Muscadine, Esperone. *White*, Royal Muscadine, Dutch White Sweetwater, Golden Hamburg, Pitmanston, White Cluster.

SOIL.—The same compost that I have described as suitable for the borders of a viney is equally suitable for the orchard-house. It is indispensable that the borders should be thoroughly drained, especially if the subsoil is of a clayey nature. As the other fruit trees will require their due share of nutriment, the Vines should have a rather richer soil than is desirable for a common Vine-border: hence a good mulching of rotten dung should be spread over the surface round each Vine every autumn to restore the necessary nutriment that the Vines have drawn from the soil.

PLANTING.—Strong, well-rooted Vines should be chosen to plant in the orchard-house. If Vines that have been fruited one year in pots could be procured, they would be excellent for the purpose. The right time to plant them is early in February, before the sap begins to rise. Open a hole large enough to allow the roots to be spread out every way from the stem, then turn the plant out of the pot, and carefully uncoil the roots, and place the stem in the centre of the hole, reserving as much of the ball entire as is consistent with getting the main roots disentangled. Take care not to bury the stem any deeper than it was in the pot. When all this has been satisfactorily done, then if such a thing can be had, cover the roots 2 inches deep with well-decomposed leaf mould. If that cannot be had, then cover them with some of the compost that has been run through a coarse sieve. Press this down gently, and give a good watering with tepid water, which will settle the soil close to the roots, and then root-action will immediately commence.

WATERING.—As the border in the orchard-house is covered with glass, it can never be watered from the clouds: hence it is necessary to supply that indispensable element from the watering-pot. If rightly managed, every drop of rain that falls on the roof will be conveyed by gutters to a large cistern and preserved in it for the use of the orchard-house. It should be given in moderate quantities during the winter months, but when the Vines and other fruit trees are in full leaf it should be given most abundantly. When the trees are in bloom rather less will be necessary, and less also when the fruit and wood are ripening; but the soil should never be dust dry, because when in that state the fine fibrous roots will shrivel up and perish. If a dry air is needful—and that will be so when it is desired to keep Grapes hanging after being ripe any length of time—then to effect this the border may be covered either with large slates or dry sand, or where appearance is no object, with dry coal ashes. During the most growing season—that is, when the Vines are growing freely, and the berries swelling, a good watering once every seven or ten days with liquid manure will be very beneficial; but the moment the fruit begins to change colour, desist from using this enriched water.

PRUNING AND TRAINING.—The mode of pruning depends upon the mode of training: hence it is necessary to consider both operations at one and the same time. If the Vines are used to cover the roof, the spur-system should be adopted—that is, one main stem should be trained up to each rafter, or if there are no rafters, then strong wires 5 ft. or 6 feet apart should be fixed to the roof to train the Vines to. The pruning then will be to cut off the laterals every autumn down to the lowest bud, and shorten in the leading shoot to about 5 feet or 6 feet till the entire length the Vine was to cover is furnished with spurs. After that for several years the spur-pruning will be all that is required.

For the bush Vine the pruning will be on the same principle—that is, forming spurs; but each spur will be, as it were, independent. There will be no leading stem. The bush will stand on one leg, and branches come out regularly on every side

so as to form a bush like a Currant or Gooseberry bush. Every year at the pruning time the young shoots should be cut back to the lowest eye. By this mode a Grape bush will be many years before it is too large for the orchard-house.

Then there is the spiral Vine. This is formed by placing five strong, tall stakes in a circle, the diameter of which may be 2½ feet or 3 feet. To prune the Vine for forming a spiral, let it be cut down as soon as it is planted to three eyes. I use three for fear of accidents. Let them all break, and as soon as possible tie the best shoot to one of the stakes, stop the other two at the third leaf, and as the leading shoot advances tie it to the next stake in a sloping direction upwards, and so continue to secure the shoot to each stake as long as it will grow. Eventually I should expect it will reach to the top of the stakes. Observe, each round should be a foot at least above the last. Keep the laterals well stopped through the summer, and when the wood of the stem appears of a brown colour cut those laterals clean away. Then in the pruning season—that is, about the end of the year, cut the shoot back to half its length, choosing a good prominent bud for starting the following year. After that let the main stem be furnished with spurs, but not too many. I find one every 15 inches is a good average distance; the rest of the buds should be rubbed off just after starting. A Vine trained thus spirally when arrived to some size is very fruitful, and also very handsome when in fruit.

STANDARDS.—This is the last mode of training worth noticing. To form these nothing more is needed than to place a strong stake close to the Vines as soon as they are planted, care having been taken to procure them tall enough for the purpose, cut them to the desired height, and disbud them up to three top-most buds. Then tie them to the stakes, and when the buds are breaking procure as many iron hoops, not flat but round, or if ones could be got and formed into the same shape they would do better; the iron ones must of course be painted. Let one of these hoops be fixed to the top of a stake, and when the three shoots are long enough bring them down by degrees and tie them to the ring or hoop. These at first need not be above 18 inches. The shoots should be trained equidistant from each other. In the autumn these shoots may be pruned in just to the hoop, and other three brought out from the base of each shoot, so that the second year there will be six branches, and that number will be found sufficient to form the head of the standard. In time it will be necessary to have a second hoop of wider dimensions, but that must be the extent, or the standard will occupy too much space.

An avenue of Vine standards would be a pleasant sight, especially if they were all uniform in height and breadth. The bunches would hang down below the shoots, and the effect would be unique.

GENERAL MANAGEMENT.—The management of the Vine in the orchard-house is not dissimilar to that of its management in the greenhouse. All useless summer shoots should be kept under, and such as have fruit stopped at a joint above the bunch; the bunches must be thinned pretty freely when the berries are the size of small Peas. Also, observe never to be too greedy of fruit; it is far better to have an average crop of fair-sized bunches with berries well swelled than to have a great number of small bunches and small berries. The giving freely of air, attention to the destruction of insects, the free use of the syringe after the berries are set, all these are points of culture that the amateur will duly attend to. T. APFLEBY.

PINE-APPLE CULTURE.

I HAVE a span-roofed house for growing Pine Apples divided into three compartments, each 16 feet long by 11 feet 6 inches. Path down the centre, leaving tan-beds (partly heated by hot water) on each side 4 feet 3 inches wide. How many Pines ought to be annually fruited in such a house? The house is well supplied with evaporating-pans. Is there any fear of over-using these at this time of the year?

I have frigi domo covering for frosty weather, to be used at night. Do you advise its general use at night (frost or no frost) to prevent the rapid condensation of vapour on the glass, and to allow the requisite temperature to be kept up with less fire heat? Or would its general use at night (as my gardener believes) draw the plants? I cannot imagine this possible, as no light would thereby be excluded.

My span-roof is erected on the orchard-house system with

light rafters 20 inches apart: the house, therefore, is unusually light. During the late frost (thermometer at 16°) we had no difficulty in keeping up the temperature inside at from 65° to 70° at night. But I have thought of double glazing, but am deterred from the expensive experiment by the fear that green fungus may accumulate between the two inner surfaces of the glass which it would be impossible to remove.

In addition to three moveable lights in the roof of each house, ventilation may be supplied to any one or all the houses by dry drains communicating with the potting-shed and the open air. We find this a very useful method of supplying air in cold weather.

Is the deficiency of flavour in the new Providence Pines grown in this country owing to the want of light in most of the old glass houses, or is it an inferior sort of Pine Apple?—C. S.

[If you allow 24 inches to 30 inches to each plant, and more if the plants are large, you may calculate for yourself how many fruiting plants each space will hold. When Pines are swelling their fruit, 65° at night would be high enough. These will need more atmospheric moisture than those growing or merely showing fruit; but even in those swelling the moisture should not be overdone, as the fruit is apt to be inferior in flavour in consequence, and also to be hollow and rotten at the heart. The others growing will need much less moisture in the air. That must be regulated by the amount of fire heat given. There is not the same need of covering in mild weather as in cold, but there will be little drawing of the plants in consequence, if the temperature inside is low enough. However, in mild, clear, moonlight nights, we would rather keep it off. A little air will prevent so much condensation. If double glazing is so well done as to prevent all air or moisture penetrating to the enclosed space, there would be little danger of the green matter forming; if not, it will be sure to do so: hence in double glazing it is best to have the upper glass, at least, moveable in sashes. There can be no question as to the mode of supplying air.]

The Providence is not a first-rate Pine. It is better in general in this country than in its native home, and is very rich indeed, if not deluged with too much moisture and it is cut before it is over-ripe. The other matters are under consideration. To get at minutiae, at present, journeys would be necessary, and general details have already been given.]

PEACH-TREE PRUNING.

In forming a handsome and prolific Peach tree, although much is to be accomplished by stopping and disbudding—i.e. preventive pruning—still the use of the knife in moderation is necessary. The modes of training to which this tree has been subjected are very various, and many of them very fanciful. We, however, have not now to enter into a description of the vagaries of "Hitt" and "Hayward," or to expatiate upon the far-famed system of the Montreuil gardeners, whose success, although great and indisputable, is probably owing more to their sunshine than their superior skill—for no amount of skill on the part of the pruner can compensate for immature wood, and the injurious effects of late spring frosts. We shall, therefore, confine our observations to the mode of training principally adopted in this country—viz., what is termed fan training.

As the fruit of the Peach is produced upon the last year's wood (fig. 1, in which c c are blossom-buds, with a leaf-bud between them), it is important to adopt such a mode of training as shall insure a constant succession of young wood. This is, perhaps, not accomplished in a more simple and regular manner by any other mode with which we are acquainted; and as our object is the elucidation of principles involving practical results, rather than to investigate hypothetical fancies, we would refer such of our readers as desire to drink deep of this kind of knowledge to the more copious treatises on the subject by various authors, more particularly to the "Encyclopedia of Gardening," by the indefatigable Loudon, where training suitable "to all sorts and conditions" of gardeners may be found.

Let us now proceed to the commencement of the fan-shaped tree, which we will suppose to be what in nursery parlance is called a "maiden" tree—that is, it has made one year's growth from a bud inserted in the stock in the previous year. Fig. 2 represents such a tree, which for the first season is to be headed down to four eyes, so as to produce in the season following four shoots, two on each side. The plant (fig. 3) has now assumed its rudimentary shape, having four branches diverging from the

common centre like the radii of a wheel. In the following season the upper branches must be shortened, so as to produce each three shoots, one in the centre, one on the upper, and one on the lower side; and the two lower branches must be shortened, so as to produce two shoots each. This will give ten principal shoots, which, when regularly trained, will form the

Fig. 2.

Fig. 1.

Fig. 3.

Fig. 4.

*skeleton of the future tree. These must again be shortened, so as to produce subsidiary shoots, upon which the future fruit is to be borne; always taking care to preserve that which springs from the lowest bud, and not in any subsequent pruning to cut such shoots clean out. Persons who are not conversant with

gardening matters generally spoil their future trees, for want of attention to this point. They do not keep them what we call "at home," and in consequence they become naked and unsightly.

In all Peach pruning it is important to know the distinction between leaf and blossom-buds, and to make every cut to a leaf-bud. The blossom-buds are round and prominent, frequently in pairs; and the leaf-buds are pointed and narrow. (See fig. 1, in which *a* are blossom-buds, and *b b* leaf-buds; a leaf-bud is very often placed between two blossom-buds, *c, c, c*.) We have said that the fruit of the Peach is produced upon the shoots of the previous year, which having once borne it, cannot do so again. The grand object of the pruner, therefore, must be to provide an ample and regular supply of them in every part of the tree, and to take care that one part does not deprive another of its allotted nutriment.

When the tree is fairly formed and fruit is expected, great care must be taken to have this succession of young wood; and as the principal arrangement of the young shoots is made during the period of their infancy (and called disbudbing), we will proceed to offer a few remarks upon it, first explaining by fig. 1 the mode in which the succession is kept up. From *A* to *B* represent a piece of two-year-old wood, which has borne fruit in the past year; from *B* to *C* is wood of last year's growth; and the shoot *D* is also of last year. If the gardener were to retain all the shoots which he finds, his tree would be too crowded; for he must not forget the importance of light, to which we have so often adverted. He will, therefore, cut out the new barren wood from *A* to *B*, with its point of young growth *C*, leaving the shoot *D* to replace it for next season; to be itself replaced by a new shoot from the lowest bud at its base. By observing this rule *ad infinitum*, trees may be kept well furnished with bearing wood for many years, whilst by neglecting it the first trees may be spoiled in two years.

When an additional supply of young wood is required, the young shoots must be shortened back to within a few inches of the base. In the case of shoots which have few leaf-buds, and those only at the extremities, if this is not attended to, nakedness must result. It is of consequence in fan training that a certain proportion of wood be annually cut back for future supply. Where wood is not wanted, some of the shoots may be retained at their full length; but the greater proportion may be shortened a little, as the points will often be found unripe.

We now come to the consideration of a portion of preventive pruning, which does, or should do, the greater part of the regulation of the wood of the complete tree in a state of full bearing. We mean disbudbing. It must be apparent that if all the leaf-buds upon the last year's shoots were allowed to grow uncontrolled, a forest of spray would be produced, which would be weak, watery, and unripe, instead of being hard as mahogany, with plump and well-organised buds; and it is equally true that there is a certain quantum of foliage necessary for the elaboration of sap under the influence of light. All superfluous growths, then, instead of adding to, diminish the store of organisable matter for a future year; hence the importance of removing them in their young state, and preventing their undue appropriation of those energies of the tree, for which, in their crowded state, they can reciprocate nothing.

We will suppose the fruit of the Peach just formed, and the young shoot from 1½ inch to 2½ inches in length. This is the period most important in the formation and perpetuation of the supply of young wood. All which are not required for next year's bearing must now be removed, always leaving that one which proceeds from the lowermost bud and the leading one, and thinning the other so as to leave no more than can be exposed to light and air. When a fruit is formed at the base of a shoot which would otherwise be removed as unnecessary, it may be stopped at about 2½ inches or 3 inches, as the leaves assist in elaborating matter for its nourishment. Frequently what are called "adventitious" buds are protruded from the old wood (this occurs most commonly in Royal George Peaches); the careful operator will not fail to regard as a great boon any that are well placed, and to preserve them accordingly.

The great art of pruning consists in so arranging and balancing the parts of a tree that no one attains undue luxuriance, or becomes, on the other hand, too much debilitated from its low position or over-bearing. Constant care is necessary to arrest the undue progress of the stronger wood by timely pinching (stopping), and it is the judicious practice of an excellent gardener to stop the points of all the central shoots about the time

of the maturation of the fruit, leaving the lower branches untouched, and allowing them to continue their growth.

It is usual, in fan training the Peach, to allow the young wood to be produced both on the upper and lower side of the principal branches. Mr. Seymour, an excellent gardener, departed from this rule, training his young wood exclusively on the upper side. We have ourselves also departed from the rule, but on the contrary obtain all our bearing wood from the under or lower side of them; and we venture to recommend this, because in our opinion the tree is balanced better, and produces wood of more moderate growth, the sap always flowing with a vigour proportionate to the vertical direction of the branches.

All who would have good Peach trees must pay great attention to the disbudbing process; this, with timely stopping and occasional curtailment of gross-feeding roots, will nearly supersede the ordinary amputation practice. If the inquiry which we so often hear made—How should I cut my trees?—were changed into "How shall I prevent my trees from requiring so much pruning?" cutting and maiming would be at a discount, and success more frequent both with amateurs and professional men.—H. BAILEY, *Gardener, Nuseham.*

HERBACEOUS PLANTS—BEDDING-OUT— PALMA CHRISTI.

A GENTLEMAN writing in your publication of December 10th (without signature), throws out some insinuations against the present system of bedding-out, which in an editorial note you seem rather to resent, and to accuse the writer of being obstinately prejudiced in favour of his own ideas to the exclusion of all else.

Are not the advocates of the system you defend, at least equally open to the charge you bring against your unknown correspondent?

For some years back I have looked sally on at the destruction, one after another, of the collections of herbaceous plants in gardens. Both in my own neighbourhood and elsewhere they have ceased to be the fashion; and no intrinsic merit will save them from being huddled into some out-of-the-way corner, if not absolutely condemned to the rubbish-heap, in order to make room for their less permanent, though, perhaps, more gaudy successors.

The origin of the popularity of the present plan is evident enough. The Earl of A., or the member for Blankshire, leaves home to attend to his parliamentary duties almost before the earliest spring flowers have made their appearance. The ladies of the family, of course, accompany him, and the gardener is left to his own devices until Midsummer-day is long past and the most attractive of the herbaceous-border plants, as well as almost all the flowering shrubs, have had their day. He, consequently, not unaturally turns his attention to the latter months of the summer, during which only his labours are likely to be appreciated by his employer; and for that season, of course, finds his Geraniums, Verbenas, and Calceolarias most effective.

Were the effects of the unnatural time of year at which the London season is fixed to be confined to the gardens of those who frequent the metropolis in the spring months, I should have less to say against the bedding system, which I admit to have very great beauties, and when confined within proper limits and to suitable places to be one of the greatest improvements in modern gardening; but it is very seldom kept within such bounds, and, like the cuckoo poult in the thrush's nest, it has no sooner established itself than it sets about to expel its neighbours without considering the superiority of their title. My lord's gardener, of course, sets the fashion, and the squire's and the rector's at least must follow. It is of no avail for the gardener, or the man-of-all-work who frequently represents him, to plead want of the necessary appliances and of sufficient space to imitate geometrical parterres at the castle. The former must be found by the expulsion of the long-cherished collection of greenhouse plants from their pots and shelves, and the latter by the consignment of the border plants to the rubbish-heap, and the curtailment of the shrubberies to the extent required; so out must go the tenants of both greenhouse and garden without regard to length of occupancy, or getting anything for the tenant-right we think so much of in this part of the world.

The result is, that it is now rare (and is becoming daily more so) to meet with many of our old and favourite occupants of the mixed border; they have long since disappeared from nurseries,

and are rapidly becoming extinct in private gardens also, except a few not always the most attractive, which earn a precarious existence as attendants in the shape of edgings to their more fashionable successors.

You will say, no doubt, "Pooh! this is a crusty old fellow nursing a gouty foot over the fire this damp winter weather, out of sorts with himself, the world in general, and all innovators in particular." But you are out: I have not yet inhabited this "Valle of Tears" for quite a third of a century, have full use of my legs and arms, and am in many respects as great an innovator as any of my neighbours; but I have an affection, perhaps now a little behind the spirit of the age, for old friends, and should like to see them at least provided with a suitable retirement for their old age, if they must perforce yield their former prominent position to the new comers.

I am far from accusing THE JOURNAL OF HORTICULTURE of encroaching thus abuse of the present system, but I think the remark on your anonymous correspondent's paper savoured a little of a tendency that way. In its proper place, and where means exist for the supply of sufficient material in good condition, I think nothing can be better than a well-arranged geometrical parterre filled with the beauties of more favoured climates, and nothing, certainly, can compare with it as to brilliancy and effect in autumn.

By the way, I see that "D." of Deal, has discovered in Paris, that Ricinus Palma Christi makes a handsome ornamental plant in summer. We have had it in this remote corner of the United Kingdom every summer for the last quarter of a century, and in a fine season it makes a truly magnificent object. In the year 1859 I had a plant of it 10 feet high, with a stem 3 inches through, and leaves many of them 18 inches in diameter, of the very variety "D." speaks of, with the red stems. It is very difficult, however, to procure it true from seed. I have failed in doing so the last two seasons, although I got the seeds from one of the first London houses—labelled Ricinus sanguineus it is true, but the produce had none of the beautiful colouring on the stem, though ornamental enough in other respects. The plant, unfortunately, does not ripen seed in our damp climate.—R. S. D., Co. Down, Ireland.

[We endeavour to hold the balance even. We admire herbageous plants, and wish we could obtain more communications concerning them. We admire well-arranged bedded-out plants also; but we have never said a word expressive of a wish that bedding-out should banish herbageous plant culture. No such wish exists with us; but we do say and have said, that every one has a right to ride a hobby of the colour he likes best.—EDS. J. OF H.]

WHITE-COROLLAED FUCHSIA—PROLIFEROUS PRIMULA.

PERMIT me to add to the list of white-coralled Fuchsias at page 253, No. 39, the name of Madame Cornelissen. This, in my humble opinion, is the best of them all, and I think will satisfy your correspondent.

I mentioned some time since a plant of *Cerise Unique* Geranium, which threw up prolific trusses. I have now in blossom a Primula plant which has no less than four trusses one above another. The topmost has five pipes. Mr. Darwin may think it worthy of note that the second, third, and fourth trusses are all central.—P.

WHAT ABOUT THE SCOTCH PEARS?

Now, then, let us have a little more gossiping about the Scotch Pears that challenged all England for labour, symmetry, and size, and carried off first honours at the Royal Horticultural Society's winter Show. Well done, my friend and namesake, Mr. Anderson, Oxenford! Your unprecedented success amply repays the moral courage exhibited by you in beating English growers on their own ground with no less than twenty-two distinct dishes, "all correctly named." You very modestly say, in a private letter to me, that "you are no authority as a fruit grower, and don't wish to be held up prominently to the gardening world." Do not say so, else you will have the hounds at your heels; for it is hard to be beaten by a first-rate authority upon an equal footing as regards climate, &c.; but ten times more so if your opponent only rates himself as an ordinary

practical mortal, with all the difficulties concurrent with an uncertain climate and a naturally cold subsoil.

When the intelligence first reached us, we were quite as much astonished—agreeably in this instance—as we were upon hearing of the insult by a kindred nation on our flag. We certainly would have been less surprised had the samples in question been grown in some of the alluvial soils contiguous to the seashore, beginning from Berwick all the way up the Frith of Forth as far as Stirling, and back again on the other side, round as far up the Frith of Tay as the ancient city of Perth, and through the Cause of Gowrie; or even the lower parts of Ayrshire and Renfrewshire, all of which can boast of a climate from 5° to 16° milder in a general way than Oxenford; and what adds to the phenomenon, there has scarcely been a dry day from July up to the present date in the lower half, geographically speaking, of Scotland, so that all things considered, Mr. Anderson must know a great deal more as to successful cultivation than he takes credit for, else Berkshire, Hampshire, Surrey, Kent, Middlesex, Hertford, Essex, Cambridge, Suffolk, &c., must have been but indifferently represented as to quantity if not as to quality at Kensington on that occasion.

Oxenford is 450 feet above sea level, and lies on a very retentive cold substratum of clay, so that the roots of the trees require to be lifted every two or three years. Mr. Anderson in reply to one or two queries of ours says, "The aspect from which our Pears were gathered was chiefly from the south, and in one or two cases from the south-west. Our soil, I believe, suits Pears pretty well, being of a heavy nature. The subsoil is a most retentive clay. Certainly in this respect not unlike that almost impervious blue and blackish clay, which forms the substratum of the greater part of Middlesex and a large part of Essex and Hampshire, technically named, I believe, 'London clay'; and it is only by frequent lifting up of the roots that we are enabled to get good fruit, and even with this we require dry warm weather in autumn to bring up the quality." Mr. Anderson is somewhat sceptical of the good effects of root-pruning in its general sense. He says on this point, "No, I keep all I can; the lifting is check enough, and I place them in such a medium as will furnish the proper food, and plenty of it for maturing good fruit." Doubtless this is a very wise method; for in the one case the top roots may remain undisturbed, whereas the bringing of them all up towards the surface induces a more fruit-bearing action, and renders them as much within the control of the cultivator as a first-rate-made Vine-border.

In the greater part of this northern clime fruit trees that blossom in April and May produce a very uncertain crop; and our seasons fluctuate so much that it is getting more uncertain every year. Recourse has to be had to protecting material in order to make certainty secure. Observe what Mr. Anderson's experience relative to this: "I have never failed in getting a crop of Pears from our south wall these thirteen years; but I must tell you that I cover in spring with canvas, as otherwise our labour would be lost. Our crop this season has been equal to the average of years, notwithstanding the untoward season of 1860 for ripening wood. To show the contrast, we had scarcely half a hundredweight of Apples in the place. This has been the general rule occasioned in this part by the biting cold easterly winds that prevailed in May when trees were in blossom. Some seasons I feed largely, but this year they received none; consequently the selection was made from our general crop, and we have been using and still have as fine fruit for table as that which carried the prize."

To the cold wet season is doubtless due the retarding of Flemish Beauty, generally fit for use in September and October. Next in order of earliness are Bourré Diel, Bourré de Capianmont, Colmar d'Arenberg, Louise Bonne de Jersey, King Edward's, Marie Louise, Duchesse d'Angoulême, Doyenne Gris. Next a shade later come Bourré Clairganc, Colmar, Winter Nelis, Napoleon, Crasmane. In the next group come Bourré d'Arenberg, Glou Moreau. Later still come the grand stewing Buchanan's Spring Bourré, Rousse Lench, Easter Bourré, Suzette de Bayay, and Marchal de la Cour. The variety called Poire Neill I know nothing of. This is certainly a very respectable array exhibited as they all were, seemingly in first-rate order, and opens up new prospects for northern competition, besides serves as a first-class certificate to Mr. Anderson's future energy in the same direction. He openly acknowledges that he is proud of his luck, not so much on his own account as for the credit of Scotland, in testing what can be done, and particularly as it was the means of shutting the mouth of our great gun, the

'Doctor' who seemingly has not so much to say about Pears as formerly." So much for the credit of Scotland in general, and Oxenford in particular.—JAMES ANDERSON, *Meadow Bank, Uddingstone.*

VARIEGATION IN PLANT LEAVES.

I HAVE read with much interest the papers which from time to time have appeared in your Journal on the subject of the variegation of plants; and, without pretending to give any opinion on the question whether variegation be disease or not, allow me to throw out a few suggestions in favour of the latter hypothesis.

Your logically-minded readers will perceive that it does not follow that variegation is necessarily disease because disease sometimes produces in the leaves of plants an appearance analogous to variegation. The leaves of a Geranium sometimes exhibit round their edges a yellowish-white band when in a sickly state; but this is very different from the pure white band and fresh green of the Flower of the Day, which is no more like disease than sleep is to death—though these are said to be twin sisters.

I have seen also the leaves of a Camellia show symptoms of variegation when unhealthy, but it is not a logical deduction that variegation is disease. After all, may it not be that we are trying to fathom one of those mysterious operations of Nature which to our finite minds must ever remain unfathomable? Can any one explain how it is that parents of dark complexions and black hair sometimes produce offspring with white hair and pink eyes? or (putting albinos aside) with blue eyes and auburn hair?

Is not disease a step towards death? Take a dozen Attraction Geraniums and a dozen plain-leaved ones, are the former less healthy than the latter—more liable to die, more difficult to propagate or multiply? I think not. Where, then, is the disease? There is no sign of it unless it be in the dwarfish habit, and everybody knows that dwarfish stature may be co-existent with good health. I am no botanist, and take only a common-sense view of the matter; but is it not possible that the soil may have something to do with variegation? We all know the bleaching power of the chlorates of lime—may the presence of this salt in the soil produce variegation? The flowers of the Hydrangea may be changed from pink to blue by the addition of iron to the soil. May not the leaves of plants be differently affected by other salts?—M.

MANAGEMENT OF THE LARCH.

In reply to "Sports" I would beg to observe that the Larch is a foreign tree, a native of the Tyrolese, and other mountains in the south of Europe; and were it not an alpine tree, perhaps it would not grow in Scotland at all.

In a thousand cases we see this valuable timber tree very badly treated. Planted on a flat moor in a poor, shallow, heathy soil, unprepared, with a hard tilly subsoil, impervious alike to water and tree roots, with twice the number of trees there ought to be, all struggling for more field in the soil, and light and air above ground. Larch having a small leaf requires much light; and it certainly gets more of this on the slopes of its native hills, where it is under cleaver and more sunny skies than ours. There the trees rise the one above the other, which gives them more light and air than were they growing on a level plain; and we are told that where those trees grow on the slopes of snow-capped mountains when the summer heat dries up the soil at their roots, the same heat melts the snow and sends down a seasonable supply of moisture to their roots.

From many years' observation I am of opinion that frost is the chief agent and cause of the deterioration of the Larch in this cold climate. In the spring just when the Larches are coming into leaf, they are often seared by frost, the sap stagnated from want of the action of the leaves, and becomes food for the Larch bug. In dry seasons, and unfavourable situations, the trees struggle on until the autumnal rains, when they are set growing, and continue to grow till checked all at once by the first sharp frost. Now with immature alburnum, and bark too full of sap, they are bad subjects to stand a severe winter. In this unfavourable state they are often severely frost-bitten, the vessels of the bark burst, and destroyed. Young trees from ten to twenty years old are more liable than older trees.

The first and second following years the blackish blotches appear, here termed "cancers." After the severe winters of 1838 and 1855 cancers were very numerous, not only in the Larch but other trees—viz., Laburnums, Planes, Apples, Currants; and old Broom and Whins were killed to the ground.

Those who wish to grow this valuable timber tree (and it is valuable and durable whether young or old) must pay more attention to its culture, as regards soil, situation, timely thinning, and no pruning until the lower branches are dead, which might be done with a hard wood stick.

The best Larches in this locality grow in a dale at the foot of a felspar granite mountain (felspar's constituents contain much more nutritive qualities than quartz, &c.), in a depository of the debris of decomposing granite. Ferns, sorts, Grasses, Foxgloves, &c., Birch, Hazel, Sloe, Thorn, and Dog Rose, &c., all go to form, and are indicative of, a pretty rich friable loam. The Larches here are 100 feet in height, and as many years old. Some of them girth 10 feet to 11 feet, 4 feet from the ground. Some Norway Spruces are equally large, but some of them are giving—rotting at the heart, the soil being too dry for Spruce, but a good soil for Beech, Oak, and Spanish Chestnut, and certainly for Larch too. And I believe the "King of the Larches," in Scotland at least, grows in a similar soil, but I do not recollect the rock at Dunkeld, in Perthshire. The said tree was planted in 1735, and in 1852 it was 96½ feet high, 15½ feet in girth, 4 feet up, and contains 412 cubic feet.—LLEX, *Donside.*

HURST HOUSE SEEDLING PINE-APPLE, ALIAS FAIRRIE'S QUEEN.

YOUR Raby Castle correspondent (Mr. Shortt) is pretty correct respecting the origin of the above Pine-Apple; it was, as he states, raised originally at Hurst House, the stock being purchased by A. Fairrie, Esq., of Mossly Hill, Aigburth, for a certain sum. It was then repurchased by Mr. H. Williams, then gardener at Mossly Hill, on the conditions that he was to leave Mr. Fairrie in possession of a stock. If I am wrong in my statements I have no doubt but Mr. Williams will soon set me right. He, with his brother, Mr. B. S. Williams, of the Paradise Nursery, had the honour of sending it out under the name of "Hurst House Seedling;" and, like Mr. Shortt, I do not see the necessity of rechristening after being before the public so many years under its original name.

It appears, from conversation I have had with several first-class gardeners who purchased stock of it, to be somewhat shy at starting into fruit. I am sorry if such is its true character. When I saw the original stock at Aigburth it appeared to be as easy a fruiter as the Queen. Certainly it is a desideratum where room is an object. Flavour I cannot give an opinion of further than Mr. Williams, the then gardener, whose honesty I cannot doubt, said that it was excellent in all respects.—JOHN EDLINGTON, *Cram Castle, Newtown Butler, Ireland.*

NOTES ON MY HERBACEOUS GARDEN.

(Continued from page 217.)

THE four beds under notice in this paper were ovals, about 8 feet over, and were match pairs; consequently, some regard was paid to bringing the occupants of each bed as uniform in height as circumstances would permit. The question of colours was not so predominate a subject then as now.

NOTES ON BED No. 2.

This and No. 3 were planted at one time. No. 2 was planted with *Aquilegia canadensis* (purple Columbine), in October. This, unlike the *Dolphinsium*, succeeds best from seeds, which were sown in April and transplanted in good soil in the reserve garden. An edging of the white *Alyssum*, of a good width, was placed round the bed; and round the inner side of this was a double row of blue Crocus.

Since the penning of these notes there have been several additions to the *Aquilegia*. A *Skinneri* is the most beautiful of these—viz., scarlet and yellow, and is very beautiful.

On reference to my notes of this bed, I find that after the first few days of March are past the *Alyssum* is producing its white and welcome flower-heads in abundance. The sheltered situation of this bed is very favourable for this early spring flower; and should the weather prove fine and open, it will in a

week afterwards present a neat margin of a pure sheet of white flowers. The last days of April have been gay days with this bed. The white edging backed by the double row of blue Crocus has received many gratifying commendations. The Aquilegias, too, are putting forward an occasional flower, and will continue to gain more in number daily.

May is gone, and with it most of the flowers of this bed. I will see to filling it again at once. The Alyssum will be taken back to its old quarters in the reserve garden, planted under a high north fence in a compost which consists chiefly of sifted cinder-ashes. The Crocuses, too, will be brought here, but the Aquilegias will be taken to the rubbish-heap. The bed must then be forked; for the Antirrhinums, which have been grown carefully in pots and plunged for the summer display of this bed, are getting impatient for a move. I will take the first opportunity to bring them here, will saturate the ball of each plant entire previously to planting, and this done and the bed well filled, will muddle the bed over with a layer of fresh-gathered moss from the wood.

I have found this moss one of the best materials for mulching flower-beds, as it has no unsightly appearance, and, as well as obstructing the direct rays of the sun, prevents evaporation from the earth. It need not remain on more than a week.

As yet, June numbers but twenty-three days, and the Antirrhinums are decked with flowers; copious waterings in dry weather, with care not to let any number of seed-vessels accumulate, and they will flower on till September.

BED NO. 3.

This, as stated in No. 2, was filled in October, but not with the same kind of plants. Double Wallflowers were the chosen objects for the spring decoration of this bed from plants struck in the autumn of 1852, wintered in their cutting-pots with a little protection, and finally planted out in the reserve garden in the spring, where they had made fine plants by the time of their removal here. This bed had an edging of the blue Alyssum, backed by a double row of white Crocus. We have already had many April days; Crocuses are gay, but the little blue or purple Alyssum I find is not so proof against cold weather as its neighbour the white.

May day has been and gone this week past, but its occasional warm days have brought the Wallflowers to a high state of perfection; so fragrant are they on a still warm day, that the air for a short distance around them breathes a peculiar faintness.

June is here, and still some handsome spikes of flowers remain on the occupants of the bed; but they must soon be sacrificed, for the Pentstemons, grown expressly to take their place, require to be here, and must be brought at once. I will first well water them, and then plunge them in their pots, will transfer the Wallflowers to the reserve garden, where they will produce by autumn a good batch of cuttings. The little purple Alyssum I will let remain, to see if by such a plan it can be induced to flower stronger next spring. Crocuses, too, can remain to perfect their bulbs. I will continue to nip off the exhausted flower-stalks from the Pentstemons, as by letting them remain they are liable to check the flowering of the rising spikes.

The remaining two orals were planted within a few days of Nos. 2 and 3. No. 1 had plunged in it some dwarf stocky plants of the *Ancuba japonica* grown in pots, and had an edging of Snowdrops; while No. 5 was being planted with the single Wallflowers, and had, as an edging, a stout ring of Winter Aconites.

This might have been termed their winter clothing. It certainly has done much to make the garden look cheerful through the dull months of winter, and, as spring crept on, the Snowdrops and Aconites gave an additional charm; but the sunny days of March are here—all is bustle and haste, so much wants doing and has to be done. I will clear away No. 4 immediately. I have in readiness for this bed a dozen plants of *Dielytra spectabilis*. The bed must be well trenched and manured, as they will be placed here for a permanency.

I have no further notes of this bed in the same year. In the next year I find it was in flower at the beginning of April. At the end of May had grown very strong, and was flowering luxuriantly, and continued to do so with the aid of copious drenchings of manure water at the roots for five consecutive months from the commencement.

BED NO. 5.

The Wallflowers in this bed were allowed to remain and flower; for they cung *Fuchsias*, which have been raised to make

(this a permanent bed also, were too tender to stand against the cold winds of March. The bedding out-season has arrived. Proceed to clear the bed at once; and after it has gone through the same process of trenching and manuring as its neighbour, I will turn out the young plants of *Fuchsia Eppisii* directly. I have great expectations of these two beds when well established, and I am persuaded that the graceful bearing of both will not fail to enlist a whole host of admirers.

Before I close this paper, allow me to say a few words in reply to the humorous remarks attached by you to my last article. I do not deny the charge of trying to wage a war against the present bedding system; but you say you cannot comprehend why I do so. I ask you, is a man expected to be a silent spectator of the ills and hardships his favourites are receiving from the hands of the advocates of the bedding system, and not to raise even his finger in their defence? But, perhaps, you have not seen how they are buffeted about, how they are placed in out-of-the-way places, in soilless nooks and corners, and there expected to thrive and flourish! and because they fail to do this, in such unreasonable places, they are banished and discarded, eradicated and condemned as worthless. If I am expected to bear all this in silence, I will henceforth do so without a murmur; but it will be with an inward gratification, that the day is not far distant when my old garden favourites will be once more occupying prominent places in the gardens of our nobles.—J. C. CLARKE, *Wakefield Place*.

[There is no progress without some enthusiasm, and we readily give a place to the zealous sentences of our determined champion of the Herbaceae. We admire them as much as he does, but we cannot be so exterminating as to wish that no quarter be shown to the bedders.—EDS.]

CLIMBERS FOR GREENHOUSE—PRUNING PLUMBAGO CAPENSIS.

WILL you recommend me a climber for my greenhouse? I want it to run up a twelve-foot wall and then along a fifteen-foot iron tie. The latter is the part I care about, as the wall is tolerably covered. Three similar stations are occupied by a *Tacsonia*, *Cobaea scandens*, and *Mandevilla stuebeliana*.

Also, how am I to treat a *Plumbago capensis* planted against the wall last year, and now covering it up to 7 feet or 8 feet? Must it be cut back?—J. R. W.

[*Bignonia Cheriri*, or *Passiflora racemosa coccinea*.

Merely shorten the top shoots of the *Plumbago* until it fills the space. When done flowering, all the side shoots below may be cut back to a bud or two. The flowers are produced on the young shoots of the summer's growth, which come from well-ripened buds on the shoots of the previous year. When established, you may prune it like a Vine on the spur system.]

NEW AND RARE PLANTS.

STANOPEA BUCCEPHALUS (*Bull-horned Stanopea*).

Nat. Ord., Orchidaceae. *Linna.*, *Gynandrium Monandrium*. This Orchid has also been called *Epidendrum grandiflorum*, and *Anguloa grandiflora*. Perhaps the richest-coloured flowers in the genus, being "a rich tawny orange, with deep blood-coloured spots," and so highly fragrant as to be too powerful for the drawing-room. Native of Ecuador, and in the Andes at an elevation of 6000 feet between Guaracul and Loja. Blooms in August.—(*Botanical Mag.*, t. 5278.)

VACCINIUM IMRAYI (*Dr. Imray's Vaccinium*).

Nat. Ord., Vacciniaceae. *Linna.*, *Oxandria Monogynia*. Native of the Island of Dominica. Handsome evergreen shrub, not more than 3 feet high. Flowers yellowish-green.—(*Ibid.*, t. 5279.)

HIGGINSA REGALIS (*Royal Higginisia*).

Nat. Ord., Rubiaceae. *Linna.*, *Tetrandria Monogynia*. Called also *Campylobotrys regalisa*. "No plant is better worthy of cultivation in the stove," on account of the extraordinary beauty of the leaves. These have a plaited upper surface, which is dark green passing to whitish-green in the plaits, and beneath purplish-crimson.—(*Ibid.*, t. 5280.)

FOBINACEA ANGSTIFOLIA (*Narrow-leaved Echinacea*).

Nat. Ord., Compositae. *Linna.*, *Syngenesia Frustranea*. Native of Texas, Iowa, Illinois, and Wisconsin. Flowers 6 inches across; rays purplish-pink; height 2 feet. May be grown in tufts in the open border.—(*Ibid.*, t. 5281.)

CAMPANEA GRANDIFLORA (LARGE-FLOWERED CAMPANEA).

Nat. Ord., Gesneraceæ. *Lin.*, Didymia Angiosperma. It has also been called *Besleria* and *Drymonia grandiflora*. It is very beautiful, and M. Van Houtte says that it thrives perfectly in a greenhouse, having for its soil a mixture of leaf mould and

loam. The stems are subsucculent, somewhat woody at the base, with opposite, oval, stalked, softly hairy leaves, of moderate size, sometimes unequal at the base, more or less acuminate and crenate-dentate on the margin. The flowers grow from the axils

of the leaves, and the ends of the shoots, on longish peduncles, which are terminated by a few (about three), large, very showy blossoms on long erect pedicels; these flowers are large, nodding, irregularly campanulate, the tubes curved and ventricose beneath, the limb oblique, of five broad-spreading, nearly equal emarginate lobes; they are white, downy on the outside, the face of

the hub elegantly marked with close dotted lines of rosy-purple. "We may hope to see numerous hybrids combining the beauty of this type with that of other Gesneraceæ." Native of New Grenada and Santa Fe de Bogota. Introduced to the continental gardens by M. Linden, in 1847.

THE CONSTRUCTION AND USES OF HYGROMETERS.

VARIOUS have been the instruments which philosophers have invented for ascertaining the hygrometrical state of the atmosphere. Catgut, wood, the beard of the wild oat, &c., were formerly used, but their hygrometrical properties vanished by constant exposure. De Saussure used the human hair, and De Lue a thin piece of transverse grain of whalebone; but where variation in length, volume, or weight is the mode of action, no dependance can be placed upon the instrument. Daniel's

hygrometer, which is a very good one, has many disadvantages—requiring very careful manipulation, and other of the best quality. There is no instrument so good as a pair of good thermometers, the bulb of one being enclosed in thin muslin, to which is attached a piece of lamp-cotton wick communicating with a vessel of rain water; these should be renewed once a-month.

The conversion of liquids into elastic fluids is evaporation, and

this goes on at all temperatures, from the hottest day in summer to the coldest night in winter; and if we only call 30 inches the annual amount evaporated from the surface of the waters of this globe (a quantity in all probability much below the average), water to the amount of 62,000 solid miles is each year changed into clouds, which clouds condense in their turn and form the copious showers which water the plants and supply the springs. When we consider the moist condition of the soil, an additional supply of evaporation must be added to make up the deficiency in this calculation. The process is carried on in the following manner:—The great oceans supply the air with moisture; the heat of the sun causing rapid evaporation, the aqueous particles are carried into the atmosphere in an invisible state until they approach a cold current, when they condense, and are visible as clouds, which float along until a further condensation precipitates them in the condition of rain, snow, or hail; these, when they fall on dry land, hasten along, accumulating rapidly, until the drops of rain form a stream, streamlets accumulate into rivers, and, at last, the drop is conveyed back to its parent, the ocean. The rivers all flow into the sea, carrying large volumes of water, yet the seas are never too full; and why? The oceans give back an equivalent, for evaporation is the cause, the making of rivers, and is constantly going on to keep them flowing. Springs of water owe their supply to the same cause, and are cold or warm according to the temperature of the different underground strata through which they happen to flow. A mountain stream—*i. e.*, one originating on a high hill, is cold, whereas one whose reservoir is deep in the earth is warm; as for instance, the warm springs of Bath, or the still warmer ones of Iceland. Vapour is most plentiful at the equator, becoming gradually less abundant as we near either pole; but in tropical countries it is held in an invisible state, whereas, in colder regions it is condensed into clouds.

The dry and wet bulb thermometer is a modification of Dr. Mason's hygrometer. The latter has a glass fountain for the supply of water, which is easily broken by frost, whilst the common dry and wet ball thermometer is furnished with a zinc

cup, having a lid with a hole in the centre for the cotton conductor to pass through; the cup is situated away from the dry ball, and its surface covered, in order that the evaporation from the water may not influence its readings. The bulb, which is covered by muslin, and moistened by means of the water conveyed by capillary action up the cotton wick, will show a temperature depending upon the following circumstances:—“The air in contact with the wet bulb gives enough of heat to vaporise the water, which being converted into vapour sufficient in quantity to saturate the space which the air occupies, the reduction of temperature will be according to the quantity of heat which has been combined in order to change its state from water to vapour.” The difference indicated by the dry and by the wet bulb thermometer is occasionally (between April and September), 18°, and frequently from 9° to 12°; in other months, seldom more than 9°, and more frequently 4°; and in the depth of winter 1° to 2°. The temperature of the dew-point, which is deduced from the readings of the dry and wet bulb thermometers, is occasionally 30° below the temperature of the dry bulb thermometer, frequently in the summer 20°, and between September and April, 6° to 15°. When the pressure of the air is recorded (by a good barometer), at the same time with the readings of the dry and wet bulb thermometers, a number of useful and interesting particulars may be calculated. As an example, let us take the observations made at the observatory, Highfield House, during the quarter ending June 30th, 1850; the mean pressure by the barometer was 29.726 inches; mean temperature by dry bulb thermometer 52.8°; mean temperature by wet bulb thermometer 49°. From these we learn that the mean temperature of the dew point was 45.5°; the mean weight of vapour in a cubic foot of air was 3.7 grains; the mean additional weight required to saturate a cubic foot of air was one grain; the mean degree of humidity was 0.789 (1.000=complete saturation), the mean whole amount of water in a vertical column of the atmosphere was 4.5 grains; the mean weight of a cubic foot of air was 532 grains; the mean pressure of dry air was (reduced to the sea level), 29.518 inches, and the mean elastic force of vapour (or pressure of water in the atmosphere), was 0.327 inch.

The use of the dry and wet bulb thermometer to the hothouse gardener is twofold; first, as a weather guide; and second, as a means of regulating an artificial climate to such plants as cannot enjoy themselves except under certain peculiar conditions. With respect to a weather guide, take the example given by Mr. Glaisier. The dry bulb thermometer being 70°, and the wet bulb thermometer 55°, before moisture could be precipitated, the temperature must fall 15° (in which case the precipitation would most likely be mist or small rain); or the dew-point must rise 22.5°; or the quantity of aqueous vapour in a cubic foot of air must increase from 3.76 grains to 8 grains (in which case the rain would be heavy); or the temperature of the air must fall at the same time as the dew-point rises, and some conjecture may be formed of the probable duration and kind of precipitation, according as one or the other of these last-mentioned causes prevails. Without a dry and wet bulb thermometer, many valuable plants have been lost, although the precaution is so easily accomplished. All that is necessary is to learn the mean temperature of the air, and the mean degree of humidity of the climate from whence the plants have been brought. Suppose the temperature to be 70°, and the dew point 50.5°: provide a water tank, furnished with a movable cover, so that a greater or less body of surface water may be exposed as circumstances require; heat your stove up to 70°, and give out as much moisture as will bring down the wet bulb to 57°, and you have then produced an atmosphere in which the plants will flourish.—(E. J. LOWE, F.R.A.S. &c., *Gardeners' Magazine of Botany*.)

FERNS FOR BOUQUETS.

Flora would be glad to know what sort of Ferns are the best to grow for the fronds to be used in forming bouquets? *Flora* can grow them either in the open ground or in a greenhouse.

[For a warmish greenhouse *Adiantum formosum* and *Adiantum cuneatum* are among the best for cutting, only the latter shrivels quickly in bouquets, if not protected by a little oiled skin or gutta percha wound tightly round the stem. *Davallia dissecta*, *D. bullata*, and *D. canariensis*, *Pteris argyrea*, and

P. serrulata, are also each exquisitely beautiful and easily grown. The *Adiantums* (Maiden Hair), and *Davallias* (Hare's-foot), are best for bouquets of flowers for the hand; the *Pteris* kinds are more suitable for a vase. If luxuriant growth for cutting is required we strongly advise the top soil being gently shaken off and replaced by cocoa-nut-fibre refuse. The Ferns thrive in this luxuriantly. It should be covered with soil at the top, however, to keep it down.—E. A. M.]

CALYX OF CAMELLIA FALLING.

Will you inform me what can be the cause of the external folds of the cups of *Camellia*-buds falling off? as I have some which look quite brown and loose, and on being touched drop off, which causes the flowers when open to be wide and flabby, and prevents their lasting long. They are carefully watered. Will it also injure them to give them liquid manure once a-week until the buds open?—INQUIRER.

[Either the middle of the ball of the soil has become too dry, or the soil has been saturated by bad drainage, or you have given the plants too high a temperature suddenly. Use clear water.]

WORK FOR THE WEEK.

KITCHEN GARDEN.

HAVE manure wheeled upon vacant ground when the weather is frosty, and all spare ground turned up as soon as possible, so as to expose it to the action of the weather as long as may be. *Cauliflowers*, if the autumn sowing failed it will be necessary to sow in a box, which may be placed in a forcing-house; and when the plants are of a sufficient size they should be pricked out in a frame or a slight hotbed. *Celery*, the trenches should now be dug out to receive the benefit of the frost; in the spring *Cauliflowers* may be planted in them, and dwarf Peas or Lettuce between, which will be off by the time the trenches will be wanted for the *Celery* plants. *Tolatoes*, if young ones are wanted very early some Early frame, Ash-leaf Kidneys, or any other early varieties, may be planted on a slight hotbed; if it is convenient to plant them immediately they may be laid in any warm place until they begin to start. *Radishes*, sow on a slight hotbed. Dung should now be prepared for forcing the various culinary vegetables which are required early—a considerable quantity of leaves may be used with it.

FLOWER GARDEN.

The flower-beds and borders in many gardens would be enriched by giving them a dressing of decomposed leaf mould, and, where it cannot be obtained, charred vegetable refuse, such as the prunings of shrubs, Gooseberries and Currants, edgings of walks, and many other things which turn up in the course of the season may be cheaply made to form an excellent substitute. Endeavour to forward on every occasion of inclement weather the preparation of labels and pegs for the beds, or any other article which you know will be wanted at the busy time of the year. The protection of plants liable to injury from frost must be attended to according to their respective requirements.

FRUIT GARDEN.

It is advisable to examine every week all the choice kinds of fruiting that may be approaching ripeness, or are found not to be keeping well, so that they may be used at the proper time; for the finest Peas become insipid if allowed to get over-ripe before being used, and the same may be said of many varieties of Apples. Any of the choice kinds of Peas that do not appear to ripen properly in the fruit-room will be improved by being removed to a warm dry room for a few days. Keep the fruit as cool and dry as possible. If frost is excluded it can hardly be too cool to preserve the fruit plump and sound as long as possible.

STOVE.

Keep the atmosphere rather moist, especially if the weather is bright, and remove such plants as are inclined to start into growth to the warmest part of the house. Above all things look out sharply for the scale, mealy bug, and thrips, and wage an incessant war against them at all points. Some plants, such as *Stephanotis*, *Allanandas*, *Mancinellas*, *Dipladenias*, &c., may be pruned, trained, and started—if by a gentle heat all the better; but those plants for late blooming to be kept back for the present. *Luculia gratissima* when done blooming to have the

side branches shortened in a little, and to be placed in heat to produce cuttings for propagation.

GREENHOUSE AND CONSERVATORY.

The weather of late has been so favourable for plants that many of them are growing rather too freely. As this young growth is tender, abundance of air must be given, and great precaution taken to guard against frost, which, like a thief in the night, steals in, and would do an irreparable injury to the young wood in its present state. While at the same time that you guard against frost, it is also advisable to avoid overheating the houses by giving all the air possible at favourable opportunities. Water to be given cautiously, and in the morning; but care to be taken not to allow any plant to suffer for want of it. *Pelargoniums* intended for blooming in May to be shifted into their blooming-pots. Late-blooming plants to be stopped preparatory to potting them off about the end of February. The young stock to be encouraged to get them strong and healthy. *Cinerarias* and herbaceous *Calceolarias* grow best in a warm, moist, airy pit. All such plants as require it to be shifted into light rich soil. Fumigate slightly every ten days or a fortnight; but be very careful not to injure the leaves; water when necessary, but not over the foliage. Take care that the *Camellias* do not suffer for the want of water now they are blooming. Prune, train, and clean the climbers on the rafters, &c.

FORCING-PIT.

This structure will now be kept in full activity to supply the various calls for plants in bloom, which at this season of the year are generally in demand in most places. Care to be taken before plants are removed to sitting-rooms to gradually harden them off for a day or two either by placing them in a greenhouse or any other intermediate-house. Maintain a fresh, growing, moist temperature of from 60° to 65°, or 70° with sun heat. Syringe early on sunny days, and keep a moist atmosphere, unless the weather is very dull.

PITS AND FRAMES.

Plants of a succulent nature will require much attention during damp foggy weather. *Geraniums*, *Verbenas*, and *Calceolarias* are very liable to become damp and mouldy. Remove all mouldy leaves as soon as they are seen, or they will be certain to infect others, and then spread over the whole stock. It is sometimes advisable, when plants are affected with damp and no means at command to correct it, to move them to other quarters, where a drier temperature is kept. Avoid watering here as much as possible; it is better to let the plants flag a little than to have them saturated at the root. To keep plants in first-rate condition the requisites are a limited supply of water, abundance of light, free circulation of air, and a dry atmosphere. If a sharp frost should set in, and plants have been excluded from the light and air even for a few days, they must not be too suddenly exposed, especially to cold easterly or northerly winds, but should be gradually inured to free exposure.

W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

MUCH the same as last week, with the exception of putting more *Sau-kale* and *Rhubarb* in the heat of the Mushroom-house, earthing a bed in the latter, and packing some tree leaves round the frame of the *Asparagus*-bed, which though put in late, gave us a nice dish on Christmas-day. The *Sau-kale* and *Rhubarb* first put in heat have produced well. *Cauliflower* under protection is excellent, and *Snow's Broccoli* is beginning to heart in the open ground. Will place some litter beside it ready to throw over it in an emergency. Made up a bed of leaves for a twilight box, on which to place earth and sow Early Horn Carrots, with a sprinkling of early frame *Radishes*, which will come in to succeed the *Radish*-box. *Radishes* are still good out of doors, having received a little protection in frost. The bed will produce in a fortnight. Endive covered over with a little stubble is now in fine order, and along with a little Lettuce, Beetroot, and *Celery*, makes a nice Salad.

FRUIT TREES, &c.

Much the same as previous weeks. Placed more *Strawberries* in *Vine*-pits, and also a row on the high shelf of the Peach-house, where they will be free from frost, and come on slowly; the house now being crammed with bedding plants, which must be moved before we begin forcing. Damped the *Vines* in pits, in

warm days, to soften the buds. Laying them close to the ground keeps a moist vapour about them. I do not think that direct light is of much consequence before the buds swell; as soon as they approach bursting-point light and air are essential.

FLOWER DEPARTMENT.

Cleared the most of *Chrysanthemums* from flower-house, and replaced with other things in bloom. Picked off all decaying leaves and fading flowers. Gave plenty of water to *Cinerarias* just coming into bloom. As the flower-house is kept at a low temperature, *Primulas*, *Cinerarias*, *Daphnes*, *Cytisus*, and *Camellias*, are the chief things in bloom. To have a house gay at this season the temperature should average 50°, whilst ours will scarcely average 40°. Bulbs and other forced flowers should be gradually hardened before going into a house ranging even from 45° to 50°. In such open weather, *Violets*, and all sorts of bedding plants should receive all the air possible, and have every decayed leaf and mouldy part taken off close to the fresh stem. If the *Violets* are in a frame it is a good thing to wash the boards inside with sulphur and soft soap. If in a pit do the walls the same. If a little mildew appears on a leaf it is best to nip it off, but if numbers are affected, it will be best to dust the leaves with fine sulphur by means of a fine hair brush. The sulphuring of the walls and boards will be a good preventive.

PLANT-STOVES.

Such plants as *Ixoras*, even if plunged in a hotbed, will be all the better if placed close to the glass, that the points of the shoots may be well hardened to assist in setting the flower-buds. All the light possible in such houses will now be advisable; and therefore such plants as *Ipomaeas*, and *Passion-Flowers* as *quadrangularis*, should be pruned pretty close back to the wood of last year in established plants, leaving a good bud or two as in *Vine* spur-pruning, as from these buds the flowering-shoots of the following summer will come. Old established plants of *Allamandas*, *Stephanotis*, &c., may be pruned much in the same way; but younger plants with fine ripened shoots, but not nearly thick enough to cover their trellises, may have these shoots thinned fully three parts of their length round a trellis—and if these shoots are well ripened, the bending will cause every bud to break and produce its flowering-shoot. The plants should be dry rather than moist before pruning. A few days afterwards the soil may be watered or even top-dressed, and that may be all that is desirable; but if fresh potting is resolved upon, it had better be done after the buds are breaking. The turfy loam and heath soil used should be aired and warmed, that the roots may receive no check by coming in contact with cold soil. In dull wet days out down some large plants of *Adiantums*, as *cuneatum*, &c., and top-dressed the pots, in order that the fronds might be all fresh and green in spring and summer. Potted younger ones, fresh-dressed *Orchids*, and gave a little water to those sufficiently rested. This dull season is not the best for such potting; but a temporary potting-board may be fixed in a house, soil heated and all made comfortable, and many things done now that would stand a poor chance of being attended to in spring, when we could use every pair of hands if increased threefold, and find no fault with more.

PLEASURE GROUNDS.

For cold pits see last week. The day before Christmas-eve was charming, telling of frost at night. Christmas-day equally delightful, enough to fill every heart with gratitude—and with rejoicing, too, but for the heavy bereavement the Queen and Royal Family, and the nation at large, have sustained in the removal of a Prince whose name was never mentioned prominently but in connection with what is noble and elevating, being equally at home directing the councils of the learned men of the age, and in devising model cottages, and inculcating thrift, industry, intelligence, and practical piety for promoting the happiness of the labouring population. Would that many, besides stalwart sons and blooming daughters, would deem it a sacred duty to imitate his example. These five days enabled us to clear the pleasure grounds of leaves and all falling flowers, to sweep and roll the grass and walks, to render them somewhat in accordance with such a glorious Christmas-day. The very brightness of the day would lead us to hope that it might be a good omen, that the dark eld gathering between us and brothers across the water might be thoroughly dissipated, and that at home many a sad lonely heart would be gladdened by the proofs of kind and generous sympathy.—R. F.

TO CORRESPONDENTS.

* * * We request that no one will write privately to the department writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the "Journal of Horticulture, &c."* 162, Fleet Street, London, E.C.

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

We cannot reply privately to any communication unless under very special circumstances.

VINE'S GREENHOUSE (Robin Hood).—We think for a greenhouse 16 feet long four Vines would suit best, one 2 feet from each end, and then the four would be 4 feet from each other. These might be two Black Hamburgs and two Royal Muscadines. Or, if you wished the Grapes to hang long, one Hamburg and one Lady Downes' or St. Peter's, and one Muscadine, and one Kaiser de Calabrese. The time of planting may be any when it suits best. It may be done now if you protect the roots from cold and wet. They will be growing slowly all the winter, if the soil is moderately warm.

WALTONIAN CASE (W. E. C.).—We see nothing wrong in the idea of your Waltonian Case, though if sizes and means of management had been given, we might have judged better. If you cannot make your case cheaper by far than the true Waltonian, you might as well have one at once. We would have some inches of sand over the boiler before setting the pots on it; and we should prefer one of Miss Maling's In-door Plant Cases. There has been more flower gardening in the Journal than in any other work of the day; but if you require more about florists' flowers we recommend you to order "The Florist and Pomologist."

OLD APPLE AND PEAR TREES SEVERELY PRUNED (A Subscriber).—In order to encourage the lower new formed shoots, you must not let the top have too much lead again. These new shoots must be thin enough to let sun and air play upon them. We would now merely shorten the points a little. If you had thinned them out and nipped out the points in June, flower-buds might have been formed on them now near the base. These most likely will be formed next summer. One next summer can be chosen for leader, the rest stopped to 3 inches or 4 inches, and the leader stopped to 6 or 8 or 15 inches. This will give you nice young wood supplied with fruit-buds.

CLIMBERS FOR HOUSE FRONT (F. Fane).—We have repeatedly stated we could not say what kinds of plants to recommend for planting where the country or part of it is not told us. Just consider if you were living at Torquay, or at Cromarty, how very different the kinds of plants for your soil must needs be. Anywhere, however, a border 9 inches wide will do for no kinds of climbers whatever. The pavement might not be so injurious as it would seem if the ground under it had been trenched, and the plants had a fair start before the pavement was laid down.

SELAGINELLA DAMPING OFF (Subscriber).—From the mere fragments sent dried up in blotting-paper, instead of being kept in oil-skin, in which they would have come fresh to hand, we are only enabled to point the plant is some very small kind of *Lycopodium*, allied to *apodum* if not that kind. The damping-off is explained by the place being 10° or 20° too low in temperature for it; or else it is too much confined for want of air. All these *Lycopods*, and the tree-like *Lycopods*, called also *Selaginellas*, will live and thrive amazingly in a dripping-wet atmosphere if the temperature is sufficiently high for them: thus one of them and most of them should now, however, be in a dryish atmosphere of from 50° to 60°; if the delicate ones are in a lower temperature the least moisture will damp them.

BROOMFAN STOCKS (Xiphophora).—If they were ours we should throw away the ill-used stocks, they will never do you or your seedsmen any credit. The next best thing would be to plunge the pots close to the south wall of your house, and have a board ready to put over them to keep off the rain and much of the frost, and to plant them out at the end of March.

LILIPUTIAN CACTI, &c. (W. M.).—There is no work, that we are aware of, upon the culture and propagation of the Liliputian Cacti; nor do we know who raises them for the retailers. We do not know any one who has grown Maclean's Advancer Pea. The common Advancer Pea is a wrinkled blue-seeded variety, very good, and ranks among the second earlies. The Walton's Plant Case is described and figured in No. 339 of THE COTTAGE GARDENER. The papers we are now publishing will teach how to manage plants in such "In-door Cases."

TOMATOES FOR PRESERVING (E. Pugh).—The best for preserving we think is the Cherry-shaped (*Lycopersicon cerasiforme*); but you can have varieties of the common Tomato of various forms and colours. They are red, yellow, and white-fleshed; Melon-shaped, Pear-shaped, &c. If you write to any large seedsmen in London, telling him what you require he would supply you.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

THE POULTRY WORLD IN 1861.

We believe that most men are lazy, and that all men in some things or others are procrastinators. We are. Even in our trifling case there are times when our work seems to accumulate, and as one child said to the other, "The more you call the more I won't come," so the heavier our load the less we seem disposed

to pluck up courage, and to lighten it. No one ever yet intended to commit an extravagance that he did not justify it on the score of economy; and we never defer work without being able to prove, at least to our own satisfaction, that somehow or other benefit will result from the delay. All these things are deceit, and the labour is the same; there is the same expenditure of labour, but it is compressed into a shorter period of time. Many who read this will understand us when we say *the safety valve is weighted*.

Did you ever notice the real difference between men going to the same market and driving themselves? One lites past at the utmost pace of a fast horse, still urging him. His face is flushed, his horse reeks, but when he reaches the Crown and refers to his watch he will be able to say he has accomplished the distance in a very short time, and had on getting there more than half an hour to spare. His neighbour will drive steadily, will start at the same time, and arrive five minutes before market opens. He will have spared his own resources, and those of his horse, while accomplishing all that is necessary.

The connection between time and our present subject has somewhat forced these reflections upon us. This Number appears on the last day of the year, and it will be in few of our subscribers' hands till 1861 has become a matter of history, and a thing of the past, while 1862 has entered into being, untried it is true, but bursting with hope. It is an annual duty to exchange good wishes, and mutual expressions of respect with all our friends, and our task is made easy by the fact that we believe we have none but friends among all those with whom our vocation brings us in contact. We can heartily say we wish for no others, and that we never pen a line or utter a word we would not willingly recall, if we thought it would pain any to whom it was addressed, or into whose hands it fell.

We cannot, especially at the present time, refrain from saying our first feeling is one of gratitude that we are again permitted to begin another year. We "look askew" at those who say at forty they feel as young as they did at thirty. It is only when they feel the approaches of age that they say so. It is some years since we addressed many of our present readers, and while we admit we are older, and know it, we are glad and thankful to say that to the support of our friends and subscribers we are indebted for being able to record 1861 among prosperous years. Such are lighter to bear than troublous ones.

Viewing Poultry in its relation to exhibitions we have to record an increase in its number of shows, a great stir in towns where they were formerly held, but have been discontinued; and the fulfilment of our predictions that the large shows would increase. Everything speaks not only of the continuance but the progress of the movement. There has been an immense stride in Poultry as it applies to food, and men who care nothing for it as a pursuit, are turning their thoughts to it as an adjunct in feeding people. The great want is statistics; we are behind all our continental neighbours in this matter, and it will be only when people can see on irrefragable evidence how much Poultry does, that they will begin to believe how much it can do. The prizes have again been scattered abroad as during the last two or three years. The love of the pursuit is like the dragon's teeth, and hence new names spring up on the prize list. For one that disappears twenty come into notice. It has been said nothing remains stationary, and we believe it. Different classes vary in the estimation of the public, and are now higher, now lower. They would seem to depend on the public for their excellence. They increase in perfection and good quality, just as they are at the top of the public scale or lower. Certain classes seem to depend also on certain men whose countenance would appear to be necessary for the well-being of a breed.

Dorkings have throughout been excellent, not only in size but in health, feathers, and condition. We cannot mark much increase in weight, but it is impossible to go on continually adding to bulk. That which has been accomplished is no trifle, and it has not cost one point of symmetry. Spanish have barely held their own in quality, but their entries have been satisfactory. Cochins-Chinas, in every class but White, have greatly advanced. The Buffs are as good, and the Grouse are better than we ever saw them at any time. Brahma Pootras progress steadily, the world is becoming convinced of their merits, and they now demand a class everywhere. The Hamburgs prosper. The Golden-pencilled and spangled are perfect; the Silver-spangled very good; while the Silver-pencilled have room for improvement. However numerous they might be, Polands could not improve in quality; but their classes are not self-supporting for

lack of entries. We can only say of the Game that we can suggest no improvement.

Bantams may boast of their progress. In number and quality they are shows in themselves. The Golden are excellent; the Silver very much improved; the Black, White, and Game nearly perfect.

Ducks of every breed, Geese, and Turkeys maintain their weights. Rouens are faultless in colour, and the Buenos Aryeans have moved from Brobdingnag to Liliput.

The principal novelty in the various class has been the regular exhibition of Crève Cœur. Should it continue, they may ask for a class. It is worth suggesting to those who have the management of these things, that a class does not necessitate three or even two prizes; one will test the merits and capabilities of a breed.

Our report is "couleur de rose. We have sailed in safety, and things have gone smoothly with us. We offer our best thanks to subscribers, contributors, and all friends, to whom we feel we owe, that we can make this gratifying avowal. May it be the same with them all. It is especially matter of sincere pleasure to us that we can fill our columns, without encouraging discussion in order to supply our readers with highly-spiced personal ragouits. We are proud to avow, that in this respect we are for peace above all.

Grateful for the past, we hope for the future. We would that every one should share in light and cheerful anticipations, and therefore wish to all whom this sheet shall reach

"A HAPPY AND PROSPEROUS NEW YEAR."

FEATHERS OF SILVER-SPANGLED HAMBURGH HEN CHANGED IN THEIR MARKINGS.

I HAVE a capital Silver-spangled Hamburgh hen. She began to lay this day (December 23rd) twelvemonth, and between that time and the middle of October produced 240 eggs. She then moulted. I now see that her tail and wings (or flights rather) are perfectly white; the breast is decidedly marked, but the spots too small; the body cloudy or mottled with very small spots. Now, as her eggs have produced some exceedingly good chickens, and I have obtained a prize cockerel on purpose to get another strain, considering her imperfect markings, would it be worth while to risk chickens from her eggs, or safer to raise them, for the ensuing season, from her pullets, which have just begun to lay?—P.L.L.A.R.I.C.S.

[As you say the hen in question has bred you very good chickens, and you have now bought a prize cock to cross with, we recommend you to put him (being a chicken) to the hen. It is common to many, we may say to most breeds, to fade in colour and to increase in whiteness at each succeeding moult after they become aged. You may give up the barley, potatoes, and wheat in your poultry diet if you will give ground oats and the scraps from the table.]

FEEDING POULTRY.

At this time of the year, and long before this, when the days begin to get short, I feed but twice a day—at nine o'clock in the morning, and two o'clock in the day. At morning they have as much barley as they like to pick up, and at mid-day they have a mixture of boiled potatoes and the scraps from the house, and barley, pea, or bean meal, whichever may be the cheapest or most come-at-able, sometimes ground oats, and when potatoes are getting short in the spring, I add brewer's grains.

Now, all or any of this sort of food does first-rate for store fowls, and I never saw any marked difference, have which sort they may, and the quantity of meal to be used is just as much as will keep the fowls from scouring. Keep an eye to that, and that is the surest guide, and if the house scraps should contain much bread, less meal will do. When the days begin to get light at six in the morning, then I feed at eight in the morning, one in the day, and again at roosting time; giving barley morning and evening, and the hotchpotch, as I call it, at mid-day. This meal I let them eat till they cannot get one bit more down, and I ascertain exactly the quantity of barley they will pick up at that time of the year. Then I have something to measure that quantity; then if I cannot stop to watch them eating I can strew it about and leave them to it, and so they go on till the days

begin to get longer, they got up earlier, and they get more food in the fields. Then the first mornning I see they do not pick their barley up quite clean I at once shorten their allowance, both morning and evening, and they come without calling to every meal, as true to time as I do myself; and although in the very long days their evening meal is, as it were, only the name of the thing, as they scarcely care to pick up a dozen corns a-piece, they will not go to bed happy till they have had it.

I should have stated that I keep curtailing their barley as I see it necessary, but more so in the evening than the morning. I feed extra at moulting time. Their walk affords all other requisites, and by this treatment my fowls are always in excellent health and plumage, and in first-rate laying condition, and always fit to pick up of the walk in good, sound, flashy condition for table. I have a good warm shed for them to roost and lay in, but the greater part of them roost out in a tree close by, and they that are in-doors can go out as early as they please, and they that roost out in all weathers are equal in all respects to those that roost in-doors.

I know plenty of people that have good fowl-houses lock their fowls up in the warm every night, and feed pretty regularly, and have good runs in the bargain, and give their fowls three times the corn that I give mine, and these do not lay in comparison with mine, or do so well in any way, and they wonder how it is; and it is simply this—they are a people that call themselves poultry fanciers that have sprung up within a few years, and some only months as it were, they talk over their management to each other when they meet, and every one thinks his or her plan the best. They buy a poultry-book, and as they do not think to make observations about the habit of the fowl or the situation they are in, many go directly opposite to what the book states. Picture these fanciers' fowls being let out of their house at eight o'clock on a summer's morning, and mine that had hopped out of a tree at four, and come home to breakfast at eight!—WORCESTER.

ROYAL DUBLIN SOCIETY'S POULTRY SHOW

DECEMBER 17TH AND 18TH.

THE show of poultry was very good, the several varieties being well represented in numbers as well as perfection in the specimens. The mature *Dorkings* numbered thirteen lots, and all fit creditably to compete in any show. The first prize was taken by a very fine lot recently brought from England, and we learned competed successfully at the late Birmingham Show. It is to be regretted that the pens are so inconveniently made—the opening being at the back—that it is almost impossible to give a critical judgment, as, where competition is so close, weight must decide the point; many birds looking very large, which, when put into the scale, do not answer the expectation. The *Dorkings* under a year mustered nineteen lots, more interesting than the adults, as showing the result of the breeders' care bestowed upon them, and, as might be expected, the contest was a close one. We could not, however, agree in the award of first prize to lot 22, the Countess of Beative, the birds being too small and the pullets not accurately matched. The second birds reared by Mr. Williams being much superior. Mrs. Farrell's highly commended birds were also very fine. The *Spanish* classes, both old and young, did not show to such perfection as the other breeds, the season being a late one for moulting, so that the birds had not recovered, as was shown in the general want of brilliancy of the combs and wattles, the delicate whiteness of the face, and fullness of tail. Making allowance for this, the show was a good one. The *Cochin-China* class had not many representatives, but the birds were good. The *Gans* class had but few champions to support the cause, and one or two lots, we believe, were disqualified, although separately good birds, because the legs were of different colours.

There was a particularly fine array of the crested breeds, which attracted much attention, both from the size of the crests and the beautiful markings of the birds. The *White-crested Black* birds were very fine, and reflected great credit on the successful exhibitor, Miss Drevlar, who took all the prizes. The class for any other distinct breed contained some beautiful birds of the *Silver* and *Gold-mooned Pheasants*, and divided the prizes between them. These breeds, the pride of Lancashire and Yorkshire, are not sufficiently appreciated in Ireland, as well for their beauty as productiveness. The *Turkeys* were very fine, particularly a pen of Cambridgeshire birds belonging to Mr. Joseph

Tuite, as well as a lot of ten young cocks (American), all of which, we believe, were soon claimed. The double-breasted pied Norfolk Turkeys shown by Mr. D. Campion, Mount Vernon, were also particularly fine. They took our attention, from their elegant appearance, their compactness, and freedom from offal; their flesh is also beautifully white, and they are a very domestic description of bird.

The *Geese* had immense birds to represent the class, among them a pair of Canada Geese, which were greatly admired, and, no doubt, can be easily domesticated, and as they weigh as much as 20 lbs., deserve attention.

The *Rouen Ducks* were all very superior, and as they competed with Aylesbury, showed their superiority by taking all the prizes and commendations. Considerable discussion took place in the awards in this class, as the birds were not weighed, and much difference of opinion existed as to minute points in competition—viz., the marking of the bills, &c.; but we believe the morning was so dark that any slight mistakes, owing to such a cause, should be overlooked where the judgment was generally so good.

DORKING.—First, R. W. Boyle, Rosemount, Dundrum. Second, Countess of Beative, the Lodge, Virginia, county Cavan; R. P. Williams, Hollybrook, Clontarf; Mrs. Laxton, 4, Banna View. *Chickens*.—First, Countess of Beative. Second, R. P. Williams, Clontarf. Highly Commended, Mrs. Farrell, Moyalta. Commended, R. P. Williams, Clontarf.

SPANISH.—Prize, R. P. Williams. *Chickens*.—First, E. J. Smith, jun., 31, Hatfield Square. Second, R. P. Williams. Commended, Miss E. de Courcy Drevlar, Blackrock; J. F. Rest, Roebuck House, Dublin.

COCHIN-CHINA.—First, R. P. Williams. Second, Countess of Beative. *Chickens*.—First, Countess of Beative. Second, R. W. Boyle, Rosemount, Dundrum.

GANS.—First, R. W. Colgan, Blackrock. (Second withheld.) *Chickens*.

—Prize, W. Colgan, Blackrock.

HAMBURGH (Spangled).—First, R. P. Williams. Second, R. W. Boyle, Dundrum. Highly Commended, R. P. Williams. *Chickens*.—First, R. P. Williams. (Second withheld.)

WHITE-CRESTED BLACK FOWL.—First and Second, Miss E. de Courcy Drevlar, Blackrock. *Chickens*.—First and Second, Miss E. de Courcy Drevlar.

ANY OTHER DISTINCT BREED.—First, J. Lafarelle, the Grange, Stillorgan. Second, R. P. Williams. Highly Commended, J. Lafarelle; R. P. Williams.

CHICKENS (SIX, of any breed).—First, R. P. Williams. Second, Mrs. M. Delaney, Castleknock.

CHICKENS (of any breed).—First, R. P. Williams, Hollybrook. (Second withheld.)

TURKEYS.—Second, J. Lentaing. (First withheld.)

TURKEYS (Tallazart).—First and Second, J. Tuite, Mullingar. Second, J. Haydon, 30, North Anne Street.

DUCKS.—First, R. W. Boyle, Dundrum. Second, J. Tuite, Mullingar. *Prize*.—First, R. W. Boyle. Second, H. M. Barton, 4, Harcourt Terrace. Highly Commended, R. P. Williams, Clontarf; R. W. Boyle, Dundrum. Commended, R. P. Williams.

LOT OF TEN DUCKS.—First, R. P. Williams, Clontarf. Second, J. Hyland, 30, North Anne Street. Highly Commended, Mrs. H. Rathmises. —(*Irish Farmer's Gazette*.)

HALIFAX FANCY PIGEON ASSOCIATION.

ON the 20th and 21st, the fourth Show of the Halifax Fancy Pigeon Association was held at the Mechanics' Hall, and both in the number and quality of the birds exhibited was decidedly in advance of that of any previous year. There was an encouraging increase in the number of local exhibitors, and these were Messrs. W. Smith, S. Shaw (Stainland), W. Kelsey, J. Sunderland, jun., E. Drake, J. Bairstow, J. Wadsworth, A. Graydon, G. Hebblethwaite, J. Firth, E. Parry, and S. Thompson. That this Show is regarded with favour elsewhere we have satisfactory proof in the fact that exhibitors attended from the following places:—Forest Hill, Staleybridge, Glossop, Bradford, Newcastle-on-Tyne, Birmingham, Whitehaven, Nottingham, Sheffield, Burnley, Huddersfield, London, Manchester, Liverpool, Gateshead, Lanark, Beverley, Rochdale, Newark, Axminster, Dundee, and Glasgow. There were 413 pens, and specimens of some rare breeds exhibited.

In *Pouters*, Mr. Wm. Smith was highly successful, carrying off the first prizes in Yellow hens, and Dun or Mealy cocks, and the second prizes in three other classes, while he was highly commended in a fourth. He was also the winner of a silver medal, value £2, given by Mr. George Ure, Dundee, for the best pair of *Pouter* cocks or hens of any colour, bred in 1861. In Mr. Peter Eden, of Salford, however, he found a formidable competitor, who carried off the first prize in six different classes, and second prizes in three other classes, while in others he was highly commended. Mr. Geo. Ure, of Dundee, carried off first prizes in four classes, the second prizes in two classes, while in another he was highly commended. The collection was in every respect a magnificent one and excited much attention. A Mealy hen

belonging to Mr. Ridpath, of Manchester, was much admired for its length of body and admirable shape.

In *Carriers*, the most remarkable show was that of Dun cocks, there being seven entries, five of which were noticed, Mr. Thos. Colley, of Sheffield, taking the first prize, and Mr. John Bairstow, of Halifax, the second. In the several classes of Carriers, Mr. Bairstow carried off three first prizes, five second prizes, and in eight cases he was highly commended. Mr. Peter Eden, however, carried off the silver medal, value £2, given by Mr. Matthew Stuart, of Glasgow, for the best pair of Carriers, Dun or Black cocks, and bred in 1861. In this class, the competition was exceedingly keen.

In *Almond Tumblers*, Mr. Eden also carried off the silver medal, value £3, given by Lord Binning, for the best pair; Mr. Matthew Stuart, of Glasgow, winning the silver medal, value £2, given by Mr. James Hnie, of Glasgow, for the second best pair. Mr. Samuel Shaw, of Stainland, carried off four second prizes.

In *Kites* or *Self-colours* there were two admirable hens, both shown by Mr. George Fawdon, of Gateshead, and they were much noticed. The show of Common Tumblers was not very numerous, but they were all of an excellent quality.

The *Jacobins* comprised some of the best birds ever exhibited, Mr. Shaw, of Stainland, carrying off the first prize with Reds.

The *Turkies* were an interesting class; and Mr. Shaw won the silver cup, value £5, given by Mr. W. Wicking, of London, for the best three pairs, subject to his birds being sold for £5 if claimed. The pairs were Black, Blue, and Red, and they were of such an admirable quality that there were several claimants for them.

The Show in other breeds possessed no features calling for special mention save the *Trumpeters*, except that the first prize was awarded to Mr. Shaw's Black Mottles, which have figured conspicuously at all the exhibitions in the kingdom, and have won a little fortune in prizes. These are also the same birds from which Mr. Wolstenholme painted his picture of "The Trumpeter."

The *Dragons* were an unusually large collection, and in the class for "variety" there were some specimens of rare excellence—in fact, such a class as has seldom been brought together. Amongst the most noticeable of these were a pair of "Wonga-Wongas," imported from Australia, and a pair of Laced Fantails. The Show is, without doubt, the most successful of any that has yet been held in England, and its success is owing mainly to the unanimous working of the Committee, each member having laboured heartily to give to the Show the utmost *éclat* possible.

The following is the list of prizes awarded:—

POULTRY.—*Blue Cocks*.—First, P. Eden, Salford. Second, W. Smith, Halifax. Highly Commended, S. Shaw, Stainland. *Blue Hens*.—First, P. Eden, Salford. Second, W. Smith, Halifax. Commended, W. Taylor, Sheffield. *Black Cocks*.—First, G. Ure, Dundee. Second, W. Smith, Halifax. *Black Hens*.—First, G. Ure, Dundee. Second, J. Hnie, Glasgow. Highly Commended, I. H. Frame, Lanark. *Red Cocks*.—First and Second, G. Ure, Dundee. Highly Commended, P. Eden, Salford; W. Smith, Halifax. *Red Hens*.—First, G. Ure, Dundee. Second, J. Sunderlind, junr., Halifax. Highly Commended, J. Smith, Sheffield. *Yellow Cocks*.—First and second, P. Eden, Salford. *Yellow Hens*.—First, W. Smith, Halifax. Second, P. Eden, Salford. Highly Commended, H. Brown, Sheffield; J. Hnie, Glasgow. *White Cocks*.—First and Second, P. Eden, Salford. Highly Commended, W. Kelsey, Halifax. *White Hens*.—First, P. Eden, Salford. Second, G. Ure, Dundee. Highly Commended, G. Ure, Dundee; S. Shaw, Stainland; S. Robson, Milford Junction; W. Kelsey, Halifax. (An excellent class.) *Dun or Mottly Cocks*.—First, W. Smith, Halifax. Second, J. Hnie, Glasgow. Very Highly Commended, —Stuart, Glasgow. Highly Commended, W. H. Penderic, London; T. Ridpath, Manchester. *Dun or Black Cocks*.—First, T. Ridpath, Manchester. Second, H. Brown, Sheffield. Highly Commended, C. J. Samuels, Manchester. *Any Colour*.—Medal, W. Smith, Halifax (White). Highly Commended, M. Stuart, Glasgow. **COCKS.**—*Black Cocks*.—First, F. C. Stevens, Axminster. Second, J. Bairstow, Halifax. Highly Commended, J. W. George, Nottingham; W. Deakin, Waltham; J. Bairstow, Halifax. *Black Hens*.—First, P. Eden, Salford. Second, J. Wadsworth, Halifax. Highly Commended, J. Deakin, Sheffield; A. Evans, Salford. *Dun Cocks*.—First, T. Colley, Sheffield. Second, P. Eden, Salford. Highly Commended, A. Evans, Salford; J. Bairstow, Halifax; A. L. Silvester, Birmingham. *Dun Hens*.—First, P. Eden, Salford. Second, T. Colley, Sheffield. Highly Commended, J. Bairstow, Halifax. *Blue Cocks*.—First, T. Colley, Sheffield. Highly Commended, J. Bairstow, Halifax. *Blue Hens*.—First, T. Colley, Sheffield. Second, J. Bairstow, Halifax. Highly Commended, J. Bairstow, Halifax. *White Cocks*.—First and Second, J. Bairstow, Halifax. *White Hens*.—First and Second, J. Bairstow, Halifax. *Black or Dun*.—Silver Medal and Third, P. Eden, Salford. Second, J. Bairstow, Halifax. *Highly Commended*, H. Smith, Skipton (Dun); J. Deakin, Sheffield (Dun); T. Colley, Sheffield.

ALMOND TUMBLERS.—First Medal and Third, P. Eden, Salford. Second Medal, M. Stuart, Glasgow.

SHORT-FACED TUMBLERS (Mottles).—First, F. E. Else, London. Second, S. Shaw, Stainland.

SHORT-FACED TUMBLERS (Beards).—First, T. Hives, Nottingham. Second, S. Shaw, Stainland. Highly Commended, J. W. George, Nottingham; E. Archer, junr., London (Blue).

SHORT-FACED TUMBLERS (Balds).—First and Second, S. Shaw, Stainland. **SHORT-FACED TUMBLERS (Kites, or Self-colours).**—First, E. T. Archer, London. Second, S. Stott, Rochdale (Red Agates).

COMMON TUMBLERS (Mottles).—First, M. L. Fearnside, Huddersfield. Second, W. F. Entwistle, Bradford (Black).

COMMON TUMBLERS (Balds).—First, J. Septon, Prescott. Second, S. Stott, Rochdale (Blue).

COMMON TUMBLERS (Beards).—First, H. Beldon, Bradford. Second, A. Graydon, Halifax.

COMMON TUMBLERS (Self-colour).—First, P. H. Jones, London. Second, S. Shaw, Stainland.

JACOBS.—First, S. Shaw, Stainland. Second, J. T. Lawrence, Liverpool. Highly Commended, J. T. Lawrence.

TURKIES.—First, P. F. Cook, Chorley. Second, E. A. Hargrove, Birmingham. Highly Commended, W. F. Entwistle, Bradford. Cup, S. Shaw, Stainland.

BARNS.—First, J. H. Frame, Lanark. Second, S. Shaw, Stainland. **OCKS.**—First, T. Ridpath, Manchester. Second, H. Morris, London. Highly Commended, F. E. Else, London; J. Percival, London.

FANTAILS.—*Cocks*.—First, W. Taylor, Sheffield. Second, T. Ridpath, Manchester. Highly Commended, W. Vaughan, Middlebrook-on-Tees (White); E. Smith, Birmingham; J. W. Edge, Birmingham. *Hens*.—First, J. Hnie, Glasgow. Second, G. Goore, Liverpool. Highly Commended, E. Smith, Birmingham; J. W. Edge, Birmingham; H. Morris, London; F. G. Stevens, Axminster.

TRUMPETERS.—First, S. Shaw, Stainland. Second, W. H. C. Oates, Besthorpe, Newark. Highly Commended, S. Shaw.

HENS.—First and Second, H. Long, Beverley.

NUSS.—First S. Shaw, Stainland. Second, J. C. Brierly, Nottingham.

MAGPIES.—First, S. Briggs, Holywell Green. Second, C. J. Samuels, Manchester.

SWALLOW.—First and Second, S. Shaw, Stainland.

DRAGONS.—First, E. Parry, Halifax. Second, J. Wadsworth, Halifax (Blue).

ANY VARIETY.—First, Second, and Fifth, S. Shaw, Stainland (Spots, Russians, Shields). Third, E. A. Hargrove, Birmingham. Fourth, A. Evans, Salford (Hyacints). Highly Commended, G. Ure, Dundee; A. G. Brooke, St. Ives.

JUDGES.—Mr. James Millar, Camlachie, Glasgow; Mr. T. F. Charlton, Stanley, near Wakefield; and Mr. Thompson, St. Ann's, Southowram.—(*Halifax Courier*.)

MANCHESTER EXHIBITION OF DOMESTIC POULTRY.

DECEMBER 26TH—28TH.

For some years past Manchester has not held the position so densely populated a neighbourhood ought certainly to do in connection with our poultry shows. It appears that some seven or eight years back a number of poultry exhibitions took place at the Free Trade Hall, Manchester. As a whole they were well attended, and excited no small share of both local and public interest. As, however, from the dilapidations caused by the lapse of time, the authorities deemed it far more expedient to erect an entirely new building on the site of the old Hall than waste money on the never-ending repairs of the one then existing, it was taken down altogether, and from that time to the present no poultry show immediately connected with Manchester has taken place.

Perceiving how much attraction such meetings caused with the public, Mr. Jeunison, the spirited proprietor of the Belle Vue Zoological Gardens, situate only about two miles from the centre of Manchester, determined to hold an "inaugural meeting" on the just-passed 26th December, and two following days, also to carry out those exhibitions annually for the future. With the determination, if possible, to give the same a popular commencement, not only was a very liberal prize list offered by its projector, but the hitherto unknown proffer of all the receipts derived from entrance-money, was guaranteed as an addition to the published premiums for those who might prove the successful ones. The sum thus added was not by any means a trifling one, as the entrance per pen was affixed at half-a-sovereign. We must say, from personal knowledge, the funds thus derivable were to a farthing scrupulously added to the premiums. To by far the greater proportion of our readers the permanency of such an arrangement seemed more than problematical, and we confess it did appear an enigma even to ourselves, how such regulations could possibly be compatible with the supply of means for refunding the very considerable amount of outlay ever resulting from the efficient carrying out of such meetings. The explanation proved, however, more satisfactory than was anticipated. Belle Vue Gardens are devoted not only to the purposes of a very considerable collection of living zoological specimens, but also contain a somewhat extensive and very interesting museum, together with the most extended arrangements for boating, dancing, &c. The establishment also enjoys a large printing-office, for the publishing of its programmes of entertainment, employing a number of men (never idle) in this particular department;

whilst, again, even the gas is all made on the premises for the exclusive use of this place of entertainment. Being for home consumption only, of course expense is held altogether subservient to quality, and certainly not a few of our public gas companies would do well to take a lesson, as copyists, of the gas manufactured at the Belle Vue Gardens. It is remarkable for its cleanliness and purity under combustion.

But to return to the entrance-money being given up *in toto* as a diversion to the successful exhibitors, instead, as at other shows, being the means of providing the customary funds for payment of the prizes. Mr. Jenkinson, on the contrary, determined to pay his proffered premiums out of the admission-money received from visitors, combined with the no trifling amount that might arise from the sale among so many of an aggregate of refreshment, that to specify would appear (to all) as completely fabulous. This feature in the fresh idea of a poultry show is evidently quite inapplicable to our general meetings of like nature, held under customary contingencies, but at Belle Vue it proved the very opposite of a failure in a pecuniary view. The extraordinary value of the prizes, however, no doubt tended greatly to dishearten the gross amount of general entries in the respective classes, as an entrance-fee of 10s. per pen, with carriage to and fro as extras, prevented little men from entering the lists at all, where they naturally enough supposed that their chance of winning was a very remote one. From this cause only the entries proved barely four hundred pens. Acting on this surmise, the competition in some few classes was very trifling indeed; and in others, strange enough—although only in a case or two—all the specimens exhibited were much below par. As to the Exhibition as a whole, perhaps there never has been one where all the poultry came so truly to their pens, hardly any coops being vacant, or as an exhibitor said—"Ten shillings entry is too much to pay without you purpose really sending them, for few would willingly throw away half-sovereigns."

A new arrangement was here instituted—viz., to send direction-labels for the hampers to the Show with consecutive numbers, just haphazard as they came to hand, whatever might be the class of poultry they represented, or however numerous the pens by any one subscriber exhibited; even in this first instance the numbers for the Dog Show were intermingled. On their arrival a person was deputed to place on each label another number (in pencil), of the particular pen the fowls were to be placed in for the Show. This was devised to prevent the possibility of exhibitors and judges entering into any private correspondence beforehand, or "sending their numbers to the judges"—certainly a somewhat questionable mode of evincing even a hairs-breadth confidence in the one or the other. That this new mode led to irregularities is certain, but we heartily trust that some provision for the prompt and correct return to its owner of each particular pen is made to operate, that on the face of it, at first sight, is difficult to apprehend as practicable in detail or correct in theory. Our space will not allow us to enter into details respecting the poultry exhibited, save the unqualified remark, that perhaps never, as a whole, has there been so entire an exemption manifested of the presence of indifferent pens, or so excellent a display of first-rate ones. One regulation was most satisfactory—any winner could have plate prizes if he desired it. There was a large and varied display on view, all marked in plain and legible figures on attached tickets: each party could choose for himself the most useful article for his purposes, or have the money in full—it was purely optional, and thus gained high favour.

E. Hewitt, Esq., of Sparkbrook, Birmingham; C. Ballance, Esq., of Taunton, Somerset; and — Douglas, Esq., of Ranton Abbey, Stafford, were the officiating Judges of the Poultry and Pigeons.

DOEKINGS (Silver Grey).—First, Lady Julia Cornwallis, Linton Park, Staplehurst. Second, J. Smith, Breder Hills, Sedgemoor, Grantham. Third, F. Smaller, Stand Hill, Whitefield, near Edgeborough. Commended, R. W. Boyle, Dublin. *Cock*.—First, T. W. Hill, Heywood, near Manchester, (Second withheld.)

DOEKINGS (Coloured except Silver Grey).—First, Rev. J. F. Newton, Kirby-in-Cleveland, Stokesley Station. Second, T. W. Hill, Heywood, near Manchester. Third, H. W. B. Berwick, Helmsley, Yorkshire. *Cock*.—First, E. H. Garrard, Clifton House, Mickleton, near Broadway. Second, Lady J. Cornwallis, Staplehurst. Highly Commended, J. Copple, Eccleston, Prescot.

DORKING CHICKENS.—First, Lady Julia Cornwallis, Linton Park, Staplehurst. Second, E. H. Garrard, Clifton House, Mickleton, near Broadway. Third, T. Bambridge, Green Hill Cottage, Moss side, Manchester. Highly Commended, T. Stetter, Stand Hill, Whitefield, near Manchester. Commended, Rev. J. F. Newton, Kirby-in-Cleveland.

DORKING HENS (any variety).—First, B. Baker, Wyseby Hill, Kirtle-

bridge, Dunfrieshire. Second, E. H. Garrard, Clifton House, Mickleton, near Broadway.

SPANGLED.—First, L. Teabay, Falwood, near Preston. Second, E. Smith, Middletown. Third, C. Carrington, London. *Cock*.—First, R. Teabay, Second, J. W. Smith, Oundle, Northamptonshire. *Chickens*.—First, R. Teabay. *Hens*.—Prize, J. W. Smith.

GAME (Black-breasted Reds).—First, J. Stubbs, Weston Hall, Stafford. Second, J. Hudson, Everton, Liverpool. Third, R. Swift, Southwell, Soth, fourth, Fletcher, Stoneclough. *Chickens*.—First, J. Stubbs, Weston Hall, Stafford. Second, J. Fletcher, Stoneclough. Third, W. Cox, Brailsford Hall, Derby. Fourth, S. Burch, Blackpool.

GAME (Brown-breasted Reds).—First, J. Fletcher, Stoneclough. Second, T. West, E.leston, near St. Helens. Third, T. Burgess, jun., Burleydam, Whitechurch, Salop. *Chickens*.—First, J. Fletcher, Stoneclough. Second, J. Wood, Blain, Wigorn. Third, T. Burgess, jun., Burleydam, Whitechurch, Salop. Highly Commended, R. J. Robinson, The Nook, Ulverston.

GAME (Duckings or other Greys or Blues).—First, J. Fletcher, Stoneclough. Second, J. Hindson, Everton, Liverpool. Third, H. Worrall, West Derby, Liverpool. Highly Commended, H. Shield, Northampton Commended, R. Swift, Southwell, Soth, *Chickens*.—First, J. Fletcher, Stoneclough. Second, W. Stewarts, Gorton, near Manchester.

GAME (any other variety).—First, T. Burgess, jun., Burleydam, Whitechurch, Salop. Second and Third, H. Worrall, West Derby, Liverpool. Fourth, J. Fletcher, Stoneclough.

GAME COCKS (Black-breasted Reds).—First, J. Hindson, Everton, Liverpool. Second, W. Cox, Brailsford Hall, Derby. Third, J. S. Butler, Poulton-le-Fylde. Fourth, J. Fletcher, Stoneclough. Highly Commended, J. Holme, Knowsley, Prescot; J. Fletcher, Stoneclough. Commended, N. Grimshaw, Pendle Forest, Burnley. *Cockrels*.—First, J. Fletcher, Stoneclough. Second, J. Stubbs, Weston Hall, Stafford. Third, R. Gorton, Tottington Hall, near Bury Lane.

GAME COCKS (Brown and other Reds except Black-breasted).—First, W. Colyer, Nantwich. Second, J. Fletcher, Stoneclough. Third, T. Statter, Stand Hill, Whitefield. Commended, T. Burgess, jun., Burleydam, Whitechurch, Salop. *Cockrels*.—First, T. Burgess, jun., Burleydam, Whitechurch, Salop. Second, J. Fletcher, Stoneclough. Third, R. Carr, Leyland, near Preston.

GAME COCKS (White and Piles, Duckings and other varieties except Reds).—First, J. Hindson, Everton, Liverpool. Second, J. Fletcher, Stoneclough. *Cockrels*.—First, J. Fletcher, Stoneclough. Second, W. Cox, Brailsford Hall, Derby. Third, F. Worrall, Liverpool. Fourth, E. Roberts, Preston.

GAME HENS (Black-breasted and other Reds).—First, C. Barber, Broughton, Manchester. Second, G. Clements, Birmingham.

GAME HENS (Black-breasted and other Reds).—First, H. Shield, Northampton. Second, F. W. Redhead, Wheat Sheaf, Bolton-le-Moors. Third, T. Moss, Poulton-le-Fylde.

GAME HENS (Black-breasted and other Reds).—Prize, J. Fletcher.

COCHIN-CHINAS (Buff and Cinnamon).—First, T. Stretch, Marsh Lane, Bootle, Liverpool. Second, W. Copple, Eccleston, Prescot. Third, J. B. Walthew, Aughton, Ormskirk.

COCHIN-CHINA (Buff and Cinnamon).—First, W. Copple, Prescot. Second, J. J. Thomas, Garstang. Commended, E. Smith, Middleton.

COCHIN-CHINA (White and other varieties).—First, T. Stretch, Liverpool. Second, J. J. Thomas, Garstang. Commended, E. Smith, Middleton.

COCHIN-CHINA (Cinnamon and Buff).—Prize, T. Stretch, Eccle, Liverpool. *COCHIN-CHINA (Cinnamon and Buff).*—Prize, E. Musgrove, West Tower, Aughton, near Ormskirk.

COCHIN-CHINA (Brown and Partridge-feathered).—First, T. Stretch, Liverpool. First, E. Smith, Middletown, near Manchester. Second, E. Musgrove, West Tower, Aughton near Ormskirk. Commended, E. Tudman, Whitechurch.

COCHIN-CHINA (Brown and Partridge-feathered).—First and Second, C. Tudman, Whitechurch, Salop. *Chickens*.—First, J. B. Walthew, Aughton, Ormskirk. Second, T. Stretch, Liverpool. Highly Commended, C. Tudman, Whitechurch, Salop.

COCHIN-CHINA (Brown and Partridge-feathered).—First, T. Stretch, Liverpool. Second, E. Tudman, Whitechurch, Salop. Highly Commended, J. B. Walthew, Aughton, near Ormskirk; J. Staley, North Collingham, near Newton, Houghton, Mirfield.

COCHIN-CHINA (White and other varieties).—First, W. Dawson, Hopton, Mirfield. Second, R. Chase, Moseley Road, Birmingham. Third, G. C. Whitwell, Kendal.

COCHIN-CHINA (White and other varieties).—First, R. Chase, Birmingham. Second, W. Dawson, Hopton, Mirfield. *Chickens*.—First, W. Copple, Eccleston, Prescot. Second, R. Chase, Birmingham. Highly Commended, W. Dawson, Houghton, Mirfield.

HAMBURGINS (Golden-pencilled).—Third, Messrs. Carter & Valiant, Poulton-le-Fylde. Fourth, R. Carr, Leyland, near Preston. (This class being decidedly bad, the First and Second prizes withheld.) *Chickens*.—First, F. Hardy, Laister Dyke, Bradford. Second and Third, J. Munn, Heath Hill, Stacksteads. Fourth, W. Whiston, Langley, near Macclesfield.

HAMBURGINS (Golden-pencilled).—First, Carter & Valiant, Poulton-le-Fylde. Second, E. A. Wainman, Birmingham. Third, W. C. Worrall, Liverpool.

HAMBURGINS (Silver-pencilled).—First, J. Dixon, Bradford. Second, D. Harding, Middlewich. (This withheld.) *Chickens*.—First, or Highly Commended, J. Fielding, Newchurch. Second, R. Hemmingsway, Shelf.

HAMBURGINS (Silver-pencilled).—Prize, Rev. T. L. Fellows, Beighton Rectory. *Fullets*.—Prize, N. Marlow, Denton.

HAMBURGINS (Golden-spangled).—First, W. R. Lane, Birmingham. Second, H. W. B. Berwick, Helmsley. Third, S. H. Hyde, Ashton-under-Lyne. Fourth, J. Dixon, Bradford. *Chickens*.—First, S. H. Hyde. Second, N. Marlow, Denton. Third, J. Dixon, Bradford. Highly Commended, H. W. B. Berwick, T. Burch, Sheffield. Commended, J. Newton, Leeds.

HAMBURGINS (Golden-spangled).—First, N. Marlow, Denton. Second, R. Lees, Ashton-under-Lyne. Commended, W. C. Worrall, Liverpool; J. Bamforth, Holmfirth.

HAMBURGERS (Silver-spangled).—First, T. Dale, Middlewich. Second, J. Dixon, Bradford. Third, Rev. T. L. Fellows, Beighton Rectory. Highly Commended, R. Teby, Fulwood. Commended, J. Newtown, Silsden. **Chickens.—**First, J. Dixon. Second, Lady J. Cornwallis, Linton Park. Third, T. Dale. Fourth, J. Leech, Newcastle-under-Lyne.

HAMBURGERS (Silver-spangled).—Prize, Lady J. Cornwallis, Linton Park. **HAMBURGERS (Spangled-hens).—**Prize, J. Bamforth, Holmfirth. **Pullets.** Prize, S. H. Hyde, Ashton-under-Lyne.

POLARDS.—First and Second, J. Dixon, Bradford. **Chickens.—**Prize J. Dixon.

GAMM BANTAMS (Brown or Black-breasted Reds).—First, T. H. D. Baily, Biggleswade. Second, J. Camm, Southwell. Third, R. Swift, Southwell. Fourth, R. J. Robinson, Ulverston. **Cock.—**First, T. H. D. Baily. Second, J. Camm.

GAMM BANTAMS (other varieties).—First, G. C. Whitwell, Kendal. Second and Fourth, J. Camm, Southwell. Third, T. Taylor, Chesterfield. Highly Commended, L. J. Crossley, Halifax; E. Holdsworth, Leeds.

GAMM BANTAMS (Any other variety).—First, J. Camm, Southwell, Notts. Second, T. Howarth, Horwich, Lancashire. Highly Commended, L. J. Crossley, Halifax.

BANTAMS (Any other variety).—First, T. H. D. Baily, near Biggleswade (Gold-laced). Second, E. Hutton, Pudsey, Leeds. Third, J. Dixon, Bradford.

BANTAMS (Black).—Prize, H. N. Harrop, Andeshaw, near Manchester. Highly Commended, E. Hutton, Pudsey, near Leeds.

FOWLS (Any other variety).—First, R. Teby, Fulwood, near Preston. Second, E. Hutton, Pudsey, near Leeds. Third, W. Lawson, Hopton, Mirdfield. Fourth, R. Lees, Ashton-under-Lyne. Highly Commended, R. Hillkirk, Altrincham; J. Dixon, Bradford.

BEAUMA POULTRY.—First, R. Teby, Fulwood, near Preston. Third, T. W. Hill, Heywood. **Chickens.—**First, R. Teby, Fulwood near Preston. Second, Mrs. Scamson, Aylesbury, Bucks.

PHEASANTS (Any other variety).—Prize, J. J. Jones, Churton Lodge, near Chester.

PIGEONS.

CARRIERS.—First and Second, P. Eden, Salford.

POWTERS.—First and Second, P. Eden, Salford.

FAV-TAILS.—First, T. Ridpath, Rushmore. Second, J. W. Edge, Aston New Town, Birmingham.

AMONG TUMBLERS.—First and Second, P. Eden, Salford.

SCISS.—First and Third, J. W. Edge, Aston New Town, Birmingham. Second, E. Holdsworth, Cals, Leeds.

BALDS.—First, J. W. Edge, Aston New Town, Birmingham. Second and Third, T. Ridpath, Poplar House, Rushmore.

DOWLS.—First, H. Morris, Silversdale Lodge, Forest Hill, Kent. Second, G. Lee, Ardwick. Third, T. Ridpath, Rushmore. Highly Commended, N. Roberts, Ardwick.

JACOBISS.—First, C. J. Samuels, the Elms, Victoria Park.

TURBIS.—First, T. Ridpath, Rushmore. Second, W. Whiston, Langley, near Manchester.

ANY OTHER DISTINCT VARIETY.—First, A. White, Manchester. Second, W. Keen, Bignor Street, Cheetham Hill Road.

TUMBLERS.—Prize, W. H. C. Oates, Beechhorpe, Newark, Notts.

ARCHANGELS.—Prize, E. Holdsworth, 99 Cals, Leeds.

PALMS.—Prize, P. Eden, Salford. Highly Commended, P. Eden.

DRAGONS.—Prize, Lady E. Talbot, Knowsley, Prescot. Highly Commended, C. J. Samuels, Victoria Park.

FOREIGN PIGEONS.—Prize, Lady E. Talbot, Knowsley, Prescot.

TURKEYS.—First, J. Dixon, Bradford. Second, J. J. Jones, Churton Lodge, near Chester. Third, B. Barker, Wyeby Hill, Kirtlebridge, Dumfriesshire.

Pouls.—First, Rev. T. L. Fellows, Beighton Rectory.

GRESE (White).—First, Mrs. M. Scamson, Hartwell, Aylesbury, Bucks. **Goslings.—**Prize, T. W. Hill, Heywood.

GRESE (Grey and Mottled).—First, J. Dixon, Bradford. Second, T. W. Hill, Heywood, near Manchester. Third, Mrs. M. Scamson, Hartwell, Aylesbury, Bucks. **Goslings.—**Prize, R. W. Boyle, Dub in.

DUCES (White Aylesbury).—First and Second, M. Scamson, Aylesbury. Third, E. Vezzer, Cheshire. Fourth, T. W. Hill, Heywood. Highly Commended, J. Hall, Macclesfield.

DECKS (Rouen).—First, J. Holme, Prescot. Second, P. Eden. Third, H. Worrall, West Derby. Fourth, Mrs. Alston, Fleetwood. Fifth, J. Dixon. Highly Commended, W. Apple, Preston.

DECKS (Black and Indigo).—First, T. H. D. Baily. Second, J. Dixon.

DECKS (Any other variety).—First, T. H. D. Baily. Second, J. Dixon.

ORNAMENTAL WATER FOWLS.—First, J. Dixon, Bradford. Second, T. H. D. Baily, Biggleswade. Third, R. W. Boyle, Dublin.

RABBIT SCHEDULE.

As the Crystal Palace Poultry Show is one of the leading exhibitions of its class in the country, the arrangements that are there adopted, no doubt, serve as an example for the provincial shows to imitate and profit by. There is one part of their programme, however, which I conceive to be a serious omission, and that is the non-encouragement that is given to the breeds of the useful Rabbits—that is, those Rabbits to which a commercial value is attached. The Rabbit-schedule of the Crystal Palace begins with "The Longest Ears," and proceeding through all varieties of colour, such as "Black and White," "Yellow and White," &c., they come to "For weight," and every other variety is included in the one remaining class of "Foreign Rabbits." The tendency of such an arrangement is to encourage the preservation of distinct colours to the disadvantage of such varieties as Silver Grey, Angora, Alpine, and Himalaya, to which there is a great commercial value attached on account of their skins. It is not surprising, therefore, that the exhibition

in the class of foreign Rabbits should have been so meagre, and that the varieties I have mentioned were so scantily represented, as the inducement for exhibitors to send their animals and the chance of receiving a prize are so small.

I do not object to prizes being given for long ears, different colours, and for weight; but I think other varieties of greater value should not be left out. The Silver Grey or Chinchilla, the Angora, the Alpine, and the Himalaya, are all valuable—some, indeed, very much so, for their skins; and I think it a great omission in a Society professing the improvement of breeds, that these varieties are not specially and individually classified. Imagine, for instance, the Smithfield Club offering prizes for dun and white, black and white, or the longest-horned cattle, to the exclusion of what really constitutes the real value of the animal. It would not be more absurd than the plan adopted by the Crystal Palace Company in their schedule. I would, therefore, suggest, that in future all Rabbit schedules should include classes for Silver Grey or Chinchilla, Alpine, Angoras, and Himalayas. The additional expense to the Society would be a mere trifle, and the arrangement would be carrying out what is professed to be the object of all such exhibitions—the improvement of the useful breeds.—**QUIS.**

LATE BREEDING OF BEES.

AN incident of early or late breeding with a black queen came under my own observation on the 26th of November last, and agreeably to the request of "A DEVONSHIRE BEE-KEEPER," I forward you a description of the ease as I found it.

Having sent a few of my octagon boxes to a carpenter to get covered with nine bars and Woodburyed, I had a delivery of one on the morning of the 26th of November, and determined to have it occupied to test the Woodbury-bar. I caught a sunny blink about two o'clock of the same day, and set to driving one of my Stewarton-hives into the newly-covered one. While tapping away—my assistant pointing out sealed brood and a few straggling young bees nearly emerged from their cells—I caught a glimpse of her majesty, and gently assisted her up among the driven bees, she being as fine a specimen as I ever had the pleasure of witnessing, remarking at the same time to my assistant that she surely must have some of the Woodbury breeding in her veins. "Na, na," says John, "give me a guid breedin' black queen, and I'll back her against any description of Mr. Wudborough's Italians I have ever seen yet." On driving the remaining portion I found the sealed brood in the inner sides of the two centre combs, and would measure about 3½ inches each diameter.

I may mention that the bees of this hive for the first six or seven days have been making comb and sealing as vigorously as in the month of May, and to all appearance at the back window are keeping true to the bars; but circumstances occurring prevented me carrying on till the beginning of January, when I may say how it has fared with my first introduction of bees to my Woodbury bar-hive.—**STEWARTON APIARIAN.**

[I have to thank the "STEWARTON APIARIAN" for the foregoing, which, however, appears to be an instance of late breeding, as proved by the sealed brood and young bees nearly emerged from their cells, and which I should imagine would not be unusual in a northern locality, especially if the queen were young and fecundated late in the season. Neither should I be at all surprised if egg-laying were resumed forthwith, under the influence of the liberal feeding which will be required to enable the bees to fabricate combs and provision their hive during winter. In the case related by me no such disturbing influence was at work, but breeding recommenced naturally so early as the beginning of December, after the usual autumnal cessation had taken place. We shall be glad to learn the result of the "STEWARTON APIARIAN'S" experiment with the new comb.—**A DEVONSHIRE BEE-KEEPER.**]

DRIVING BEES.

I FEEL constrained to speak a word in favour of this most excellent plan of expelling bees from hives, with which I have had great and continuous experience. Col. Newman certainly errs when he says "it seldom answers." I affirm, on the contrary, that it answers admirably nine cases out of ten—nay, when properly managed and followed up it cannot fail to answer in every case where a well-filled and well-peopled hive is

operated on. Scarcely a summer passes that I do not drive every one of my stocks, often more than once. Fumigating I have tried again and again, but have abandoned it for ever in favour of driving. It may sometimes be used with good effect to dislodge the few bees that remain after the main population has been driven, but it is at best a filthy and troublesome mode of ejecting bees. To drive successfully, however, requires that the operator should know thoroughly what he is about, and be both patient and persevering, as well as fertile in invention, if the bees do not immediately "cut and run." Neither is it to be expected that they will surrender in every case at the first summons. Sometimes—generally I may say when the hive is full—up they rush *agmine facto*, queen and all, but there almost always remains a considerable number below; for Col. Newman is quite correct in saying that bees—those, at least, which happen to be tending the brood—are unwilling to desert them. Should this be the case, I drive them into another empty hive, compelling them to go, and they must and do after more or less patience and perseverance. I have thus sometimes collected the driven bees into several hives, all within the space of half an hour, which afterwards were immediately re-united, by dashing them out on the ground in front of the hive into which the major part of the population was driven. Of course I make ready for all this beforehand, collecting a sufficient number of empty boxes or hives for the purpose. But this trouble is by no means necessary in every case; indeed, it is seldom necessary except when the full hive is wanted for plunder or some special manipulation. If I secure the queen at the first summons I am generally content because the bees left in the hive are only too ready to follow her, and will entirely desert the old hive (all, in fact, but the very young recently hatched bees), in the course of twenty-four hours. It is only necessary to put the hive or box containing the queen into the place of the old stock, and to remove the latter a couple of hundred yards, leaving the entrance open, and they will fly out one after another, and rejoice her.

As to bees being irascible at such times, no doubt they sometimes are so in an unaccountable manner. But in ordinary cases, if you go the right way to work, are careful not to puff and blow upon them, and handle the hives gently, avoiding all jars as much as possible, you may go to work quite at your leisure, and scarcely a bee will rise. They are more irascible in autumn than in spring and summer. Any time before August, when they are in full work, they are mostly tame and peaceable. But some persons go about among them in a fussy, clumsy manner, knocking the hive or breathing upon the bees, which always irritates them. No wonder they are irascible under such circumstances; but otherwise, when the attack is made upon them scientifically, they are at first astonished, then terrified, after which *save qui pent* is the order of the day, and a stampede, like that at Bull's Run, follows. With all respect for apiarists who have written of their experiences, I have long been of opinion that Mr. Nutt was a "lumbag," and his system, boxes and all, a pretty delusion. His opinion upon driving I hold to be equally valueless. Having been wonderfully taken up with him at an early period, and wonderfully disappointed, as every one is who believes in him, I speak with knowledge.—B. & W.

HOW I BECAME AN OXFORDSHIRE BEE-KEEPER.

(Continued from page 268.)

JUNE 26TH.—The cast, a very large one, issued from age 6, united it to cast from age 1 (crossed it in fact), for there were drones and young queens on both sides; and the farther the families are bred apart, whether in animals or plants, for these occasions the more sure is the progeny to gain vigour, or the flower beauty and substance. But they must be of the same family. A wasp species will not cross with my bees; though a variety such as the Ligurian bee would, and then they would be continually crossed, or back to their originals in a picturesque way they most inevitably would go. People might explain to me how a hare would cross with a rabbit, and that a monkey is a man after all, till they were considerably black in the face; but it would not alter my conviction to the contrary.

July 4th.—A general massacre of the innocents—viz., the drones. Found a dead queen cast out from age 6; so no more swarming this year.

I cleared off the supers from the hives on the 6th of August; and I might as well have done so a fortnight or three weeks earlier for that matter, as the bees had ceased working in them from that time; and considering the wet July, the sycamore bloom mious, and the lime flowers sparse, with the further impress that each hive gave me two swarms, the following specified deprivations incline me to feel satisfied that my bees have done their duty. Age 3 filled two fig-draws; weight of honeycomb 11 lbs. net, and a Payne's straw super partly full 6 lbs. Age 2 filled one of Neighbour's flat-topped glasses 9 lbs., a small fig-drum 2 lbs., and partly another 3½ lbs. Age 1 began working in a breakfast-glass, and that was all. And I find my old original age 6's super-working powers are exhausted. So let it go, poor old hive! and I have won thus much satisfaction in giving it so long a trial that, beyond four years for the stocks to remain profitable, it is unadvisable to retain them. The two united swarms of the 5th of June filled two of my breakfast-glasses, and partly another 5½ net, and the united swarms and casts of the 13th and 14th of June worked me a Payne's super 11½ lbs.—in all 47½ of beautiful honeycomb fit to set before the Queen, and just possibly a portion of it will be set before Her Majesty.

On the first of the morning I visit my apiary. Whoever has the troubles of the world weighing upon him (I have had my share—more than my share I sometimes think), I advise him to keep bees, and to do the same thing, and not only in the morning early but at every opportunity; and I will answer for it, it will prove one of the best antidotes known against troubles. No persons can view their industrious and spirited movements without sympathetically becoming decayed out of themselves as it were. But that is not altogether what I was driving at. Cobwebs are apt to become woven around the hives and pedestals during the night; and a few long tail-feathers from a pheasant tied to the end of a stick, for the purpose of whisking away the webs on the first thing of a morning, will prevent many bees from being caught in them to arrive at an untimely end. My bees are very courageous, and do not care a jot about the plague of wasps we have been infested with this season since I placed on their winter entrances without the slides. I was induced to do so on the day that I took off the supers, as it was desperate work for the guards without them; and from the manner they immediately began fanning themselves and adjusting their antennae, they instinctively proclaimed to the wasps, "Who cares for you, now?" I had only four zinc winter entrances: therefore to the other hives I placed some small mahogany wedges, *redan* fashion, to contract the summer entrances, and woe be to any intruder who attempts to force his way there.

Next in order I will describe the way in which I "take" a hive, and the subject for illustration shall be my original age 6. I choose the middle of a fine day, and am careful to have all my materials, specified already, at hand; and when depriving these large hives of their combs, it will be necessary to have two large dishes, and two small tablecloths, to cover them with, into the bargain. I never use chloroform, puff-blow, or tobacco-smoke, and I am not ashamed to say that I detest the latter as much as ever the bees can do, and poor little animals, that is saying a great deal, seeing the effect it has upon them. No, I like to see my bees active and well in all my operations, when I go about them. Neither do I resort to driving them from one hive to another, as that operation once took me three hours to perform. "Clumsy fellow!" many will ejaculate, still it is a species of tomtomming I cannot spare time for. So on the 6th instant, at noon, I relieved the pan, &c., from the hive, and turned it over bodily, as I said ament cleaning the boards in the spring; but now I set the reversed hive upon *terra firma*, and with the honey-knife rehere the edges of the nearest comb from the side of the hive, cautiously propelling it, in order to allow the bees to get out of the way of the spud, which as they are vigorous and active they will presently do. Then work the comb backwards and forwards, meantime maintaining a gentle lifting-force, which will probably relieve it completely from the bottom. In extracting the first, sometimes the second comb, the horizontal phlema cannot be used; afterwards it is easily inserted. Exert the same caution with it regarding the bees, and giving them time to avoid it as much as possible. Brush off what bees remain about the comb with the wing into the hive, for the queen may possibly number one among them, and should she become whisked away out of the hive, a difficulty would be created antagonistic to the proper re-assembling of the colony together, which in my prac-

METEOROLOGY OF THE WEEK.—At Cluswick, from observations during the last thirty-five years, the average highest and lowest temperatures of these days are 41.5° and 30.9° respectively. The greatest heat, 53°, occurred on the 12th in 1832; and the lowest cold, 6°, on the 9th in 1841. During the period 135 days were fine, and on 103 rain fell.

THE BEST ASPECT FOR WINTERING FLORISTS' FLOWERS.

Y almost every calendar, book, or treatise that has to do with florists' flowers, such as the *Auricula*, *Carnation*, and *Pansy*, the direction given is—Place the frames which contain the plants in winter facing the south. Now, of the wisdom of this procedure I have had for some time very considerable doubt; and having now tried an opposite system for two seasons, hesitate not to say

that my experience entirely confirms my impressions. It may seem very early to speak of seasons when we are only now at the end of December, but I conceive that the two last months of the year are the most injurious to these flowers; for, let it be well settled, that their great enemy is not frost but damp. Frost we may guard against—frigi domo, mats, &c., enable us pretty well to do this; but the insidious approaches of mild, muggy, damp weather, are matters of far greater danger; you may open your frames, but it is only to let the damp air in, and black spot appears on your *Carnation* leaves, and the rot attacks your *Auriculas* before you knew that it even meant to come.

I do not attempt to enter into any physiological reasons as to why this is so, for I have ever found that (while unquestionably there is a physiology, true both as to animal and vegetable life), those who wish to adopt a certain line of conduct make their physiology so very plastic as to meet all their requirements; thus we have been generally told by doctors, that suppers are very hateful and destructive things; but I saw not long ago, that a very eminent physician had proved on the clearest principles of physiology, that they were the very reverse. (I wonder whether he is fond of that social meal himself.) But these following reasons induced me to try whether a northern aspect would not do as well, or better. 1. In the case of the *Auricula*, I knew that in its natural state it never gets a drop of water, or sees a gleam of sun, during the winter months; and though I could not go the lengths of some grower, who heaped snow on his collection until he lost it altogether, I yet felt they could not possibly get any harm from not having sun then. 2. In a southern aspect they are brought into alternate hot and cold fits. The bright sun thaws the frost, and then the cold nights, or days, as the case may be, again congeal the soil, and thus the roots of the plant are continually exposed to great changes of temperature, which are alike injurious to man, beast, or plant. Whereas, in a northern aspect, although your plants are, it is true, longer under the influence of frost (which when severe will pierce through all the covering you may put over your frame), yet that they do not suffer much from this is testified by last winter; for in the case of *Auriculas*, at

least, there never was a finer bloom than this season all over the kingdom, as they are not exposed to those changes of temperature which, as I have said, are injurious to their well-being. 3. An immense amount of trouble is saved in watering. In a south aspect you are constantly obliged to do this, and oftentimes with the fear, perhaps, of a frost succeeding it, for, of course, the warm sun soon dries the soil. Whereas in a north aspect I have left my frames for nearly three weeks without a drop, my plan being always to give them a good quantity, and not dribble it out. 4. In the case of *Auriculas*, at least, there is no shifting of frames. My present stage stands as it has done for nearly two years. A north aspect is the only one suitable for spring and summer, and by adopting it in winter, it is evident no change need be made. These reasons weighed much with me in adopting the plan, and I am happy to testify to its success. Of course there are other points to be considered before pursuing this plan. Mine is a very open and airy position: were it confined, probably it would not answer so well. Such points are often overlooked. I once remember a first-rate grower of *Auriculas* telling me he bloomed his in a southern aspect. On seeing his place my wonder ceased; for just in front of his stage was a magnificent Yew-hedge about 15 feet in length, which effectually shielded the rays of the sun from the plants, while they enjoyed the warmth of the aspect; and as he was desirous of having his plants in early for exhibition it succeeded well. These little matters, being often overlooked, cause great perplexity to persons who follow out the instructions of those who do not look at all points of the question. I have simply told the result of my experience, hoping it may be useful to some who, like myself, have not over-much time to give to gardening. D., Deal.

FACTS AND OPINIONS, PAST AND PRESENT, RELATIVE TO CROSS-BREEDING PLANTS.

Is this, then, to be really the busiest season for crossing flowers on record? I merely inferred it should be so from the writings of the cross-breeders themselves during the last twelve months, and from the seeming purport of the cross-examination to which they were exposed. One thing is certain: the last year was fruitful in the rooting-up of old prejudices which have been inseparable from the doings of cross-breeders, and the working of their immediate predecessors—the hybridisers—I mean the mystery in which both indulged for so many years with respect to their rules of crossing, if I may so express myself.

It is now a plain, positive, well-known fact that the hybridisers of the last generation carried their rules of secrecy beyond the bounds of strict honesty. They originated seedlings by their mystic art which they sent into cultivation under the sanction of the highest botanical authority of their day as genuine wild species which had been introduced from foreign parts in the usual way. That was before people discovered the value of cross-breeding, or the way to improve new races of plants. All that has been said of cross-breeders—and all true florists are nothing else in that line—is that they kept their art a secret

from the rest of the world; while the hybridisers took the advantage which their branch of the subject gave them to hoodwink their customers, and at the same time to put the cultivators of botany off their guard so far as led them to publish several hybrid plants as genuine species.

That was another great step backwards; the first being the one which prompted the belief in the possibility of making mule plants—a power which has not yet, at all events, been revealed to man. The responsibility of the doctrine of nullification, to make a new word, rests, assuredly, on the same shoulders which carried the mystery of hybridisation to the point of dishonesty. But then there is this to advance in their favour for deceiving the botanists on the subject of muling—they, the hybridisers, were deceived themselves. In their branch of the business nothing is more common than the production of barren seedlings in some of the families then under crossing, and their operation extended at that time no farther than the crossing of species, and, therefore, they could not know that barren seedlings could be effected, save between two of their species, and they must have been in earnest in their belief on that score.

Here, then, are a moral and a practical illustration of the necessity for keeping the relative labours of the cross-breeders and the hybridisers apart, and not mixing them up loosely in writing or in conversation. One whole generation has been deceived into the belief of the doctrine that mules can be obtained among plants by manipulation, through the baseless inference from the working or the hybridising of a few species taken from a very small number of genera, of which the Heath, the Geranium, and the Lobelia are the three principal defaulters. You might almost put the names of all the old Heaths, Geraniums, and scarlet Lobelias on slips of paper into a hat, shake it, tumble them out on the table, and take any two of each of them to obtain a mule seedling, or a plant which is altogether barren. But now-a-days the very same result is produced without the union of kinds at all; yet the hybridisers of the last generation must not, therefore, be stigmatised, seeing they had no knowledge of the facts which cultivation and crossing for the improvement of races have brought to light since their day. Nor must we yet look for the universal disbelief in the doctrine of muling amongst our seedlings.

It is strange but yet true, that it is less easy to give up a wrong idea than to adopt a new one, whether it be right or wrong. But those who will run the race for first-class seedlings during this next season, should well understand the conditions of the subjects for their experiments, and the results which practice has proved to be best, and avoid the errors which the same practice has shown to be untenable. Cross-breeders should also know the biography, as it were, of all the families which have hitherto been crossed successfully. The next step would be to get a clear insight of so many of the families, or parts of families, which are reputed to be fit subjects for the hybridiser. For when you come to new subjects for crossing, the hybridiser must first have his turn at them ere they are the proper, or rather the property of the cross-breeder.

Who is able, however, to give us the biography of all the families which have been successfully crossed? The first thing a biographer in this line would meet with is very perplexing indeed. There are so many apocryphal genealogies given by continental writers, that a conscientious man can hardly bring his mind to believe them when they state the truth, and in the home process we are almost all of us bound down to the merits of a few popular plants. There are not over ten or a dozen families to which a British crosser would think it worth his time and trouble to experiment upon; and I have so few materials to enable me to give an outline of such biography, that I can merely break the ice to-day and trust to the good offices of the gentlemen who have taken part and interest in our discussions on this subject, to fill up the schedule from time to time as the spirit of the times moves them.

It is not much over eighty years since the first experiments in crossing plants began in Germany, by Kolreuter, who made known his success and failures in the "Acts of the Petersburg Academy." He is, therefore, considered as the father of hybridisers, for cross-breeding is of more recent date. The plants with which Kolreuter was successful were principally of the genera of *Lycium*, *Digitalis*, *Nicotiana*, *Datura*, and *Lobelia*. Mr. Knight was the first cross-breeder in England, and he also made some experiments on hybridising. All his experiments on fruit trees, with a few exceptions, were on the cross-breeding model. His seedlings between the Siberian Crab and some Apples, were

hybrids or half hybrids. The rest of his seedling Apples and Pears, as far as I can recollect, were merely cross-bred, and he is certainly the father of cross-breeding, as Kolreuter was the father of hybridising. Dr. Herbert was in the field as both a hybridiser and cross-breeder nearly as soon as Mr. Knight, and the reports of their experiments were first given to the world through the "Transactions of the Horticultural Society of London."

Dr. Herbert was the first person who discovered the fact that mules or barren seedlings were more numerous from the hybridising process than from cross-breeding, and it is over a quarter of a century since he refuted the doctrine of mule plants altogether, and showed that mules first tumbled in from the union of two of the species nearest in affinity, and, secondly, from flowers which were not crossed at all; so that the refutation of that doctrine does not rest with me—I only confirmed it by my own practice.

Mr. Knight was the first person who advanced the doctrine or dogma, that a fertile cross was proof direct that the two parents were of the same species; and he assumed as a consequence that a sterile offspring was nearly conclusive evidence that they are of different species. Both these opinions have since been conclusively proved to have no foundation whatever.

Dr. Herbert was the first person who held the opinion that the production of any intermixture amongst vegetables, whether fertile or not, was presumptive evidence that the parents were descended from one common stock, and showed that they were referable to one genus. This opinion has not yet been practically refuted in one single instance, and as a sequence, we cannot have a real mule plant yet in cultivation. Show me a barren plant, the offspring of any two members, or species of two distinct genera, and then I shall have seen a real mule plant for the first time. The botanical world was, at that time, much divided on these intricate questions, which are simple enough in these days through a wide extension of the more popular branch of crossing flowers—that of cross-breeding; but in order to clear the ground for the investigations of the biographer of cross flowers, it is necessary these diverse opinions should be traced to their origin, to their effects on the minds of men, and to their having been proved to be right or wrong by subsequent experiments.

But I have another object in view in thus putting them—to see if they or any such opinions are yet held, or are thought to be fit subjects for discussing now; and every one is invited to add his or her views on every one of these subjects, if they are backed by trustworthy experiments which go to prove the part or side taken by the writer. More opinions are of little use in such questions.

One more vexed question, and I am through with this part of the subject. What is the analogy between plants and animals in their capacity to breed crosswise within certain limits? That was a bone of contention in science between forty and fifty years back. All theologies on living things, and more particularly ornithology and zoology, would need to be recast and remodelled before the question could be satisfactorily answered, was about the sum total of that controversy. Some said that certain birds and animals belonging to two different genera had crossed, and why not plants so far apart? No, said they on the other side; you must begin first and revise your lists of genera, and then if ever this subject is fathomed, we shall see if a perfect analogy between plants and animals is apparent, not otherwise. The meaning of all that was, that the classification of the various families was not quite according to Nature, that Nature had no mules, and if you spoke of the Spanish mule you were told the parents came of one stock.

The possibility of acclimatising plants was then all but the universal belief. Now, we acknowledge and have confirmed that the only mode of acclimatising a plant is to change its whole constitution through the process of crossing in-and-in with a hardy kind, which, by judicious selections from numbers of seedlings may be done, and still retain the looks of the original kind.

The *Crimm*, the *Amaryllis*, the *Gladiolus*, and the *Camellia*, were the first four families of plants which were crossed successfully in England. The two former were crossed as far back as the first years of this century, the *Gladiolus* as early as the battle of Waterloo, and the *Camellia* much about the same time. As late as 1820, the *Crimm* and *Hippocaster* were set down in botanical books as species of *Amaryllis*; but the experiments of Dr. Herbert proved them, about the same time, to have been widely different both from each other as well as from *Amaryllis*, as that race was founded by Linnaeus on the foundation of the

Belladonna Lily, and on these three races of the Amaryllid order the first clash of arms took place between botany and hybridisation. The Camellia was bred in-and-in from the first by Mr. Chandler, of Vauxhall Nursery, not hybridised, and to the present day I am not aware of any hybrid plants among them. For a long time after the introduction of Camellias there was only one source whence hybrid Camellias could be had. There was but one distinct species, then called *Sasanqua rosea*, and afterwards named *Maliflora*, and the varieties of *Camellia japonica*—the japonica itself being the single kind since then used as stocks to work the double varieties on. I am not quite certain, as I am only writing from memory, if Mr. Chandler did not raise some hybrid seedlings by the pollen of *Sasanqua rosea*; but there are plenty of witnesses to put me right there. *Reticulata* was the next and third species of *Camellia* in cultivation, and I am not sure if there is one hybrid seedling from it, or by it anywhere.

D. BEATON.

THE IN-DOOR PLANT-CASE.—No. 6.

(Continued from page 252.)

I WILL now give a few hints on raising seedlings in these tiny stoves. Mine was last year devoted for some weeks to the little seedlings, and I have found *Ipomæas*, *Passion-Flowers*, *Maurandias*, *Mignonette*, *Canariensis*, *Cobæa scandens*, *Sweet Peas*, *Balsams*, *Petunias*, *Mimulus*, *Fuchsias*, *Geraniums*, *Begonias*, *Capsicums*, and *Tomatoes*, to grow in it beautifully. I had others also, but I forget their names. *Cucumbers* and *Melons* I had not; but this year I hope to prove the success of the case with them, since the *Capsicums*, and *Tomatoes*, and *Balsams* I fancy must require quite as much heat as these—at least the hardier kinds for greenhouse or out-door management.

The heat requires to be rather high. My case was filled twice in the twenty-four hours during the seed time, and the degree of heat is easily varied for different pots and pans, by placing them deeper in the sand or higher, or by disposing empty flower-pots underneath the seed-pots conveying the hot air.

I am, on the whole, inclined to steep the larger seeds for a short time in warm water, to make them sprout more readily. The *Ipomæas*, and others as large, should be laid on lightly-shaken soil well drained with charcoal. The seeds never being sown within an inch of each other, and then being covered with a quarter of an inch of soil pressed lightly down about them, they may be kept as warm as 75° to 80° until they come up.

I find, however, that when once up the sooner these seeds begin to have less heat given to their roots the better they will thrive. I pot mine into four-inch pots, well drained, as soon as they are large enough to move easily, and then they are kept in the same warm case for a few days to settle. In potting any of these seedlings a little hole should be made in the soil, and holding the seedling, with a little earth attached, in this little hole, soil should be lightly, and very gently, shaken in, till full.

Balsams, again. They take a vast deal of water, and yet require, while young, very first-rate drainage. A pan well drained with charcoal does best for them, and I have tried a heap of charcoal in the middle, through which one could pour in water to the roots, without touching the stems. Most seedlings, however, do very well as long as the sand in which they stand is moist.

I have generally left on air all day, but closed the case up at night; the sunshine by day raising the temperature till it is higher than at night, in spite of the night-closing. Great care must be taken to observe the first sign of mildew, to remove the affected seedlings, and to give less water or more air. For all seedlings, perhaps the easiest way to water without touching the tender leaves and stems, and the best way, therefore, of avoiding damp, is just to sow round the edge, and leave a little pit in the centre of each pot.

Geraniums grow most charmingly from seed, and are

pretty even as very little plants. They should be sown carefully, as the little spiral stalk twists and untwists with wet and drags up the seed. I have generally cut off this stalk, and my seeds have come up well. *Geraniums*, too, are pleasant things in coming up very quickly, and their pretty foliage makes fair amends for their not blossoming the first year at all. They should be put into very little pots, and changed as the roots get matted, or rather begin to mat. The seedlings are very brittle and need most gentle handling.

Balsams should be potted on from one pot to another as fast as possible, just as the roots begin to fill the soil; but if there is only room for a very few special flowers, they may stay on, in a three or four-inch pot, till one precocious flower appears to show if it is double, and, therefore, worth preserving.

Mimulus is also a most pleasant thing to raise, for there we have greenhouse flowers out within three months. It does well even in a scorching London window, if in a double pot, standing in a saucer, kept full of water. Three or four plants together, look very pretty for their variety in a four-inch flower-pot. The smaller the pot in all cases, I think the sooner flowers appear; but it does not answer to make the plants look too stunted.

I think that a case quite devoted to seeds is best, for the short time they take to come off and settle in after the first transplantation. *Achimenes*, &c., might at the same time be started, and a four-foot case filled with seeds and tubers would give with common success an immense stock of flowers. *Primulas* may also thus be raised, as well as *Carnations* and innumerable other things; in fact, all tender seeds that can be grown in stoves.

Hardier things like *Canariensis* and *Sweet Peas* cannot be removed too quickly to a cooler place. *Ipomæas*, too, are better away very soon. I place mine in a cold frame, merely filled with shelves close to the glass, which move up and down to suit the size of the plants placed on them. If I had, however, all seeds of one class in a case together, I should regulate air and heat, by variations as to the water, and by taking out glasses. In fact, one end of the case naturally giving so much root heat, and the other end none, we have a fair chance of making our cases keep pretty fairly one thing with another—hardy things, and those far advanced at the cooler, the tenderest and least forward at the warmer end.

A little spoke of ivory like a flattish crochet-needle is the best thing to use for "pricking-out." The crochet-hook is also often, in many ways, most useful in disentangling plants.

Light for the forward seedlings is a most essential thing; and it should always be remembered that the quantity of water depends on quantity of leaves and roots rather than on much soil, which it simply soaks and spoils—that the absence of light should invariably be accompanied by a reduction of heat—and that thus, at night, the temperature should be always decidedly lowered for some four or five hours, to give the plants a rest—an absence of excitement, which is to them a sleep.—E. A. M.

REPOTTING ROSES—PRUNING DATURA CLO-RANTHA.

I SHALL be much obliged if you will inform me what is the best time of year to fresh pot *Roses*. I have not touched mine since they bloomed last summer. They are in a cold-pit and I intend taking them out, prune, and repot them, and place them in the greenhouse at the end of January. Is that right, and ought I to shake off much of the old earth?

I raised some *Datura clorantha* and *Wrightii* from seed last spring. None of the plants bloomed. Should I cut them down and repot them in the spring to make them bloom next summer?—“AN AMATEUR” (M).

[It is bad policy to prune and repot at the same time. The

Roses needing it should have been repotted in the beginning or middle of Sept. ember, removing a little of top and bottom soil, and picking out some from the sides of the ball, and using rich loamy soil and not too large pots. The plants might then have been pruned, any time after the fall of the leaf on to the time when it was resolved to start them into growth. Now, these Mosses had better be pruned, drainage examined, surface soil removed, and rich top-dressings given instead of repotting. We should do this at any rate with all intended to bloom early. You may nip off the points of the *Daturas*, and when they began to grow, repot them. Ours flowered last season, but not strongly. We expect they will do so next year. They are now merely kept from frost.]

STOVE PLANTS

THAT WILL BEAR CONSERVATORY TEMPERATURE—
FORCING LABURNUM.

HAVING, for the size of my stove and the requirements for it, more plants than I could conveniently accommodate, still unwilling to relinquish any of my old acquaintances, I could but resort, since space must be had, to the expedient of removing some to the conservatory or cold-houses. But here arose a question, Which must they be? Looking around in one of those abstracted moods all whose minds are fully exercised at times feel, my hand came into close proximity with the sharp-pointed leaves of the *Bonaparte juncea*; and, as Nature prompts us to guard against the second attack of a foe, judging from his robust appearance his constitution was sound, I decided (although "*Hortus Britannicus*" assigns it the stove and my worthy predecessors had allowed it these cozy quarters), on committing him to the companionship of my *Azaleas*, *Camellias*, &c. *Icosandria pendula*, *Ficus elastica*, and *Draecena terminalis* were alike turned out. In doing so I have not only in some measure given myself elbow-room, but done them an infinite kindness, which their growth of the past season fully testifies, and their present appearance bespeaks them far more at home than in the close atmosphere of a stove. I am not yet satisfied with this small relief, but shall, on the return of spring, select others and leave them during next winter in the conservatory for trial. Not having heard of the first-named plant in a greenhouse, I thought this might be of service to some of your readers who may possess it, and, like myself, have but one store in which he is required to grow during the dull months of winter Cucumbers, Beans, Vines in pots, collection of stove plants, Roses, Lilacs, Rhododendrons, Laburnums, and a host of other things for conservatory decoration, besides a regular supply of that generally esteemed (and all this season doubly so) vegetable, Asparagus. This house may truly, as "*N. H. P.*" says, be considered an *omnium gatherum*.

I will but add one remark. I am greatly surprised so seldom to meet with the Laburnum as a forced plant, than which nothing under ordinary treatment does better; and what, may I ask, can exceed the beauty of a Laburnum, with its mass of golden blooms towering above the crimson *Camellia* and the delicate *Azalea*? Truly do I prize them, and grievously disappointed am I should anything cause a lack of my favourites during February and the following two months, to add its charms to my conservatory.—O. B.

THE FARMER AND GARDENER COMBINED.

THE few remarks that I have made in THE JOURNAL OF HORTICULTURE were intended as leading-strings to the would-be "generally useful," and to open a market for a number of very useful young men, that otherwise would spend in a nursery at the pay of a labourer the very prime of their days.

Now, whether it be milking a cow or feeding a pig, it can be done profitably and unprofitably; and, before a man is competent either to assist the one or the other, he should himself learn how to do it profitably.

The market I allude to will be in the majority of instances single-handed, with, perhaps, the assistance of a boy to mow the lawn, wood, &c.; still, if William Robinson, or any one else, should find that they had outgrown their limited sphere, they will find plenty of room to expand, as larger situations will grow out of the smaller ones in proportion to their profitable management; and, as a matter of course, gentlemen will prefer the man that

understands both departments practically, in preference to the man that is acquainted with the one department practically and the other theoretically.—THE DOCTOR'S BOY.

TREATMENT OF GERANIUMS WINTERING IN A CELLAR.

I HAVE put away in a cellar a number of *Geraniums*; some planted in boxes according to the directions in this Journal, and others hung up by the heels. Many of the points are decaying. Should these be cut back as they decay? Should the leaves of *Geraniums* hung up be cut off like those that are planted? or is it sufficient to pull them off when quite dead?—B.

[The proper treatment of *Geraniums* which are hung up in a cellar, or planted in boxes or in a bed of mould in a cellar, is to look over them occasionally, and to cut off every moral which decays or damps; then to dust over the fresh cuts some very dry powder. Lime in powder is the best; but we use the finest ashes fresh from under the grate, which are nearly as good. If the leaves of hung-up *Geraniums* wither dry, we leave them till spring? if they damp, we pull them off at once.]

TREATMENT OF CHRYSANTHEMUMS AFTER BLOOMING IN A GREENHOUSE.

I HAVE about forty varieties of *Chrysanthemums*, half of them are large sorts and the others Pompons. They have just finished flowering in a greenhouse, and have been cut down one or two days since. They are throwing up a great many healthy suckers. Now, I want to know what is the proper treatment to secure fine plants for next winter? Should they remain in the greenhouse, or would they do in a wooden garden-frame on einders, with some mats for protection? The plants were all grown from cuttings last spring from Mr. Bird's nursery. Ought they to be grown from cuttings taken now, or would it be better to divide the roots, and when?—MANCHESTER.

[After blooming, all sorts of *Chrysanthemums* and Pompons will do much better than in a greenhouse, either in a cold frame or plunged close to a garden wall, to be covered with mats and straw in severe weather, as we had to keep them for many years. They do better if the balls are turned out of the pots, and plunged in some light stuff, not wet or dry. Two days before plunging them, however, the pots should be well watered, and they should not receive more water till the end of March. The glass should be off entirely every fine day the whole winter through, and every night too if one was sure of the weather. Heavy rain is worse for them than a little frost. The way they keep Cauliflower plants for spring planting is another good way for *Chrysanthemums*. The reason for such care is not at all for fear of frost killing them, but to nurse up the brood of suckers for making the best cuttings of them in April. After the best of them are made into cuttings the balls may be lifted, and each ball might be divided into so many pieces, according to its size, and all shoots which are then longer than 3 inches may be cut down to the ground, and the pieces planted in the open ground for three or four months. But the very oldest way is yet the best way of propagating them for private use—that is to say, get stout, firm, stocky, suckers, with 3 inches of rooted parts from the old balls at the end of March, and put them three and three in No. 48-pots to begin with.]

GEORGE STEPHENSON AS A HORTICULTURIST.

TO young men faltering or struggling with opposing difficulties, Stephenson's life gives lessons which should supply fresh vigour. No beginning could have been more humble than his; but he persevered. He had determined to learn, and he did learn. "To such a resolution as his, nothing really beneficial is denied." The whole secret of his success in life was his careful improvement of time, which is the rock out of which fortunes are carved, and great characters formed. He believed in genius to the extent that Buffon did when he said that "Patience is genius," or as some other thinker has expressed, when he defined genius to be the power of making efforts. But he never would acknowledge that he was a genius, or that he had done anything which other

men equally laborious and persevering as himself could not have accomplished. He repeatedly said to the young men about him, "Do as I have done—persevere."

"Every step of advance which he made was conquered by patient labour;" . . . "Whether working as a labourer or an engineer, his mind was always full of the work. He gave himself up thoroughly to it. Like the painter, he might have said that he had become great by neglecting nothing."

"He did all thoroughly and honestly. When a workman, he put his mind and energies into his work; and when a man, he put his conscience and character into it. The battle which he fought for the locomotive would have discouraged most other men, but it only served to bring into prominence that energy and determination which formed the backbone of his character. The leading engineers of the day were against him, without exception; yet he did not despair. He had laid hold of a great idea, and he adhered to it; his mind was locked and bolted to the results. "I put up," he says, "with every rebuff, determined not to be put down;" and it was this determined purpose which secured the triumph of the locomotive.

Towards the close of his life, George Stephenson almost entirely withdrew from the active pursuit of his profession as a railway engineer. At home he lived the life of a country gentleman, enjoying his garden and his grounds, indulging his love of nature, which through his busy life had never left him.

He took an active interest in horticultural pursuits, carrying into them the same inquiring and inventive spirit and the same determined persistence which formed so large an element of his character. He was now as eager to excel all other growers of exotic plants in the neighbourhood as he had been to surpass his native villagers in the production of gigantic Cabbages some thirty years before. He had a fine house built, 68 feet in length, and ainery 140 feet. The workmen were never idle about the garden, and the additions to the structures proceeded, until at length he had no fewer than ten glass forcing-houses, heated with hot water, which he was the first to introduce into that neighbourhood. At one of the county agricultural meetings he said that he intended yet to grow Pine Apples as big as Pumpkins.

The only man to whom he would "knock under" was his friend Paxton, the gardener to the Duke of Devonshire, and he was so old in the service and so skilful, that he could scarcely hope to beat him. Yet his Queen Pines did take the first prize at a competition with the Duke, though this was not until shortly after his death, when the plants had become more fully grown. His Grapes also recently took the first prize in competition with all England. He was extremely successful in producing Melons, having invented a method of suspending them in baskets of wire gauze, which, by relieving the stalk from tension, allowed nutrition to proceed more easily, and enabled the fruit to grow more freely and ripen thoroughly.

He took much pride in his growth of Cucumbers. He raised them very fine and large, but could not make them grow straight. Place them as he would, notwithstanding all his propping them and humouring them by modifying the application of heat and the admission of light for the purpose of effecting this object, they would insist on growing in their own crooked way. At last he had a number of glass cylinders made, into each of which a growing Cucumber was inserted. This restrained, the unwilling fruit yielded to his guiding hand. Carrying one of the new products into his house one day, and exhibiting it to a party of visitors, he told them of the expedient he had adopted, and added, gleefully, "I think I have bothered them now!"

He was unsuccessful in his attempts to keep bees. The cause of failure was a puzzle; but one day his acute powers of observation enabled him to unravel it. At the foot of the hill on which he resided he saw some bees trying to rise from amongst the grass, laden with honey and pollen. They were already exhausted, as if by long flying, and it then occurred to him that the height at which the house stood above the bees' feeding-ground rendered it difficult for them to reach their hives when heavy laden, and hence they sunk worn out with the effort. He stated the case to Jesse, the naturalist, who concurred in his view as to the cause of failure, and was much impressed with the keenness of observation which had led to its solution.—L., (*American Gardener's Monthly*.)

TO PREVENT NAILS RUSTING.—The rusting (and consequent loosening) of nails employed to fasten the branches of fruit trees, &c., to walls can be prevented in a great measure by driving

into the wall at the same time with the nail, and in contact with it, a small piece of zinc.—(*American Patent Office Report*, 1861.)

GAZANIA SPLENDENS AS A BEDDER.

AFTER all that has been said against *Gazania splendens* as not good for bedding purposes, I must still uphold it. With me here (north of Dublin), it has been the most attractive bed in the garden, admired by every one who saw it. They were planted out the third week in May, and from that time to the 12th of November it was the most showy bed in the garden. The chief thing to aim at is to get the plants on forward before turning out. In short, mine were in full flower when planted out. And as regards the closing up of the flowers, I had no occasion to follow Mr. Beaton's plan, for they were constantly open, although raining for days together, and so beautiful as ever, and not at all closing at nights. I intend taking it on a much larger scale next year.—E. WILSON, *Gardener to the Bishop of Kilmore, Canon.*

EDGES FOR WALKS.

WHERE gravel walks are made through lawns or edged with grass, would it not be a good plan to insert narrow strips of slate along the edges, so that the walk may be silted to fill the weeds without damaging the grass edge, the slate being just level with the gravel?—B.

[A better plan has been in use in some places, which is to lay narrow strips of slate flat under the edge of the turf along the walk; then the edge of the verge or turf cannot root out into the gravel, and no weeds will come that way—that is, from the rooting of the grass, and when the walk is silted the grass takes no hurt. The roller would either level your slate with the gravel, or else leave a rib of gravel there. You are aware, of course, that silt encourages weeds in some walks. It is an old saying, "Kill ten weeds with silt, and twenty weeds will come to the funeral."]

PRUNING THE PEAR TREE.

OF a few hardy fruits, there is, perhaps, none which is more generally mismanaged, with regard to pruning, than the Pear. In our prambulations through the country, we too generally find both espalier and wall trees encumbered with a thicket of long barren spurs, producing crops of most luxuriant breast-wood, which is annually removed, but to be succeeded by another equally useless growth of shoots. In most old gardens we find large Pear trees, which are mere sterile incumbrances, and it has often fallen to our lot to have heard the border or the climate roundly abused as the cause of unproductiveness, when the main fault has been the injudicious treatment which the trees have received from the hands of the pruner. Success in obtaining fruit must, however, after all depend upon favourable springs for the blossoms to open and set; but it is in the power of the judicious pruner always to have his trees in a productive state, just as much as the unskilful ones succeeded in perfecting their abortions.

We often find the Pear trained in the fan-shaped manner—a mode most ineligible for it. For wall trees there is no plan so good as horizontal training. We have ourselves adopted a mode which we find answers admirably; it is, to train a single shoot till it reaches the top of the wall, then two horizontal branches, and from these pendent equidistant branches on each side of the stem—thus (*Fig. 1*). We find that in all fruit trees the finest produce is yielded at the extremities of long branches, from the sap being more highly elaborated. This mode of training gives this advantage in an eminent degree, and the pendulous branches are very fruitful. Trees thus trained, and alternating with horizontally trained ones, have a most pleasing effect, both in a useful and artistic sense.

To balance the energies of his tree must be the great aim of the pruner; he must endeavour to arrive at the happy medium between weakness and excessive vigour, by

Fig. 1.

checking the strong and encouraging the weaker growths; and whatever the subject with which he has to do may be, he must ever bear in mind the importance of having no more shoots than can be fully exposed to the action of light; this, in our climate, is of an importance not to be overrated, seeing what a large proportion of dull, damp, sunless, suicidal days our summers are made up of. The continental gardeners, particularly the French, with all their advantages as to steady summers, and more genial suns, attach great value to reducing the amount of summer growth by timely pinching, or preventive pruning, and were the system, with root-pruning, more generally

or quenouille mode of training; fourthly, the pyramidal or modern French mode; these three modes comprising the most valuable and useful forms in which Pear trees are trained.

Fig. 2 represents a one-year-old or maiden Pear tree, which it is intended to train horizontally. To effect this, it must be shortened at the time of winter pruning to three buds, *a, a, a*, one of which is to form the central stem, and the other two the bearing side branches. The middle shoot must be trained perpendicularly, and the other two may at first be laid out at an angle of 15°, to be brought to a right angle with the main stem at the next winter arrangement. The following season our tree will be represented by fig. 3, and the centre shoot must again be shortened to three buds, leaving about a foot or 14 inches between them and the lower branches formed in the previous year; the buds not intended to grow should be rubbed off. If the central shoot grows vigorously another pair of horizontal branches may be obtained by pinching it at the proper distance, at midsummer. This is very desirable, as you thus get two sets of shoots for one, in the same space of time—an object of much importance in furnishing a wall. A repetition of this course of treatment will furnish the space allotted, whether of wall or espalier rail.

Fig. 4 represents a two-year-old shoot, with naturally-formed blossom-buds. The fruit of the Pear and Apple is produced upon short studs or spurs, which proceed laterally and terminally from the main branches. To have the branches regularly covered with fruit-spurs must, therefore, be the object of the pruner. In the second year after the shoots which are to be the bearing branches are formed, the buds along them will produce shoots which may be treated in two or three different manners, with the same object in view. The old practice was to allow them to grow a considerable length, and then prune them back almost to their base, but from the crowded confusion in which such wood had grown, the leaves could only imperfectly perform their functions, and instead of organising fruit-buds for another year, another crop of barren shoots was generally produced. It is now found more judicious to stop them when they have attained the length of 2 inches or 3 inches; the result of this is, that embryo fruit-buds are formed at the base of each shoot so treated. We have also successfully practised the following mode—namely, when the shoots have grown to 9 inches or a foot in length we break them through, leaving them suspended by a portion of the bark. The light that is admitted to the unutilised base-leaves increases their elaborative power, and the sap is partially repulsed at the fracture, to be expended in forming embryo fruit-buds, two or three of which will be found at the base of each shoot in the autumn

Fig. 5.

(see fig. 5). Careful root-pruning will always control vigour and tend to induce fruitfulness. A watchful eye must be kept to have the fruitful spurs short and close to the wall, without which caution they will elongate and look unsightly, exposing the blossoms to greater risk of injury from frost, by removing them from the shelter of the wall. In fig. 6, *a* represents a spur from which a fruit was produced last year. At its base will be

practised, the most happy results must follow. Having premised thus much, we will now proceed to explain:—firstly, the formation of the horizontally trained tree; secondly, the mode of bearing, and management of the spurs; thirdly, the pendulous

seen an embryo leaf-bud, *b*, to which it must be cut back; this will, in the ensuing season, become a blossom-bud; *c*, which

Fig. 6.

will produce fruit in the third year, other circumstances being favourable, and the process of shortening must again be repeated.

If spurs become long and do not indicate buds at their base, they may be cut back, leaving a shoulder (fig. 7), from which a bud, or buds, are almost sure to proceed in the following spring. These observations apply to the Pear tree whether against a wall, an espalier, a pyramid, or pendulous-trained tree.

The quenouille or tying-down system has long been practised in continental gardens, and it is one which was also adopted long ago in the garden of the Horticultural Society of London. From a central stem tables of shoots, at regular distances, diverge, and are trained down to a circular hoop, to

Fig. 7.

which their points are fastened; during the summer all the young shoots, excepting the leading one, are bent and tied down, to check luxuriance and induce the formation of fruit-studs at their base, to which, at the winter thinning, they are pruned back. We have practised this plan extensively, with the exception that we fracture the summer shoots instead of tying them down, for the good effect of which we again refer to fig. 5. The word *quenouille* is French, and signifies a distaff, in allusion to the shape of the tree.

Pyramidal training, as its name implies, presumes a tree to be in the shape of a cone, or pyramid; and to be perfect, it should be clothed with fruit-bearing spurs from its base to its summit. As it is the most natural form in which Pear trees can be trained, so is it also the most advantageous, by the very equal amount of light which is afforded to the lower, as well as to the upper, branches and leaves. It is of moment, in this sunless climate to adopt such a mode of training as will expose the largest surface of foliage to the direct action of the solar influence; and, next to wall-training, no other plan affords this advantage in an equal

ratio. Another great advantage is the economy of space, thus enabling the amateur, with a few rods of ground, to combine the multum of horticultural interest with the minimum of space. To those who would do this, we earnestly recommend the perusal of our friend Mr. Rivers of Sawbridgeworth's admirable little treatise, "The Amateur Fruit Garden." He strongly recommends Quince stocks for pyramidal Pears, and certainly, in situations where they flourish, they are excellent; but on many dry, gravelly soils they only languish and die, this stock requiring a strong, moist, unctuous loam to grow in. In such soil Pears or Quince stocks, root-pruned so as to become a mass of small hair-like fibres, and the shoots pinched on the plan of M. Cappe (see *Gardeners' Chronicle*) are interesting, satisfactory, and beautiful objects.

We will suppose a young tree planted to form a pyramid. In the first year it will put forth four or five young shoots. Select that which is most suited for a leader, and pinch the points of all the rest when they have grown to the length of 2 inches. Should they push again repeat the process, making occasional exception in favour of shoots which are too vigorous, and taking care not to pinch the shoots at the base of the tree so closely as those of the upper part, in order to induce the pyramidal form required. Sometimes the pinching severely causes the young shoot so operated upon to die off, and converts the embryo spurs at its base into shoots. This is, however, the exception rather than the rule, which is, that the shoots so pinched remain stationary and for a fruit-spurs at the base. A few of the shoots may require a little regulation by tying out when the tree is young, so as to insure regular shape.

The management of Pears as standard orchard trees has been so often explained, and is so generally understood, that we do not think it necessary to advert to it in this paper.

THE APPLE.

The Apple is so similar in its mode of bearing to the Pear, that it would be mere tautology to illustrate it. The mode of training, too, which is most generally in use (the horizontal) is common to both fruits, and need not be again explained. But, although this is the case, we are convinced that the pyramidal, or even the quenouille, mode, would answer admirably if the kinds were worked upon the dwarf or paradise stocks, and treated as directed for the Pear, both as to summer and root-pruning. Such little symmetrical pyramids of fruit are most interesting objects, and have the concomitant advantage of doing little injury to the neighbouring crops.

Some years ago there existed, in the garden of the Horticultural Society at Chiswick, a row of Apple trees (standards), the points of whose branches were pulled down by strings, and which were trained in the shape of a balloon; they were pretty and very fruitful. Other modes of training might be adverted to, but as many of them are more fanciful than useful, the reader is referred to Loudon's "Encyclopædia of Gardening," in which full descriptions will be found.

When treating of pendulous training, we omitted to mention the good effects of it on a number of fruit trees at Spring Grove, then the seat of Sir Joseph Banks. It was here, if we mistake not, that we first saw it adopted as a system, under the personal direction of that talented and erudite philosopher. His trees were trained up one side of a wall, over the coping, and down the other.—H. BAILEY, *Gardener, Nuneham*.

WALL BORDER FOR PEACHES.

I HAVE erected a wall for the purpose of growing Peaches and Nectarines, the level of the garden being 3 feet above the level of the ground on the outer side; the wall is built upon arches and the soil is a strong loam. I shall feel obliged if you will inform me if it is necessary to prepare a border by throwing out the soil, and placing at the bottom a quantity of stones or brick-ends for drainage. I wish also to know the best mode of making the border to insure good plants and fruit.—J. E. S.

[You ought to have stated what the subsoil of your garden consists of, and, also, whether it inclines to the south or any other quarter; or, perhaps, it is quite level. If you have a clay subsoil, then it will be absolutely necessary to remove the soil and place under it a layer of stones or brickbats at least from 6 inches to 9 inches thick. In the front of your border you ought to have a good open drain below the bottom of the border, and that bottom should incline to it so that all the

superfluous water in wet seasons should run down into the drain. Then, if the subsoil is clay, or even gravel, the roots of the Peach and Nectarine trees should be prevented running down into it; for, if they do, the trees will soon canker and whole branches die off suddenly. The best preventive for such a catastrophe is to lay upon the drainage a coating of concrete, 3 inches, made of lime and sand, made into mortar and well rolled. Whatever may be the subsoil, it is still advisable to form the border systematically in order to have healthy trees and good fruit. The soil you state is a strong loam. Soils of that character are naturally retentive of moisture, and that is another reason why you should drain the soil effectually in the manner described. The soil would be much improved if it was mixed throughout with old lime rubbish, bits of bricks, or small stones. Such a mixture would keep it open and allow the roots to run amongst it more freely. Stone fruits of all kinds do best and live longest in a calcareous soil providing it is of a good depth. Such being the fact, the addition of lime rubbish supplies a strong soil such as you say yours is, with that substance so useful to them.]

THE ROYAL HORTICULTURAL SOCIETY.

At a Meeting of the Royal Horticultural Society, Dec. 30, C. W. Dilke, Esq., V.P., in the chair, the Chairman addressed the Meeting on this occasion relative to the great loss the Society had sustained by the lamented death of its late President H.R.H. the Prince Consort, and read the spontaneous and gracious communication of Her Majesty to the Society, a copy of which appeared in our Number of last week. The following address of condolence to Her Majesty, prepared by the Council, and forwarded in the usual way, was also read:—

ADDRESS FROM THE ROYAL HORTICULTURAL SOCIETY TO THE QUEEN.

"MAY IT PLEASE YOUR MAJESTY,

"We, your Majesty's dutiful subjects, the Vice-Presidents and Members of the Council of the Royal Horticultural Society, humbly approach your Majesty in your deep affliction, trusting that our profound respect for the memory of His Royal Highness, our late lamented President, and our reverence for your Majesty, may entitle us to offer our tribute of condolence and sympathy."

"While, in common with our fellow subjects, we grieve the loss of His Royal Highness to the nation, and as the Consort of your Majesty, and while with others we respected and admired his character, the kindly courtesy which marked his intercourse with the Royal Horticultural Society had generated amongst its feelings of personal attachment, which are now followed by deep and heartfelt sorrow for his loss."

"In our late President we have to mourn one who—when the Society which we represent was on the point of extinction—raised, revived, and guided it through difficulties, which he alone would have enabled it to surmount, and it is with the deepest gratitude that we acknowledge our obligation to His late Royal Highness for assistance given at a period when he must have been convinced that laborious personal exertion on his part could alone restore this Society to prosperity."

"Although the present condition of the Society is such, that at the Gardens at South Kensington constitute a worthy monument of the genius and skill of our late President, we cannot but perceive that our work is not yet finished; and that while great difficulties have been overcome, much remains to be accomplished, and that we have to lament the loss of our President at a moment when his direct and fostering care are sorely necessary."

"We humbly assure your Majesty that it will be our unceasing endeavour to complete the various unfinished designs of our late lamented President, and that we feel, by executing them with fidelity, we shall best testify the profound respect we entertain for his memory."

"Whilst we bow submissively to the Divine will, we earnestly pray that He who has smitten may also heal, and that your Majesty may experience in this hour of bitter trial the fitness of those consolations which The Comforter alone can give."

The following, on which the reader's heart will furnish a just commentary, is a copy of an autograph letter from His Royal Highness the Prince of Wales to the Council of the Royal Horticultural Society:—

"GENTLEMEN,

"OSBORNE, DEC. 28th, 1861.

"Prostrated with overwhelming grief, and able, at present, to turn her thoughts but to be object, the Queen, my mother, has constantly in her mind the anxious desire of doing honour to the memory of him whose good and glorious character the whole nation in its sorrow so justly appreciated."

"Actuated by this constantly recurring wish, the Queen has commanded me to recall to your recollection that Her Majesty has been pleased to assent to a proposal to place a statue of herself upon the memorial of the

Great Exhibition of 1851, which it was intended to erect in the New Horticultural Gardens."

"The characteristic modesty and self-denial of my deeply lamented father had induced him to relinquish to present his own statue from filling that position, which properly belonged to it, upon a memorial to that great undertaking which sprung from the thought of his enlightened mind, and was carried through to a termination of unexampled success by his unceasing superintendence."

"It would however now, Her Majesty directs me to say, be most hurtful to her feelings were any other statue to surmount this memorial but that of the great, good Prince, my dearly beloved father, to whose honour it is in reality raised."

"The Queen, therefore, would anxiously desire that, instead of her statue, that of her beloved husband should stand upon this memorial."

"Anxious, however humbly, to testify my respectful and heartfelt affection for the best of fathers, and the gratitude and devotion of my sorrowing heart, I have sought, and have with thankfulness obtained the permission of the Queen, my mother, to offer the feeble tribute of the admiration and love of a bereaved son, by presenting the statue thus proposed to be placed in the gardens under your management."

"I remain, Gentlemen, yours,

"ALBERT EDWARD.

"To the Council of the Horticultural Society."

At a special meeting of the Council, summoned on Thursday, Jan. 2, to receive this letter, the following resolution was agreed to:—

"That under the lamentable and affecting circumstances in which the Council are placed by the irreparable loss which they, in common with the nation, have sustained by the decease of their late President, the gracious offer of His Royal Highness the Prince of Wales should be accepted, but at the same time he should be assured that they contemplate the loss of Her Majesty's statue with regret."

RETURN OF MR. FORTUNE.

We have the pleasure to announce the return to this country of Mr. Fortune from the East. He arrived in London on Friday last in excellent health, and has brought with him many rare and valuable plants, several of which will excite great floral interest from their being adapted for open-air cultivation. Among them are new Lilies, Convallarias, Primulas of extraordinary character, and a rich collection of variegated plants which have not hitherto been introduced.

ENTOMOLOGICAL SOCIETY'S MEETING.

THE December Meeting of the Entomological Society was held on the 2nd of that month, the chair being occupied by the President, J. W. Douglas, Esq. The alterations lately made in the Society's apartments have tended materially to the comfort of the members, and will have the effect of rendering the proposed removal of the Society to other quarters unnecessary. The Meeting was very fully attended, and many very interesting novelties were exhibited.

Mr. Barnard brought an extensive series of Coleoptera from Smyrna; and Mr. S. Stevens a beautiful collection of Butterflies formed by Mr. A. R. Wallace in the island of Mysol near New Guinea. The announcement with which he accompanied this exhibition of the probable return of Mr. Wallace from the islands of the eastern archipelago (where he has made such large and valuable collections in various departments of zoology), in the spring of next year, was received with regret, although it was stated that he would probably leave one or more collectors behind him.

Mr. Adam White exhibited some specimens of a species belonging to the Neuropterous genus *Mantipia*, of which a considerable number of specimens had been developed in the entomological-room of the British Museum, in a very remarkable *Wasp*-nest lately received from Monte Video, formed by *Myzopetra scutellaris*, a species which Mr. White asserted is a honey-gatherer. On a section of the nest being made, it was found to consist of nearly twenty combs formed of a papyraceous substance; and although no larvæ or pupæ of the Wasps were found in it, a number of the *Mantipie* were found alive, and which exhibited their natural ferocious habits, seizing and preying upon small insects offered to them. Mr. White also called attention to a small Beetle belonging to the family *Psephenidae*, and differing from every species hitherto known of that extensive family, in having two short horns in front of the head. Mr. White proposed to form it into a new genus allied to *Anthaxia*.

Mr. Machin exhibited a specimen of *Ethia emortualis*, a species of *Pyralide* taken in Epping Forest. The species is

rare in southern Europe, and only a single specimen had previously been taken in this country near Henley-on-Thames.

Mr. Waterhouse read a paper on the British species of the genus *Grapholpha* belonging to the Coleopterous family Staphylinidae. He also exhibited a specimen of *Ichnoglossa corticina*, a species of the same family hitherto unrecorded as British.

Mr. Francis Walker communicated a paper containing descriptions of new species of exotic Lepidopterous insects in the collections of Messrs. W. W. Saunders and Fry.

Mr. D'Urban exhibited a beautiful series of Lepidopterous insects formed by himself in South Africa. The collection contains a number of new species of Pieridae, Polyommata, &c.

A paper by Mr. R. Trimen, of Cape Town, was also read, containing descriptions of new species of Butterflies inhabiting South Africa, belonging to the families Satyridae, Lycaenidae, and Hesperidae. It is to be feared that some of these supposed new species have been previously published in Sweden by M. Wollengren.

The President announced that in compliance with a wish generally expressed by the members of the Society, the chair at the monthly Meetings would henceforth be taken at seven o'clock in the evening instead of eight o'clock as heretofore.

NEW BOOKS.

THE COTTAGE GARDEN.*—It has been said that an Irishman promptly undertakes to do anything and everything; that an Englishman is similarly self-reliant if well paid for the attempt; but that a Scotoman will undertake no work that he does not know he can execute well. The little work before us is no exception to this estimate of our northern friends, for Mr. Anderson has composed it excellently. It was originally a lecture delivered upon cottage gardening, was published at the request of his audience, and is now in its second edition. It gives concise correct directions for the management of the culinary vegetables, fruits, and flowers usually cultivated by amateurs in small gardens as well as the kinds to be preferred. It is a good and safe guide.

THE HISTORICAL FINGER-POST.†—This is a most useful book, but its title does not do it justice. A finger-post only points to what you want to arrive at, but in these pages are contained the very objects themselves. It is a very excellent collection of brief explanations of events and things in history, science, &c., which writers upon such subjects are obliged to suppose their readers understand. Thus such writers talk of "The Seven-years War," "The Ban," Argentine Republic, Sibir, Elixir of Life, Patient Grizel, Catching a Tartar, Dies Irae, Jesuits' Bark, Bambee, &c., &c., and nine out of every ten readers proceed without knowing, though they wish to know, and must know before they can understand the subject thoroughly, what those events and things are. Now this book explains what they are, and we strongly recommend it to our readers as a cheap mine of useful information.

GENERALLY USEFUL CULTIVATORS.

(Continued from page 191.)

COW-MANAGEMENT.

I MUST suppose there are many readers of THE JOURNAL OF HORTICULTURE in situations similar to my own; some, doubtless, much better acquainted with the subject in hand than myself. Others there may be not so well acquainted; and it is to them that these preparatory remarks are intended, or to such as may from time to time enter their ranks.

It has been frequently stated by your able writers, that it is not the vast amount of knowledge that is required to be successful in this or that undertaking, but the diligent and proper carrying out the knowledge already obtained and the knowledge daily acquired. In these days of railroad travelling the commercial man must be systematic and punctual. When he leaves

* *The Cottage Garden, and How to Manage It.* By James Anderson-Meadowbank. Edinburgh. London, S. O. Briston.

† *The Historical Finger-post, a Handy Book of Terms, Phrases, Epithets, Cognomens, Allusions, &c., in Connection with Universal History.* By E. Sheiton. London, Lockwood & Co.

his hotel in the morning, he knows his business must be done by such an hour, otherwise he loses the train to his next town of business, which involves another night's expenses, reduces the profits for the day, and disarranges the next day's advices. So it is with the gardener, generally useful cook, and maid of all work. "The soul of business is punctuality;" and the man that wishes to make his undertakings pay must keep railroad time.

Yes, and the clergyman and the doctor in every village, and the merchant and manufacturer with residences in the country, can farm their few acres of land, deriving all the advantages of country life, and make it pay; and the gardener, either single-handed or otherwise, can take the whole management on his own responsibility, and his master will pay him for it.

We will suppose a gentleman struggling on with the difficulties generally complained; and John Jones the gardener, having picked up a pair of magnifying-glasses, and, trying them on, fancies he can see objects plainer than heretofore, says to his master that, with his permission, he will undertake the management of the whole by placing the odd man or boy at his disposal. And we must suppose that there are two at least, if not three cows (and there is more advantage in keeping three cows than two if there is land sufficient); and although there is plenty of grass in most places, yet he gives the cows a little hay at milking-time morning and evening, but let it be eaten up clean each time. If you do not find any increase in milk there will be an increase of cream, and the butter will be of a better quality, and the cows will be much healthier. If the hay is at all brown in the middle of the rick, give the cows the outside—it is better for milk cows, and let the coachman have the brown for his horses, you will please him by so doing. Should your fields be small, and one of them lies dry and sound at bottom, and if facing the south the better, keep the cows out of that as much as you can. If the spring should be at all favourable the young grass will soon spring up with the old, and the hay that is used now will be sared in the spring, and then you can turn out the first cow that calves. The cows can be changed to advantage in the other fields as often as you like.

The man, perhaps, is an indifferent milker, but here practice will make perfect when you understand the theory; and the theory that I shall teach will be nothing more than I practise. And I would wish to impress upon the mind of the milker that cows (like almost everything else), are just what they are made to be by the treatment of their attendant; and if one uniform kind of treatment is pursued it soon becomes a habit, which is not in all instances desirable. I knew a young cow that had been accustomed to be milked the first out of eight or nine; and being a little potted by the one that always milked her, she got at last that if by chance or design either of the others was commenced first, she would go straight and drive the cow away (they being all loose in a barn). It was necessary to break the rule, and the cow soon forgot it. Kindness is in all ways commendable, but there must be a degree of firmness with it. I tie up the cows during milking; and before putting the pail under the cow I rub the udder well with the hand. It is a cleanly habit, as sometimes from the cows lying down, or in the summer getting into muddy ponds, dirt gets attached to the udder; but I think there are other advantages.

On commencement do not wet the teats with the milk, as is generally the practice. You will be able to milk quite as well without it, and it is a dirty habit to say the least of it. More sore teats arise from this one practice alone than from all other causes. In the summer the teats are saturated with the oily milk, and directly the cows are out of the house the flies are swarming round their udders. The cows with their rough tongue lick them off, and in a short time the skin gets broken, the teats become sore, the cow does not stand to be milked, often upsetting a portion of it, and as often not properly milked out, and, as a matter of course, the quantity of milk decreases. In the winter, the teats being wet, and during frosty weather, the same effects are produced, and the same consequences follow. Having proceeded so far, press your head tight against her flank, making her stand in a proper position, so that you can get at the hinder quarters with ease. Then begin milking, and milk away as though you were determined to do it in so short a time. Use the whole of your hand as much as possible till the very last drop, and not dally over on cow strapping with the finger and thumb the time you ought to have milked three. It is not the waste of time so much as the bad habit the cows get into in not giving their milk down.—THE DOCTOR'S BOY.

A FEW DAYS IN IRELAND.—No. 9.

LOUGH CREW.

(Continued from page 257.)

THE plantations are admirably planted, and managed alike for ornament and profit. Crossing the park southwards from the flower garden, with grass far above the ankles (and which in moderate winters Mr. Stewart, the land-steward, assured us the cattle relished better than hay), we entered a fine wood enlivened with drives. On a precipitous corner a fine rockwork had been formed in times gone by, but now too much shaded by overhanging trees. In this wood, and especially by the sides of the drives, the Rhododendron was making a home for itself, and going on travelling and annexing more space as fast as it could. We do not recollect seeing the same travelling habit so fully in operation anywhere else, except at Bieton in Devonshire. The lower branches layer themselves naturally, throw up fresh shoots, which again root, and so the plant travels onward, until, if left alone, vast spaces would be covered. These drives in June must be magnificent. The soil seemed to be a rather stidish loam, adding another proof, if one were necessary, that this plant will hardly refuse any soil except that of chalk or lime. If we could have spared the time to go a little farther, we might have seen the lake from which the place takes its name.

We now retraced our steps along the valley by a nice walk to the kitchen garden, passing in our way a long row of old Yew trees, looking as if they had formed part of a terrace for some ancient building; and after noticing a few fine trees planted by the present Mr. Naper, some old thorns, and a huge tumulus opposite the garden, which we believe has not yet been dug into or explored, we reach the entrance gate in the middle of the garden on the south side, the garden being placed on the north side of the valley and sloping to the south rather steeply, the road to Old Castle passing its northern boundary. Before entering, we may state that this south wall is mostly covered with Jasmines, Roses, Clematis, and other elegant climbers; that at the south-west corner a rockery and fernery have been made, which will probably be increased, and the purling of a brook adds considerably to its advantages. The chief distinctions in the form of this garden are a fine walk with steps in the middle up the centre, with a Beech-hedge on each side, leaving room for a border of flowers between the hedge and the walk, and then crossing the upper squares by a diagonal walk, which thus gives more variety than if the ground was all in squares. A nice comfortable-cottage for Mr. Milroy, with three apartments below and three

- 15. Necessary-house.
- 16. Covered way to scullery, larder, and oven back doorway.

A few geometrical beds are shown on each side of front doorway.

The centre walk between the hedges is a striking feature, owing to a ribbon-border running up each side. The lower

these striped ribbons were narrow they were to us the most delightful thing of the kind we had ever met with in Ireland—partly owing to the charming background; partly to the regular gradation in height from the front to the back row; partly owing to each row being kept distinct by a thread and stakes in front of the back ones, but concealed, and yet quite close together without those openings which the engraver made in fig. 1, page 131; and partly to every row being perfect and full without a plant missing from end to end. At the break at the dial and steps a space is set aside for trying bedding Geraniums and other things, and nothing is used largely until thus tested.

Though not shown in the plan of the garden, all the cross walks, and side ones too, unless next walls, have a border on the side for espalier and dwarf trees, most of them as yet in a young state; and on several of these there are rows of Pinks, Carnations, Heartsease, &c, and some bedding plants. The two cross diagonal walks from the dial, if ribboned, would have a grand effect when you reached that spot from the entrance gate. I expect Mrs. Milroy will take the ladies' most successful means for having the walk so done that comes from the dial to her front doorway, and then our old friend will be obliged to do the other side, just to promote uniformity.

What! go back again to the old fashion of introducing flowers into kitchen gardens! Well, where there is room, we do not much care where we go to see the beautiful, and, provided as in this case, we are not compelled to look on flowers and vegetables at once. Besides, there is a great distance between these striped ribbons and the flower garden at the house, and there is nothing of the ribbon there; so that the style is altogether different. We believe some of the most effective ribbon-borders were made at Trentham in the kitchen garden.

A striking feature in these gardens are four Irish Yews, in the corners near where the cross walks meet, which average individually 19½ feet in height, and though very compact bushes average 14 feet in diameter of head. These fine plants were brought forty years ago by Mr. Naper from Florence Court, along with his keeper, groom, and dogs, all being driven forty miles in the mail phaeton. We understand that the original plant of all our Irish Yews is still standing on a hill of Fer-

borders are wider than those above, and there is a break where another path passes, and for a space on each side of the dial; but that is not noticed when you stand at either end, and of these ends we prefer to look up from the lower one. The lower half has five rows on each side; the first beginning with Purple Zinnia Dahlia next the hedge, then yellow Calceolaria, Scarlet Geranium (Improved Frogmore or Tom Thumb), Variegated Balm, and Lobelia speciosa (true) next the Box-edging, where it always tells when near gravel. The upper half was just the same, only being narrower, the Dahlia was dispensed with, and the yellow Calceolaria was the first next the hedge. Though

mough near Florence Court, and some 18 inches to 2 feet higher than these at Lough Crew. There are two trees still larger—one being more than 22 feet at Nethes Place, Mauchline, Ayrshire. Are any fine specimens known, grown only to one stem, and not branched from near the base?

The garden is beautifully and substantially walled all round; but, unfortunately, the stone is of so cold and moist a nature that the more tender fruits do not thrive against it. In olden times a thin wall of boarding placed in front of it would have remedied this evil, but in these days of cheap glass a house might be put up for not much more money for Peaches and Apricots, &c. Pears, Plums, and Cherries seemed to thrive admirably, and some trees on east and west walls of Ribston Pippin Apple, Newtown Pippin, and others, were well supplied with fruit, though here, as elsewhere, Apples and Pears were scarce this season.

The garden was well supplied with all the smaller fruit and vegetables, except Asparagus; this had pretty well beat Mr. Milroy. Some twenty years ago the garden produced good Asparagus; but the gardener, who was successful then, when he made fresh beds could not get the plants to grow for the life of him; and every gardener afterwards has been pretty well in a similar fix, though every conceivable plan had been tried—deep trenching, salting, fresh soil, &c. We found some places where old beds were left alone because it was found young beds would not grow. We should like Mr. Milroy and some other friends to give us all the facts they can on this important subject.

The garden is sheltered well on all sides, and all the glass, consisting of vinerias, greenhouse, stove, propagating-house, Fern-house, and frames are, all enclosed by themselves, and the ground being steep, a little attention to drainage will prevent anything like an accumulation of water. We found here, as well as in the garden generally, everything clean and neat and in its own place, for which, indeed, there was ample opportunity from the number and variety of sheds, &c. A nice little fernery had been made behind one of the houses, and there seemed no reason why it should not have been continued the whole way. We found some excellent Grapes on young Vines, and making fine, round, short-jointed wood, and that of most of the best new kinds. Mr. Milroy was much pleased with Lady Downes', and Trencham Black, and Bowood Muscat. There were some fine bunches of all these. The vinerias are being thoroughly refurbished with fresh Vines by degrees.

d Drain.
e Concrete.
f Brick rubble.
g Border soil.

These vinerias, like most vinerias in Ireland, have a pit inside and most valuable things they are either when filled with fermenting matter or otherwise. Fig. 4 will give an idea of these houses, and the mode of renewing the borders. These borders are about 16 feet wide outside, and rather better than 4 feet inside. Both inside and outside the roots are prevented going further by a wall. The Vines are all planted in-ide, the front wall being built on wide arches. A drain runs in front the whole way and well sunk. On the bottom, but higher than the drain, are placed from 12 inches to 20 inches of stones, the larger at bottom and the smaller at top. On that some inches thick of concrete, and then 4 inches of broken bricks and brick rubbish, the finest at top, a little litter, and sods to keep the soil from running among the bricks, and then the soil is put on and the Vines planted. The outside border, however, is not made at once but in the course of several years, adding a bit of fresh as needed. We allude to the soil part. The bottom is all finished at once. Half of the space for the border

was not filled, but the turfy soil was so occupied by roots as to say plainly they wanted some top-dressing, and a little bit more added to the width. The wall inside helps to support the inner pipe: three pipes act as flow-pipes on the level, and one behind acts as a turn. The Vine-roots in forcing will be influenced a little by the heat of the pipes above them. A small stage is placed on the pipes, and a narrow path between that and the pit, for which too there is a moveable stage in pieces, so that pot Vines and other things may be grown below the general crop of Vines and in all open spaces, and fruited there and elsewhere, provided room and heat can be obtained.

This mention of pot Vines brings me to the admirable mode by which Mr. Milroy, when renewing a viney with new Vines, never allows the roof of the viney to be uncovered with fruit; but actually obtains more Grapes and of better quality than he could have had from the old Vines. Mr. Milroy, like ourselves, has grown Vines successfully by growing them from the bud one year and fruiting them the next; but he found that they required so much labour and trouble and bottom heat, and then yielded such a moderate produce, that even on the score of economy and profit combined, he found it better to grow two years instead of one. Our friend Mr. Burton, at Hatfield, had the finest crop of Grapes, in pots, from one year's growth we ever saw, and we regret we did not give an account of them and other things; but it is so difficult in the busy season to overtake half of what we wish to get at. Mr. Burton, though so successful, cannot be so without great care and labour, and a good amount of glass devoted to these Vines before they are fit to be hardened off out of doors. As stated above, Mr. Milroy finds it more economical to have two-year-old plants, and, consequently, prepares his plants accordingly.

The plants we saw with fine Grapes still uncut, were struck from eyes in 1859, and grown on in 1860. The buds were inserted in March in the usual way, potted off into four-inch and five-inch pots, and plunged in a hotbed in a frame, using fresh loam, leaf mould, a little sand, and some dried horse-dung rubbed fine by passing through the fingers. As soon as they require it, they are repotted into seven-inch, eight-inch, and nine-inch pots, and replaced in the frame again. When the roots are running freely and the plants are about 18 inches high, the pots are nipped out to make them stronger and bushier, the side shoots being stopped to one joint; and when the plant makes a fresh leader the pots are removed to the front of a pit, where the pot can stand as close to the glass, and the shoots trained as close to the glass as would be safe, and where the necessary heat can be given them. Plenty of heat and water, with a due proportion of air in bright sunshine, and less of heat and moisture in cloudy weather, are much attended to at all times. When the wood gets brown and firmish, the pots are moved to the front of a south wall out of doors, and when winter sets in they are moved to a safe corner where they may have a little light, and be protected alike from frost and artificial heat, and get neither wet nor dry.

About the new year they are pruned down to three or four eyes, and in March each plant is turned out of its pot, the crooks removed, one crook placed over the hole in the pot, a good handful of fresh soil over that, and then the plant goes back in the same pot filled up with fresh surcing, well watered, and placed along the front of a viney just shut up about 50°, and close to the glass, getting only a dash from the syringe until they break, when he disbuds to two, generally preferring two shoots to one, which come slowly but strongly from being broken in a low temperature. A small stake is placed to each shoot and tied gently. If when two shoots are decided on, and one comes stronger than the other, the strongest is stopped that the weaker may get more strength; many are grown with one shoot. When the roots are running into the soil at the bottom of the pots, and the shoots have made three or four leaves, the plants are trained to fourteen, sixteen, and eighteen-inch pots according to strength and kinds, placing them so that the ball shall be covered, and the pot not be much more than three-parts filled, which will allow of several top-dressings. The soil is much the same as for the borders—fresh turfy loam, leaf soil, lye rubbish, broken bones, charcoal, and a little horse-droppings. If bright sunshine comes the plants are watered; if cloudy, this is not done for several days. As there are, generally by this time, several houses at work, those intended to be earliest are put into the early stage, and the others into later ones, as on the stage over the pipes, and plenty of water when needed, and

all the sunlight possible are the chief things to be attended to. When the wood browns the plants are moved to a south wall, where, unless in dry autumns, they are not watered. They are housed in time, and kept from frost and wet until started into growth and fruit.

Our friend, in addition to many sterling qualities, has been more noted for a racy dry humour that has too much of the kindly about it to be satirical, than for anything that is generally styled eloquence; but he did get eloquent about these Vines and no mistake. "Talk of fruiting within the twelvemonth or sixteen months, have not I done it and got my four or five bunches? but what is that to keep a family going when you make a new viney? Now, from these larger pots and two-year-old plants I get my ten, twelve, fourteen, sixteen, eighteen, and up to twenty-two fair bunches, as I had this season in an eighteen-inch pot as you may see. Am I, indeed, so far behind for waiting two years? Look at the host of inquirers of how to cure bad Vines. Why do not they get Vines in pots and fruit them a year or two, whilst they get new Vines into new borders? If these pots do not bear too heavily the first season, they will fruit well a second or even a third season. The other year I took eight bunches from a fourteen-inch pot. In September, as the wood was well ripened, I turned the plant into an eighteen-inch pot, placed the pot against a north wall, placed some slates over the mouth slanting to throw the water past, surrounded the pot and covered it with leaves and litter, and protected the stem; and, in the spring, the pot was full of fresh roots, and the plant yielded a heavy crop the next season. This next season, having cleared out a house and fresh planted it, I will, about March, introduce about three dozen of these Vines, one row in front and another row farther up, so as to cover the roof; and thus I will not miss the crop of the old Vines."

It will be evident that by this longer time being given, the necessity of pits with less or more of bottom heat is greatly obviated. We have given such prominence to these Vines that we must next to pass by all notice of the store and greenhouse plants, with the expressed hope that such nice plants of moderate size will find a more suitable place for showing them off to advantage as they get older and larger. Among greenhouse plants there were, in addition to *Fuchsias*, &c., *Acacias*, *Aleandras*, *Aplexis*, *Boronia*, *Azaleas*, *Camellias*, *Chorozemas*, *Correas*, *Epacris*, *Eutoxia*, *Erica*, *Genetilis*, *Kennedias*, *Pimelias*, &c. Of fine-foliated stone plants, the best *Begonias*, *Caladiums*, *Cyanophyllum magnificum*, *Crotons* of sorts, *Draena* ditto, &c. Then there were some dozen of kinds of *Aclimenes* and *Gloxinias*, good plants of *Allanandas* of sorts, *Aphelandras*, *Ardisias*, *Clerodendrons*, *Combretums*, *Dipladendas*, *Franciscas*, *Gardenias*, *Ixoras*, *Luculia*, *Marattia*, *Medinilla magnifica*, *Stephanotis*, &c. Of Ferns, a nice collection of the finer kinds, though the plants are yet small, comprising the best *Adiantums*, *Grunnogrammas*, *Cheilanthes*; *Pteris*, such as *argyræa*, *aspericaulis*, *tricolor*, *cretica* *alba striata*, and a nice collection of *Lycopodiums*. A collection of hardy Ferns is also being formed.

We were glad to see that it was resolved to build suitable accommodation for the young men near the cart gate, which will be much more airy and free from damp than their present resid-nee. According to its size, we have every confidence it will be made as comfortable as Mr. Milroy's pretty cottage. The way in which under-gardeners are penned in many places in England even, cannot be known or thought about by the proprietors of the estate.

The Yew-hedge separating these ranges and frames is about 8 feet high, but it has a light appearance from uniform semi-circular openings being formed in it at equal distances near the top. In such a position it seemed an improvement to the solid hedge. Among the frames in the Melon-ground rats had been busy, and merely to satisfy their love of mischief. They sorely troubled us once with Peaches when hard as stones—not eating them, but carrying them off and making stoves of them. We had a very cruel thing done. We caught a gentleman in a trap, lighted a little straw and just singed him a little, brushed a little rat on him, let him out of the trap, and told him to be off. We did not see the semblance of a rat for some eight years.

There is a large mound in the compost-yard planted with shrubs and trees; and picking at it accidentally brought the men to a passage, which led them first to one chamber and then another, built of stones without any lime or cement, a large stone at the top acting as the key of the arch. Various surmises are adroit as to the object of such structures—interment,

concealment, &c. Future explorations may show some connection with the large tumulus referred to, or some old castle in the neighbourhood. R. FISU.

(To be continued.)

WORK FOR THE WEEK.

KITCHEN GARDEN.

As the weather is open and mild, all trenching and ridging ought to be pushed on as fast as possible. We would again advise, where drainage is necessary, to get at it without delay. When we see the agricultural world so alive to the benefits it confers on them, it is strange to hear amateurs lamenting over their pining Peach and Nectarine trees and bad crops, and making no effort to strike at the root of the evil. The very worst soil and situation may be improved by drainage, and wall trees of all kinds rendered fruitful by artificial borders. *Asparagus*, if the soil in the bearing bed should become dry, give it a liberal supply of water, so that it may reach the roots; the neglect of this particular is one of the principal causes of unproductiveness, the earth at the roots being very dry, while the top is kept moist by gentle waterings. *Carrots*, where young ones are wanted early prepare a slight hotbed for the purpose, cover it with leaf mould or any light soil to the depth of 6 inches or 8 inches, on which the seed is to be sown, and covered lightly with the soil. A little Radish seed may be scattered on the bed at the same time; but they must be drawn in a young state before they interfere with the growth of the young Carrots. *Lettuce*, where there is a scarcity of the autumn-sown, sow on a slight hotbed or in boxes in a forcing-house; to be afterwards planted into a frame. *Sea-kale*, as that which was covered first is cut, remove the pots or other coverings to that portion which is uncovered, so as to keep up a succession. The dung and leaves which have been previously used will serve the purpose again if a little fresh be added. Avoid getting upon or working the ground when it is in a sodden state.

FLOWER GARDEN.

On soils that are naturally poor, and where neither fresh mould nor decayed leaves can be had, a moderate dressing of old hotbed dung well decomposed will be useful; but this should be well mixed with the mould the full depth of the bed—say 18 inches, and not carelessly turned in and left in lumps near the surface; for in this case, as noticed before, a gross habit of growth will be promoted early in the season, and as the principal part of the roots would be near the surface in the manner the plants would soon feel the effects of dry weather; whereas, if the manure is well incorporated with the soil, no ordinary amount of dry weather will injure the plants after they once get firmly established. The digging of shrubberies for two or three years after they are planted is beneficial to the shrubs; but after that nothing should be done to disturb the roots near the surface, as the health and vigour of the plants depend in a great measure upon them. As the object in planting is generally to have a quantity of thriving shrubs for ornament, it is an imprudent practice to dig shrubberies, as the operation is not only highly injurious to the trees and shrubs in consequence of destroying a large portion of their most valuable roots, but it also destroys that harmony which should exist in all ornamental plantations. For example: a large shrub surrounded by dug ground, and a similar one on a lawn surrounded by grass.

FRUIT GARDEN.

Where young trees are intended to be planted, the ground should be properly prepared, and no trouble or expense spared to have it properly done, remembering that their future success will very much depend upon how it is effected. Make sure of thorough drainage; and where the subsoil is unkind it should be removed, and replaced with some good fresh loam. Dress the fruit trees that are infested with moss, lichen, &c. Prune, train, and tie in neatly all espalier trees, and clear away all refuse that will not readily decompose to the char-heap, there to be converted into a valuable manure. If frosts prevail stir up the soil well with the hoe or fork close under the walls or fences; such places afford a ready refuge for slugs and other vermin to hide in security. It would be advisable also to shake a little quicklime over the earth thus disturbed.

STOVE.

As soon as potting materials are in due order, a movement may commence among the Orchids and other plants; where

shifting is requisite, selecting those which show a disposition to grow.

GREENHOUSE AND CONSERVATORY.

Provide and store in a dry place a supply of heath soil, fibrous loam, charcoal dust, wood ashes, and any other charred refuse, leaf mould, cow and sheep-dung, as such composts will be useful in the coming season. If the weather is unfavourable for outdoor work, the pots out of use may be washed, tallies of all sizes made, also flower-stakes of all sizes, matting ties to be bunched in convenient lengths, and the plants that are not likely to require shifting to be surfaced with fresh compost. Camellias will now be swelling their buds, do not neglect to supply them with water, and attention should be given so that it is supplied in proportion to the activity of the growth of the plants. This remark applies equally to other plants.

PITS and FRAMES.

Carnations and Picotees to receive an abundance of air to ward off the attacks of mildew, which is most virulent in a confined atmosphere. Many of what are called the florists' flowers in these structures are more apt at this season to be injuriously affected by the weather than such as had been planted in good time in the open ground. The general stock to be protected in very severe weather, but above all to be protected from cold cutting winds; on all other and more favourable occasions to be freely exposed to atmospheric influence. Verbenas require to be kept tolerably dry, as they are more susceptible of injury from damp than from cold. If the soil of any plant is sodden with water it should be turned out of the pot, and the drainage examined, and no more to be given until it becomes dry, when sufficient should be given to wet the whole ball of soil.

W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

HERE, work much the same as last week, with the exception of protecting Broccoli, wheeling manure on spare ground, of which there is little, and among bushes and fruit trees. We make it a rule never to let a barrow go on a walk when it can be avoided; and, if they must be wheeled upon, to do so in frosty, or at least in very dry, weather. We have frequently seen more trouble in cleaning up after a wheelbarrow than would have been involved by a man carrying all that was wanted in several journeys. One secret of keeping places well and economically is never to make work needlessly, or to do work in such a way as to make two jobs out of it instead of one. There is a small heap of prunings by the side of a clean rolled walk, one man will carefully ery them off in a basket, and keep his nailed shoes off the path by walking on the inside alley, and cleaning his shoes before he leaves it; another will slap up a wheelbarrow on the centre of the walk, litter the walk with his careless handling; and, to leave things as he found them, want a broom, perhaps the back of a rake, to level the walk, and then hunt after a roller to make things look as he found them, which he can only thoroughly do by rolling the walk all over; and then ten to one he will think himself very ill-used if his thoughtlessness and carelessness are pointed out to him. Again, one man will water a house of plants at this season, so as not to spill a drop of water, or show that he has thoroughly cleaned the plants as he went along, leaving not a semblance of a weed or a yellow leaf to be seen, because all these are clapped into his apron or other suitable receptacle, so that such plants never do want what some are so fond of giving them—a regular day for cleaning and picking. Another man will dribble and inundate the floor, giving a fruitful source for future dampings and drippings, and will render that floor impassable by every dead leaf and flower being thrown down upon it to let you see he has been doing something—necessitating the sweeping of that floor, and generally either a fresh sanding or a fresh scrubbing, and thus make three or four jobs out of one; and then very likely feel very much inclined to ride a high-mettled horse, when some old stagers hint that that is not exactly the way either to do work well or to do it expeditiously. "Avoid making two jobs out of one" would be as important a maxim in these days for gardeners, as "avoid the first quarrel" is a valuable one for newly-married people.

Sowed a bed of Early Horn Carrots in a frame, and placed some Ash-leaved Potatoes in a little leaf mould in the Mushroom-house to forward them for growing in pots. All things con-

sidered, after trying many, we prefer this for early crops under protection in the open ground. We prefer it chiefly in the open ground because from a necessity of cropping hard the haulm is so dwarf that we can have the rows closer together; or, if wider, can have successive crops of Cauliflowers and Greens, &c., coming on between them.

FRUIT GARDEN.

Chiefly pruning, and nailing, and tying out of doors; and, in frosty mornings, wheeling burnt earth, charred vegetables, &c., among Strawberry-quarters, carting up the crowns with this material so as pretty well to cover them, which alike secures them from heavy rains, keen winds, and severe frosts, and then placing a layer of half-rotten dung from old hot-beds as a blunt ridge between the rows, which again will act as a little protection; and if wet weather ensue the virtues will be washed down to the roots. If the weather should prove severe will stick some small branches of Laurel or of Spruce between the rows of the tenderest kinds, as the Queen; but there has been no row-fit to require such treatment yet. Watered the pots in the Vine-pit, some of which of the Black Prince are coming into bloom, though the average night temperature as yet is little above 50°, but will be gradually raised from 5° to 10° more.

FLOWER DEPARTMENT.

Gave all the air possible in fine, sunny, mild days, by pulling off the sashes from cold-pits and frames to keep the plants small and robust, or from being so thick they would be sure to get drawn and so injure each other if allowed to grow much. In sunny frosty days gave air chiefly by tilting the back, so that the fresh air entering should be mollified by the warm air passing out. In cold dull days with the atmosphere several degrees below the freezing-point, gave no air at all, as, provided the temperature inside ranged from 35° to a few degrees more, there would be little or no growth, no accumulation of vapour to speak of, and the introduction of cold dry air freezing would in such cases do harm. The thermometer in such—nay, in all cases, should be consulted, rather than our own mere feelings. Last season I knew of one case of many hundreds of plants getting done for in a fine, sunny, frosty day. The owner was peculiarly happy that day, felt not a bit of a keen parching air, and, instead of giving a little back air just to prevent accumulation of too much heat about the plants, turned off some sashes and gave air back and front freely to others, and before shutting-up time in the afternoon the poor things were as much done for as if they had been held near a furnace. If the owner had recollected that if extra heat was avoided, the mere light and heat from the sun would never have drawn his plants, he might have avoided the unpleasant disaster. In a sunny frosty day we should give all such things less air, than in a close muggy day with the temperature about 40°, or even above it. In such cases too much air cannot be given back and front, provided damp and fog are excluded. When a higher temperature is required, as for forcing flowers, or stove or warm greenhouse, more care still will be required in air-giving, though the same principles will fully apply. The greater the difference between the outside and inside temperature, the less air should be given, provided enough is secured to give a change of atmosphere; and, here, again, less air will be needed in bright frosty weather than in warm dull weather. The sun will pretty well purify the air for itself, and instead of such cold draughts of dry air being freely admitted, it would be preferable to let the fire heat be greatly reduced. All forced plants, bulbs, &c., should be raised out of a hotbed and hardened off gradually before being taken to a colder place to flower in. Commenced training old and young Pelargoniums, the largest to bloom first, to have no more stopping or potting. The second lot to have any extra strong shoot stopped, that all may have equal strength, and very likely to be re-potted. Younger ones for late summer and autumn will be stopped and potted as needed. Turned out and re-potted Gloxinias to come in early. Large tubers had all the soil shaken from them and were placed in smaller pots, in sandy loam and peat and a little old dried cowdung, to be re-potted again as soon as each pot is full of roots. For fine flowers tubers as large as one's fist are not to be desired, they throw too many stems, and even when thinned do not generally bloom so regularly or finely as smaller ones. A tuber from the size of a walnut and upwards is generally to be preferred. Placed some tubers of Achimenes also in boxes, to be potted when fairly up and several inches in height. This plan enables the grower to arrange the plants better as to size and strength. Continued potting as opportunity offered, using

heated soil and a warm shed for tender plants. Proceeded digging flower-beds and shrubberies in these slight frosty days, as it saves all chance of hurting the grass-edgings, &c.—R. F.

TRADE LISTS RECEIVED.

Sutton's Spring Catalogue and Amateur's Guide for 1862.—This continues to preserve the same features as it possessed in former years—with this difference, that it now includes many novelties which are not to be found in the previous editions.

General Price Current of Kitchen Garden, Flower, and Farm Seeds of the Plymouth Seed Company.—From being a bulky pamphlet, and assuming somewhat of the features of a regular gardening book, this has now lapsed into a less pretentious form, and has the appearance of a respectable seedsman's catalogue, furnishing all the information that is requisite in a priced list.

Catalogue et Prix-Courant de Ballet Frères à Troyes (Aube). is a general catalogue of nursery stock, but principally of fruit trees and Roses.

Catalogue descriptif et raisonné des Arbres, Fruitières et d'Ornement d'André Leroy, à Angers (Maine et Loire).—This is a very full and very excellent catalogue.

TO CORRESPONDENTS.

* * * We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the "Journal of Horticulture, &c.," 162, Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

We cannot reply privately to any communication unless under very special circumstances.

LIME AND VEGETABLE MOUND (E. T.).—You puzzle us when you say that you have put 100 bushels of lime to your compost, and that the whole is not more than three or four wagon-loads. The lime must be in great excess. It will certainly not do you any harm. You do not tell us the nature of your soil, so we must conclude that your "grass land" is a leam, and the grass to be mown. We should apply fifty bushels of the mixture to an acre early in the spring.

AMERICAN FLIGHT (A Notice).—The Aphid lancifera has by this time retired for the most part down to the roots, and will not return to the stems till the spring. You had better scrub the tank with a hard scrubbing-brush moistened with spirit of turpentine, and repeat the application if any of the vermin re-appear in the spring. Remove the earth from about the roots and apply some guano now.

VINEY (H. S.).—We see nothing wrong in your plan. The dogs had better sleep a little, and communicate with a drain. The boiler we would not raise quite so high, but would have it highest inside. Unless you raised higher the wall bounding the fire you would have a difficulty in watering it as it is. The idea of supporting your sill on posts is much the same as you would see in a late Number is adopted by Mr. Nix at the house at present on the border of your tank. It is well outside you will see is the same as that adopted at Lough Crew by Mr. Stroy, only you have not got or shown his plan. The fire alone, if made strong enough, would be sufficient to heat such a house unless you forced very early; and even then we do not see how the fire should not be sufficient. You ought at least to have two openings in the apex of the roof besides. This would be more necessary if you forced early, as the stream of cold air from the ends might be too violent, and in very hot days the house would be apt to be too hot at the centre, and give you red spider in plenty on your Vines. We can only refer you to the subject of hot houses, your paper, &c. for the construction of them. The mode of managing such houses so as to secure a combination of results has been frequently given.

VINES TURNED OUTSIDE (E. T.).—Having taken your Vines outside your greenhouse a month since, and found hardships found them, it is of no consequence now whether you take your Vines into the house at present or allow them to remain bound up until the month of March—they will be quite secure so protected. We have repeatedly stated that for Vines in a greenhouse, there is no more necessity for taking their branches and leaves outside in winter than there is for an animal to leave his bed and stand out—a subject which is pretty well treated upon in our last issue, and prevent the cold from injuring him much. There is no danger of starting the Vines prematurely, if you do not give your house a higher average heat at night than 45°. If you were making a forcing-house of your greenhouse in winter, and wished your Vines to be late, the taking of them out would be all right; otherwise they are safer inside, and much better and trouble are saved. In

a cool temperature inside (40° to 45°), they will suffer no harm. Taking them out too early often injures the crop of the following year.

PLANTS FOR BALCONY AND WINDOW (Chelsea).—We should say that three parts of your exposed sandy clay, three parts of your exhausted sandy soil, and one part of your rotten horse-dung mixed well together, would grow all the plants you name, except *Abutilonstrans*. For them we would prefer the sandy clay alone well rammed round the balls, and then a coating of an inch of the rotten horse-dung, and, better still, cowdung on the surface. These may be put in any open weather before April, and will be quite safe if the pots are plunged and protected by litter. If the weather should be very severe before April, a few brackets may be stuck among the plants in the way of protection. We should have preferred sweet sweet bean for all with top-dressings, if it could have been had; though, for anything you say to the contrary, your compost may do admirably. All the common Vegetable Marrows will suit your purpose best, as you will have more weight of suitable matter from them than from larger monster kinds. The more you use of them, however, the more you will spoil the marmalade, as we fear is too often done. We hope the main article is for your own use.

NAME OF APPLE (Frank).—There is no Apple of the name you mention, nor of a name anything like it.

SEEDLING CINERARIA (Mrs. Tomlinson).—The colour is pleasing, but in form and substance about twelve years behindhand.

PREPARING YOUNG APPLE TREES (G. H. L.).—If the shoots of your young Apple trees are all well placed, allow them to remain and shorten them one-third.

GERANIUM (J. L.).—We do not recollect the Geranium in question. Can you refer us to the Number or page where it is mentioned?

LILAC AS OFFICE WOOD (Rev. F. Baker).—A very good suggestion and a copious of Lilac would be just as easily planted, and quite as cheap, as with Ash, Hazel, or any of the common office plants; it will grow on any soil, and is hardy enough for any situation from London to Vienna. London says there are hedges of it by the roadsides in the neighbourhood of Ulm, and Augsburg, a the elevated, and, consequently, cold region of Bavaria.

LIST OF PLANTS (A Subscriber, Stourbridge).—1, *Asplenium marianum*; 2, *Drosera* (or *Woodwarta*) *rotunda*; 3, *Asplenium trichomanes*; 4, *Fuchsia* *spicata* (*M. H. J.*);—1, *Cyrtanotum* *talictum*; 2, *Polystichum capense*; 3, *Campyloneurum angustifolium* var. *tanaisium*; 4, *Varietaria serpyllifolia* (*A. Innoctelle*);—*Acroclonium rostratum* (*E. H. F. M.*);—*Melanthus major* (*J. Wape*);—*Polypodium vulgare*, and two forms of *Polystichum aculeatum* var. *lobatum*. The specimens were not numbered. (*J. L.*, *Stourbridge*);—1, *Cerastium vulgatum*; 2, *Clinopodium vulgare* (*E. H. F. M.*);—*Scotopodium vulgare* var. *multifidum*.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

EGG-PRODUCING AND PROFITABLE FOWLS.

I HAVE kept fowls for about thirty years. Game fowls were my first start. I stuck to them for many years. White Dorkings next, then Grey Dorkings; then Buff Cochins, Black Cochins, and White Cochins; then White-crested Black Polands, and last, Silver-pencilled Hamburgs. About nine years ago I began cross-breeding; and the most profitable fowls I ever had was a cross between the Silver-pencilled Hamburg cock and White Dorking hen. They follow the Dorking in appearance—most of them five claws, white and blue legs, white and piles in colour, with sometimes one side of a feather in the tail or wing of a greyish-black. They have a ready sale in the market with the feathers on; or dressed, they are a nice sized plump fowl for a gentleman's table, and dress beautiful and white. They lay a tidy-sized egg, half as large again as that of the Hamburg, and the same size at both ends. They never attempt to sit; and I never heard but one cluck, and that for about a week; but she went on laying the same, only stopped a little longer on the nest when laying—and they will lay from nine to ten months without intermission, though the weather be bad. If they are hatched in the last week in April they will begin to lay in October and keep on till June, and some of them till July; and then when done moulting, they will begin to lay again in December or before, and lay as long as they did the first year and as well: so that by managing to have them of two or three different ages there is no need to be without eggs every day in the year. They are very great caterers for themselves. They leave nothing unturned that they are likely to find the smallest mite in; consequently they do not require and do not eat nearly so much as many others of the sorts I have mentioned. So, taking them in every way, they are the most profitable fowls I ever had or ever saw amongst any of my neighbours who have kept many more different sorts than I have; but I have always eggs when they have none. I have no doubt they would do well a third season, but I keep them but two. So if I was going to begin keeping poultry I should at once get some good maiden White Dorking pullets and a good square Silver-pencilled Hamburg cock and breed a stock from them, keep all the young cocks cleared off before they begin to interfere with the hens, so as not to have them crossed any further than that one cross.

I have crossed many other sorts, and given them all a two-

years trial, and have one sort now undergoing a third year's trial—and that is a cross between the Silver-pencilled Hamburg cock and White-crested Black Poland hen. Now, for laying there is nothing to equal them, let alone surpass, either in confinement or at large, and the egg is a great improvement on the Hamburgs'; so I advise a White-crested Black Poland hen or two to breed from as layers turned down with the above-named. And if laying was the only quality I wanted, I should make that breed the main stock, and have more Polands and less Dorkings. This cross, being non-sitters on either side, lay full ten months, and have the good quality of moulting all as it were by magic. They fall off in laying the last fortnight; and when they have laid their last egg, in a day or two you will see two or three feathers turned wrong side up, and next day perhaps hardly any feathers on them, the tails dropping all at once. In one night I have seen it and all the feathers come on all together. They are soon in full plumage and all right, and begin to lay again directly.

Then there must be a Silver-pencilled Hamburg hen to breed some cocks from to be reared up with the pullets, as the cross-bred cocks, as above stated, must be done away: neither must the cross-bred hens be bred from, and no other sort of cock introduced. By that means there will always be the true Silver-pencilled Hamburg breed, and the other crosses true to what they are intended to be; and with a good walk and proper feeding they beat everything in the poultry way that has come under my notice.—WORCESTER.

IMPERFECT DESCRIPTION OF POULTRY IN CATALOGUES AND PRIZE LISTS.

BEING a Game Bantam fancier, I find very much inconvenience in not being able to discover, not only in your list of prizes but also the catalogues, what the variety of the winning birds in "any other variety" and "Game Bantams cocks" are. In furtherance of this object, seeing that the utility and popularity of these shows have made them so frequent, it behoves a publication like THE JOURNAL OF HORTICULTURE to inaugurate a system of abbreviation so complete and intelligible as to meet with universal approval. Confining myself to Game Bantams, I would suggest for

Game Bantams	G. B.
Black-crested Red Game Bantams	Bl. E. R. G. B.
Ducking Game Bantams	Dk. W. G. B.
Piles	Pis.
Blood-red Piles	Bl. R. Pis.
Any other Variety	A. O. V.
Cocks	Cks.
Pullets	Pis.
Cockerels	Cks.
Hens	Hns.
1st prize	1.
2nd "	2.
3rd "	3.
Highly Commended	H. C.
Commended	C.

Many of these abbreviations are already in use with amateurs who mark their catalogues whilst at the shows, proving the call there is for such an adoption. If such a system was started by your valuable Journal, there can be no doubt but that the Societies throughout the country would follow your example in printing the catalogues; and when established, the prize lists as published by THE JOURNAL OF HORTICULTURE might be printed in columns—viz., one for number; two for name of exhibitor; three, address; four, variety; five, age; six, prize; and perhaps seven, price—how much more condensed, plain, and full would such a report thus abbreviated and tabulated be.

In conclusion, I beg to submit that Game Bantam varieties have equal right to be mentioned individually as any other variety have; and I am sure the majority of your readers will be obliged if through your advocacy this desideratum is supplied.—WEAR VALLEY.

P.S.—I do not mean to confine abbreviations to Game Bantams, but to all poultry, Pigeons, birds, &c.; and as the merchant writes free on bond by F.O.B., why not Game Bantams by G. B., &c.?

PRICES OF EXHIBITION POULTRY.

A CORRESPONDENT of well-known credibility informs us that the Marchioness of Winchester recently sold a Dorking cock and two hens for £41 before they were sent to the Exhibition at

Birmingham; and that in 1860 a gentleman offered her at the Show £200 for the three which won the cup at Birmingham. Her ladyship now has a Dorking cock for which she has been offered £23, but refuses to take less than £25.

SUTTON AND MACCLESFIELD POULTRY EXHIBITION.

THIS Show was held at the house of Mr. James Rowson Sheldon, "Old King's Head," Sutton, Macclesfield, on the 3rd and 4th inst. It was somewhat limited; but we hope next year it will be more extended.

Black Hamburgs were very superior. The same class at Birmingham, Manchester, and Liverpool, cannot be compared to the few pens here exhibited—indeed they were pronounced by the Judge to be perfection. There are more of this breed kept in this neighbourhood than any other place we ever saw. They are first-rate layers, and also good birds for the table. Silver-spangled were very good, as also were Golden-pencilled. A pen of Silver-spangled was claimed for £3 3s., and one pen of Duckwing Bantams for the same amount.

Ducks were poor in consequence of the prize being small. There were only five entries.

Of Pigeons, the Carri rs, Almonds, and Barbs were very good. We are in a position to state that about twenty entries of Pigeons were returned, there being no room to accommodate them.

SPANISH (Black).—First, E. Browne, Sheffield. Second, E. Smith, Middleton.

DORKINGS (any variety).—Prize, E. Smith, Middleton.

COCHIN-CHINESE (any variety).—First, W. Wood, Sheffield. Second, E. Smith, Middleton.

GAME (any variety).—First, S. Brown, Macclesfield. Second, W. Foster, Butley.

HAMBURGS (Silver-pencilled).—First, M. Dawson, Middleton. Second, W. Wood, Sheffield.

HAMBURGS (Golden-pencilled).—First, J. Smith, Sutton. Second, J. Dawson, Middleton.

HAMBURGS (Golden-spangled).—First, N. Marlow, Denton. Second, W. Kitchen, Macclesfield.

HAMBURGS (Silver-spangled).—First, E. Smith, Middleton. Second, N. Marlow, Denton.

HAMBURGS (Black).—First, J. Thomas, Macclesfield. Second, W. Kitchen, Macclesfield. Highly Commended, S. Brown, Macclesfield.

GAME COCK (any variety).—Prize, H. Stanhope, Adlington.

DORKING COCK (any variety).—Prize, J. Hall, The Fence.

BANTAMS (any variety).—First, W. Silvester, Sheffield. Second, N. Marlow, Denton.

DUCKS (Aylesbury).—First, J. Hall, The Fence. Second, W. Forster, Butley.

DUCKS (any distinct breed).—Prize, T. Smith, Langley.

PIGEONS (any distinct breed).—First and Second, A. L. Silvester, Birmingham.

Highly Commended, S. Orme, Sutton. *Owls*.—First, F. Key, Beverley.

Second, J. Filding, Rochdale. *Amoud Tamblers*.—First, A. L. Silvester, Second, S. Orme, Sutton. Highly Commended, A. L. Silvester, *Porters*.

Prize, E. Browne, Sheffield. *Jacobins*.—First, H. Yearley, Birmingham.

Second, N. Hudson, Sutton. *Nans*.—First, J. B. Edge, Birmingham.

Second, H. Yearley, Birmingham. *Tantrails*.—First, T. Ellington, Beverley.

Second, J. B. Edge. Highly Commended, H. Yearley. *Tumblers* (any variety).—First, S. Orme. Second, H. Yearley. *Turks*.—First, S. Orme. Second, G. Grove, Liverpool. *Turbits*.—First, W. Whitson, Langley. Second, G. Greaves, Sutton. *Tipters*.—First, J. D. Edge. Second, E. A. Hargrave, Birmingham.

JUDGES AT THE BIRMINGHAM POULTRY SHOW.

FINDING by statements conveyed to me, both orally and by many letters, a mis-statement is now being purposely circulated respecting my not officiating at the last Birmingham Poultry Show, permit me simply to state that the particular appointment, as then proffered me, I could not with honour and straightforwardness accept; and, consequently, it was by myself altogether declined.

From that cause only my customary services as hitherto, in accordance with my own wishes, gratuitously rendered from the institution of the very first Birmingham Exhibition to the present year, were stated to be no longer required.—EDWARD HEWITT, *Sparkbrook, Birmingham*.

PRIZES FOR RABBITS.

ENTIRELY do we coincide with "QUIS" whose communication we published in our last Number. The prizes for Rabbits should be so offered and awarded as to encourage, primarily, the improvement of the breeds that are most useful and commercially valuable.

We have nothing to say against prizes being offered for superior length of ears, or beauty of markings, for such prizes encourage the cultivation of a taste for a home-amusement; and, besides, you cannot promote the breeding of any kind of Rabbit without in some degree promoting the breeding of all other kinds. Poultry exhibitors have had this general influence over all varieties of fowls, though at first the prizes were directed only to a few.

We would give the largest, and the most numerous prizes, to most-meat-producing Rabbits, and to the Rabbits the fur of which is most valuable. If these two good qualities could be united in one variety, then that variety should have the highest of the awards.

It is probable that many of our readers are not aware of the value of these too-much-neglected animals.

We know of one warren at Brandon, in Suffolk, whence we have been told twenty thousand Rabbits are sent annually to London. Hundreds of thousands are imported every year from Ostend and other places along the coasts of Holland and France. No less than one million and three hundred thousand are sold yearly in Lendehall and Newgate Markets; and if to these are added the numbers sent direct to the retailers, and those consumed in country districts, we shall not be far wrong in naming three millions as the probable number of Rabbits eaten in England annually.

Then as to the value of the skins of some of the varieties, there was a time, half a century ago, when a single skin of a Silver Grey Rabbit, Silver Sprig it was then called, was worth 3s.; these skins sold now for 30s. per dozen. They are chiefly exported to China, and a friend informs us that a very short time since he saw one heap, valued at £4000, about to be shipped to that country. The skins of Angoras, Chinchillas, and some others are equally valuable. The fur of even the commonest of Rabbits is valuable in a less degree for the manufacture of what are called beaver hats.

SOUTH OF IRELAND POULTRY, PIGEON, AND CAGE BIRD ASSOCIATION.

THIS, the second Show, was held on the 2nd and 3rd inst. in the Athenæum, Cork, and was decidedly superior to last year's both as to the number and quality of the specimens exhibited.

The classes of *Spanish* and *Crested Pheasants* were considered by Mr. Tegetmeier to be extremely good, and the *Dorkings* in particular very superior—quite above the average attained by the class at English shows. In this class a Silver Medal, given by Mr. Ussher, of Camphire, co. Waterford, for the best pen of Silver Greys, was carried off by J. C. Perry, Esq., from thirteen competitors.

In *Pigeons*, also, there was a manifest advance on last year. There were several pens of excellent Carriers, Pouters and Almond and other Short-faced Tumblers. The Fantails were numerous, and, as a class, quite above the average seen at exhibitions.

SPANISH.—First, R. P. Williams, Clontarf, Dublin. Second, F. Hodder, Templelawn, Cork. Highly Commended, J. C. Perry, Cork; R. W. Boyle, Dublin. Commended, A. E. Ussher, Cappoquin. *Chickens*.—First, Mrs. Dring, Glamire. Second, R. W. Boyle. Commended, F. Hodder.

DORKINGS.—First, F. Hodder, Cork. Second, R. W. Boyle, Dublin. Highly Commended, R. P. Williams, Dublin. Commended, J. C. Perry, Cork; Hon. Mrs. H. B. Bernard, Bandon. *Chickens*.—First, J. C. Perry, Cork. Second, A. E. Ussher, Cappoquin. Commended, F. E. Curry; T. O'Grady, Bandon; A. E. Ussher; R. W. Boyle; R. P. Williams.

GAME.—First, J. C. Perry, Cork. Second, J. Green, Cork. *Chickens*.—First and Second, T. Mayo, Upper Conynmore, Mallow. Commended, J. C. Perry, Browningstown.

POLANDS, Black, White Crests).—Prize, Miss E. de Courcy Drevar, Blackrock, Dublin. Highly Commended, Miss E. de Courcy Drevar. Commended, Miss E. de Courcy Drevar.

POLANDS (Gold).—Prize, R. P. Williams, Clontarf, Dublin. Commended, S. Wakefield, Barrackton, Cork.

COMMENTS (Silver).—Prize, R. W. Boyle, 25, College Green, Dublin. Highly Commended, R. P. Williams, Hollybrook, Clontarf, Dublin. Commended, S. Wakefield, Barrackton, Cork; W. B. Weatherman, Richmond, Blackrock, Cork.

HAMPERON (Gold, Rose comb).—Prize, Mrs. Dring, Rockroove, Glamire.

HAMPERON (Silver).—Prize, R. P. Williams, Hollybrook, Clontarf, Dublin. Commended, F. Hodder, Templelawn, Cork.

COCHIN-CHINAS (Ruff r. Yellow).—Prize, R. W. Boyle, 25, College Green, Dublin. Commended, J. Brasington, Sunday's Well, Cork.

COCHIN-CHINAS (Partridge).—Prize, J. C. Perry, Browningstown, Cork.

COCHIN-CHINAS (White).—Prize, F. Hodder, Templelawn, Ballintemple, Cork. Commended, J. C. Perry, Browningstown, Cork.

ERAMA FOOTRA.—Prize, W. B. Weatherman, Richmond, Blackrock, Cork. Highly Commended, Hon. Mrs. H. B. Bernard, Coolmaine, Bandon.

BANTAMS (Schericht).—Prize, W. Corbett, Castleconnell, Limerick.

BANTAMS (Feather-legged).—Prize, J. Donegan, Mountonette, Cork.

BANTAMS (Smooth Legs).—Prize, J. Wigney, Langford Place, Cork. Highly Commended, A. E. Ussher, Camphire, Cappoquin. Commended, F. Hodder, Ballintemple, Cork. *Japanese*.—Prize, J. O'Sullivan, Blackrock, Cork.

TOUCANS.—Prize, J. Bruce, Milltown Castle, Charleville (Norfolk). Commended, Hon. Mrs. H. B. Bernard, Coolmaine, Bandon (Norfolk). *Pouter*.—Prize, J. C. Perry, Browningstown, Cork.

GERSE.—Prize, R. P. Williams, Hollybrook, Dublin. Commended, R. W. Boyle, College Green, Dublin; T. O'Grady, Roughgrove, Bandon. *Goldwing*.—Prize, A. E. Ussher, Camphire, Cappoquin. Commended, J. Brasington, Sunday's Well, Cork (Hong Kong); A. E. Ussher, Camphire, Cappoquin (Ireland).

DUCKS (Aylesbury).—First, J. W. Dyas, Ballintemple, Cork. Second, P. Hefferan, Lismore.

DUCKS (Rouen).—First, R. P. Williams, Hollybrook, Dublin. Second, W. B. Weatherman, Richmond, Blackrock, Cork. Commended, V. Tomkins, Sunday's Well, Cork; P. Hefferan, Lismore.

PIGEONS.

CARRIERS (Black).—First, T. Hare, Bishop Street, Cork. Second, Dr. Harvey, St. Patrick's Place, Cork. Highly Commended, Dr. Harvey; T. Hare. Commended, Dr. Harvey; T. Davis, Castle Street, Cork.

CARRIERS (Dun).—First, Dr. Harvey, St. Patrick's Place, Cork. Second, J. Perrott, Hayfield, Cork. Highly Commended, Rev. J. O'Sullivan, Blackrock, Cork. Commended, T. Davis, Castle Street, Cork.

CARRIERS (Blue or other colour, except Black and Dun).—First, N. Daly, North Mall, Cork. Second, Dr. Harvey, St. Patrick's Place, Cork.

POUTERS (Black-pled).—First and Second, J. Perrott, Hayfield, Cork. Highly Commended, J. Perrott, Hayfield, Cork. Commended, W. B. Weatherman, Richmond, Blackrock, Cork.

POUTERS (Blue-pled).—First and Second, Dr. Harvey, St. Patrick's Place, Cork. Highly Commended, W. H. Baldwin, Rossville, Lismore. Commended, W. B. Weatherman, Richmond, Blackrock, Cork; Rev. J. O'Sullivan, Blackrock, Cork.

POUTERS (Red-pled).—First and Second, Dr. Harvey, St. Patrick's Place, Cork. Commended, J. Perrott, Hayfield, Cork.

POUTERS (White).—First, Dr. Harvey, St. Patrick's Place, Cork. Second, A. E. Ussher, Camphire, Cappoquin.

POUTERS (Any other colour than Black, Blue, Red, or White).—First, J. Perrott, Hayfield, Cork (Splash). Second, Dr. Harvey, St. Patrick's Place, Cork.

TUMBLERS (Almond).—First and Second, Dr. Harvey, St. Patrick's Place, Cork. Commended, J. Lloyd, Warren's Place, Cork.

KITES.—First and Second, Dr. Harvey, St. Patrick's Place, Cork.

EALHEADS OR BEARDS.—First, Dr. Harvey, St. Patrick's Place, Cork (Blue Beards). Second, J. Perrott, Hayfield, Cork (Beards). Highly Commended, Dr. Harvey; T. Davis, Castle Street, Cork.

MOTTLES (Short-faced or other colours).—First, T. Hare, Bishop Street, Cork. Second, Dr. Harvey, St. Patrick's Place, Cork (Black Mottles). Highly Commended, T. Hare Black.

TUMBLERS (Red or Yellow).—Prize, A. E. Ussher, Camphire, Cappoquin.

TUMBLERS (Any other colour).—Prize, N. Daly, North Mall, Cork. Highly Commended, Dr. Harvey, Cork (Rosewing). Commended, W. B. Weatherman, Richmond, Blackrock, Cork.

FANTAILS (White).—First, E. Nash, Lakelodge, Glamire, Cork. Second, T. O'Grady, Roughgrove, Bandon. Commended, W. Hare, Cork; J. Perrott, Hayfield, Cork; J. Pike, Rosborough, Cork.

FANTAILS (Black or other colour).—First, A. E. Ussher, Camphire, Cappoquin. Second, N. Daly, North Mall, Cork.

JACOBS (Any other colour).—First, F. Hodder, Templelawn, Cork (Motte). Second, T. Babington, jun., Monkstown, Cork (White).

BAMBS (any colour).—Prize, J. Perrott, Hayfield, Cork (Red). Highly Commended, T. Hare, Bishop Street, Cork.

OWLS (any colour).—Prize, N. Daly, North Mall, Cork (Blue). Commended, J. Perrott, Hayfield, Cork (Yellow).

TURBINS.—Prize, N. Daly, North Mall, Cork. Commended, T. O'Grady, Roughgrove, Bandon. Commended, J. Perrott, Hayfield, Cork.

NESS.—Prize, T. O'Grady, Roughgrove, Bandon.

MAGRITS.—Prize, P. Goulding, College Road, Cork (Black).

SONG BIRDS.

Yellow Canaries.—Prize, W. Corbett, Castleconnell, Limerick. *Green Canaries*.—Prize, W. O'Beet, Castleconnell, Limerick. *Molly Canaries*.—Prize, W. Corbett, Castleconnell, Limerick. *Goldfinch Males*.—Prize, J. Corcoran, Cork. Commended, F. Hodder, Templelawn, Ballintemple, Cork. *Linnets Males*.—Prize, Rev. J. O'Sullivan, Blackrock, Cork. *Thrushes*.—Prize, W. Waters, Monkstown. Highly Commended, J. Lloyd, Warren's Place, Cork. *Nightingales*.—Prize, Rev. J. O'Sullivan, Cork. *Sylphs*.—Prize, R. Daly, Wellington Square, Cork. *Bul Finches*.—Prize, F. Hodder, Templelawn, Ballintemple, Cork. (Speaks one sentence and several words). *Goldfinches*.—Prize, E. Creagh, Greenmount. Commended, P. Mahony, Tuckey's Veet, Cork. *Linnets*.—Commended, B. A. Hyde, Cork.

JUDGES.—Of Poultry, J. Blandford, Esq., Doolybeg, Cork; and W. B. Tegetmeier, Esq., Muswell Hill, London.

Of Pigeons, John Austin, Esq., Panorama Terrace, Cork; and W. B. Tegetmeier, Esq. **Of Cage Birds**, W. T. Jones, Esq., M.D., Cork; and Adam Parker, Esq., Landscape, Cork.

PERTH POULTRY SHOW.

MR. ANDERSON used to style himself the Wizard of the North. He may have been so far as legerdemain was concerned; but the real northern wizard was Sir Walter Scott. We have passed the age of romance, and have long since dealt more with the realities than fictions of life—novels among the number; but Scott was not, properly speaking a novelist, he gave history with a sauce piquante or poivrade; and when other authors of imaginative works are either unlearned for because the time or taste for them has past away, or forbidden because their tendencies are doubtful, Scott's works will be allowed in every library, and read by all readers: thus, the nearer we got to Perth the more we were engrossed with the recollections of the "Fair Maid" of that ilk; and many names and places were familiar. Thanks, then, to Sir Walter, we were at home in a strange place. Strange no longer, for it has inaugurated a regular poultry show.

We have hope we shall some day have a good supply of poultry from Scotland. We already receive a goodly quantity, but it is deficient in quality. From inquiry we made on the spot we find it returning a remunerating price; if it do so when woefully deficient in merit, what would it do if the quality were nearly perfect? We do not believe it would involve any greater outlay than at present, no more food would be consumed. Now, in order to insure size the fowls must be kept till they are full grown: this not only involves consumption for a long period, but it also implies an age at which a fowl is adult or nearly so, and, consequently, hard. This necessity arises from the want of size in the breed; one of a larger race would be large enough to kill, and much larger than the birds now brought to market when only half as old as they are. Now, if poultry be worth attending to at all, see the gain there is in the substitution of a good for an inferior breed; there is an economy of the food that would be eaten during two months or more, and the return for that which was eaten would be at least double in weight of food. The qualities would not bear comparison; there would also be a much readier sale for the improved quality.

All this has been felt by the nobility and gentry in those parts, and they have wisely determined to use their influence in favour of any improvement.

The plainest and probably the most effectual method was to set on foot and to support a good poultry show: hence that we have to record and to remark upon. The prize list was a very liberal one, and brought over some of the English exhibitors; we trust only an instalment of those we may expect another year when the Show is better known.

The first class was for Silver Grey Dorkings. This was, as it has been everywhere, a failure. Ten pens were entered, and as this colour is peculiarly admired and insisted upon in Scotland, we looked for perfection, but we found nothing of the kind. There were not three perfect pens in the class; there were only two cocks without white in their tails, and few with perfectly black breasts. Many of the pens here disqualified would have sold well in the open competition. We should like to see these classes abolished at all shows, and the amount of the prizes offered for them added to that which follows, and where all colours are admissible. There were very fine birds shown, and although the prizes went to England, Perthshire and the surrounding country were well represented. The Ladies Louisa Thynne and Julia Cornwallis, and Mr. Berwick are frequent winners at the English shows. Lords Kinnaird and Wemyss showed very excellent birds; the latter, more fortunate than the former, gained two prizes. Lord Binning showed good Dorkings. There were also two other classes—one for Silver Grey, the other for Dark Grey hens. Both filled well. They were remarkable for the number of the nobility who were competitors, and the quality of the birds shown.

The Spanish fowls were very good, and the principal prizes remained in the north. It is worthy of note that in this breed, where good qualities increase with age, the chickens have of late been better than the adults. Eleven pens were here deemed worthy of notice.

The Black-breasted and other Red Game showed well. The first prize went to Halifax, the other remained at home. It would seem to be necessary to tell our Scotch friends that in dubbing cocks, the whole of the comb should be removed close to the head. Many of the birds shown in this class had so much left, we could but think it was done purposely. The Duck-wings were good, but not numerous.

The Cochon-Chinois were also good, especially those belonging

to Messrs. Berwick and Watkin. Some of the pens shown would, nevertheless, seem to make it necessary to remind exhibitors that size is not the only requisite of this breed. The Whites were hardly of average merit.

We cannot speak too highly of the *Brahma Pootras*; they were in every respect excellent—in size, colour, and all the requisites of the breed.

In the Silver-pencilled *Hamburghs* the white deaf ear was entirely wanting: hence the first prize was withheld. The Silver-pangled were very meritorious, and Lady Julia Cornwallis took first prize. The Golden-pencilled and Spangled left nothing to desire; Mr. Entwistle's birds in the former class were of high merit.

There was a prize offered for old *Scotch Grey*, and a pen was shown of good useful fowls. We could not discover any marks of purity about them.

Polands were very weak, and two out of three prizes were withheld.

In the "variety" class, there was a pen of curious fowls. Both in cock and pullets, from the nostrils to the front of the skull, there was no comb, but a red skin. Where it reached the front it divided, and two very good spikes, perfectly round, stood up, rather inclining to the front.

All the *Bantams* were very good. Mr. Anderson and Lord Binning's *Southern* and Mr. Shorthose's *Game* deserve mention.

A peculiarity here was a good class of *Norfolk Turkeys*, the prizes were scattered about, and the successful pens weighed 57 lbs., 52 lbs., and 49 lbs. The class for Grey or Cambridge Turkeys did not fill.

White *Geese* showed well, and weighed 59 lbs., 51 lbs., and 45 lbs. The Greys did not distance them as they mostly do in weight, they weighed 59½ lbs., 58½ lbs., and 47 lbs.

There was a very good class of *Aylesbury Ducks*, and they weighed well, bringing 22 lbs., 20 lbs., and 18 lbs. Rouen Ducks have increased everywhere in weight, and Perth was no exception; as their colours were perfect it was necessary to weigh them. They surpassed the *Aylesbury*, weighing 22 lbs., 20 lbs., and 19 lbs.

Next came the classes for *Single Cocks*. Three Silver Cups, value five guineas each, were offered for the best Dorking, Spanish, and Game cocks; it was a very hard contest in each class. Lady L. Thynne won that offered for the Dorking; but even her celebrated bird was hard run by Lord Binning, Lady Julia Cornwallis, and the Rev. J. G. A. Baker. Master Kedpath, of Edinburgh, won the Spanish, but had great difficulty in defeating Mrs. White, who showed three birds of unusual merit. Mr. Adams, of Beverley, won the Game cup, beating fourteen competitors.

The *Pigeon* show was good and very attractive, and 107 *Carnaries* shown in good handsome cages were very pleasing.

The Show was held in the City Hall, a building admirably adapted for the purpose, large, lofty, entirely lighted from the roof, and quite free from draught. The poultry filled it with 255 pens, on the top of the poultry stood the Pigeons, and all one end of the room was devoted to *Carnaries*. They filled it. We are happy to say the Show will be annual, and we hope it will be supported by English amateurs.

Mr. Brown was an able, obliging, and indefatigable Secretary. Mr. Baily, of London, was the Judge.

HOW AM I TO PROTECT MY HIVES?

HAVING got up a stock of some half a dozen hives of bees, the study and interest I take in which, have afforded me a great deal of amusement and gratification. They are all well domiciled, and have every convenience for supering and observation, and, to my view, complete, save suitable covers for protection. I would, therefore, confidently appeal to the many apian readers of your Journal for their fraternal assistance.

I have already ransacked your list three or four volumes without meeting anything to suit my want. Read attentively the pan-and-hackle controversy. I would sooner stick to my temporary tick-knives of cuba matting for a covering than adopt the former bare, unsatisfactory affair. The latter may very possibly possess all the advantages its advocate stated, and still be unsuitable in my case, as I must have them always more readily injected than the trouble and litter that would inevitably ensue in continually moving off and on the hackle, at the same time quite soiling their neat surroundings.

Why not build a house? some one may say; but my pre-

judges are all against such, thinking from the results of my own observation that bees thrive much better placed on single pedestals.

My boards are principally square, larger by an inch all round than the hives. How would it do to remove the upper half of that inch—say to half the thickness of the board, the under part to be left to support an outer moveable case formed of inch wood? Would such a case not be too close and hot? Having the garden wall in their rear might the back of such not be omitted? What form of a roof would be most useful and graceful, and how would I take away from the stiff, plain appearance the front of a square wooden cover would have?—W. J.

[The accompanying woodcuts represent the two descriptions of hive-covers in actual use in our own apiary.

FIG. 1.

The back and front of *fig. 1* are formed of half-inch wood 15 inches high in the centre, nailed to sides of three-quarter-inch wood 11 inches high. It rests on the floor-board, and is retained in its place by a fillet at the bottom of half-inch wood 2 inches wide, which fits loosely outside the floor-board. The roof consists of two large slates (Inches) 24 inches by 12 inches laid on the top, and removable at pleasure. It possesses the merits of cheapness and efficiency.

FIG. 2.

Fig. 2 is made of half-inch wood 11 inches wide, dovetailed together, and fastened by means of glue and a brad driven through each of the tenons. It rests on the floor-board where it is retained in the same manner as *fig. 1*. The roof is separate, and is formed of half-inch wood 11 inches wide, cross-bradded together with a central-turned acorn 24 inches in diameter. Its frame fits loosely over the hive-cover, and rests on angle pieces at the corners. A half-inch opening which cannot be seen in the engraving is left under the eaves all round for ventilation. If more ornament be required panels may be shown at the front, back, and sides, formed of some neat moulding.

Our floor-boards (like your own) project an inch all round the hives, and this allows nearly three-quarters of an inch space between the latter and the outer cases. If desired, this space may be filled with some nonconducting substance. An ex-

perienced apiarian friend always dries the fine and short grass cut from his lawn, and applies it to this purpose, but we have never found it necessary to do so.]

EXAMINING BEES WITHOUT BEING STUNG.

THE impunity with which your experienced correspondents appear to meddle with the bees and investigate the interior of the hives, puzzles me exceedingly. I should not suppose my bees are more savage than other people's, but when I have disturbed them by taking out a bar or otherwise, I have only raised a wild storm of little warriors, and although covering myself with net as carefully as I could, generally get stung somewhere. I have also found great difficulty in restoring the bar to its place without crushing some of the bees. A queen I have never seen, but should much like to make myself acquainted with her majesty and subjects "at home," without injury to them or from them. Can you give me any instructions in this matter?—J. H., *Malden*.

[A little smoke from some vegetable substance (fungus, rags, touchwood, or tobacco, will either of them serve the purpose) blown into the hive under the crown-board about half a minute before removing the latter, will generally subdue the pugnacity of which you complain. We can give no better instructions for these manipulations than are to be found in page 167 of the twenty-sixth volume of THE COTTAGE GARDENER. By adopting frame-hives instead of plain bars you may obviate the risk of crushing bees when removing the combs from, or returning them to their places. We understand that "A DEVONSHIRE BEE-KEEPER" has invented what he calls "a compound bar-frame," by means of which bar-hives and frame-hives may be used promiscuously in the same apiary without forfeiting the advantages arising from the power of inter-hanging combs in every hive, and hope ere long to be enabled to give a full description of this contrivance.]

HONEY AND CHEMISTRY—INTRODUCING FOOD DIRECTLY INTO THE COMBS.

THE passage to which "A. B." refers in page 267 occurs in THE JOURNAL OF HORTICULTURE of the 26th of November, and is as follows:—"I believe that even pure honey will not keep unless placed in the combs by the bees themselves, and I am very sure that all artificial compounds require to undergo a chemical change in the stomach of the bee before they can be stored in the combs in such a state as to keep good throughout the winter."

By this I meant to point out the mechanical difficulty of placing honey in the combs without the occurrence of air-bubbles and impurities, which could, probably, only be avoided by accepting the agencies of the bees themselves. Although I did not then intend to raise the question as to whether honey does or does not undergo a change in the stomach of the bee, I can have no objection to state my opinion that such a change does really occur. On inquiry, I find that this is regarded as an established fact by the scientific world, although I have not been able for the present to ascertain upon what authority it rests.

With regard to the chemical change which all artificial food undergoes in the stomach of the bee, I know not how to advance more conclusive proofs than have been furnished by my own observation. Not only is the flavour of the compound modified in a very appreciable degree, but the tendency to crystallisation is either altogether all lost, or very greatly diminished. Any one who has been in the habit of administering to bees large quantities of artificial food can scarcely fail of being able to confirm my observations in this respect.

Some dozen years ago, not having then had quite ten years' experience in bee-keeping, I was much taken up with the plan of introducing food directly into the combs, and finding difficulty in perfectly filling all the cells, I set to work and made a small wooden tank 1½ inch wide by 9 inches deep and 11½ inches long, which just admitted a single comb. I fancied that by placing an empty comb in this receptacle, and then slowly filling it with food it would expel the air from every cell as it rose, and thus save me much trouble in pouring food into the combs. Alas! the first trial dispelled the illusion. After slowly filling it with liquid food until the comb was entirely submerged, I had

the mortification of finding that the cells remained completely empty! Nothing daunted by this failure, I returned to my former mode of filling combs, until at length I supplied a weak swarm with such an overpowering quantity that the bees declined to meddle with it, and allowed it to remain where I had placed it. The result was most disastrous. A thick coating of mildew gathered on the exposed surface of the syrup and entirely enveloped the combs so that utter ruin was the consequence. It was the recollection of this deplorable failure which induced me to caution your apiarian readers against over-estimating the advantages of introducing artificial food by pouring it into the combs.—A DEVONSHIRE BEE-KEEPER.

DRIVING BEES.

I CAN fully endorse all that is stated in page 287, by "B. & W." in favour of driving. The attainment of this most necessary apiarian accomplishment is often a sad stumbling-block in the path of the young bee-keeper. Any one who will trouble himself to refer to page 52 of the twenty-first volume of THE COTTAGE GARDENER, may there find chronicled the difficulties I encountered before I could succeed in driving a hive of bees. At the present time I think but little of it, and seldom find it necessary to don either a bee-dress or gloves for the occasion. Any novice in apiarian matters will find it easy to acquire the same facility if he can get an experienced friend to give him a few lessons in the art.—A DEVONSHIRE BEE-KEEPER.

UNITING BEES IN TWO BAR-HIVES.

WOULD "B. & W." be kind enough to give his plan of making a union with two bar-hives, as he mentions at page 247? For my own case I have never removed the top-board.—STEWARTON APIARIAN.

[There must be something quite peculiar in the Stewarton system of bee-box management, if, as I understand from the query of the "STEWARTON APIARIAN," he and others in the north do not remove the top-board, and yet contrive, when effecting unions of stocks, to get the bees to ascend instead of descending. In my own case I have always given the bees in each hive access to each other by opening a one-inch or two-inch hole in the top of the lower hive, down which they have invariably gone after a greater or less period of time. All bees will in fine weather find their way into the open air sooner or later. As my entrances are all in the lower hives, every bee when going out must descend and pass through the lower hive, where on returning it remains as a rule.]

If a "STEWARTON APIARIAN" has my little work, "The English Bee-keeper,"* to refer to he will find illustrations of the sort of bar-hives and boxes which I have always made use of, as well as a fuller answer to his question than I can give here.—B. & W.]

VENTILATING HIVES DURING THE WINTER

THREE winters ago I purchased a hive (wooden box) of bees from an apiarian, who was selling his stock pending his removal to a distant part of the country. On going to see the bees prior to purchasing I found all his boxes, eight in number, thoroughly ventilated, the doorway being left open to its full width, and a four-inch-square opening in each crown-board, only covered by a piece of perforated zinc; the hives were in a small wooden bee-house open to the front. This starvation state of affairs of course elicited from me a few questions as to the cause of such apparent carelessness for his bees, when I was informed that such had been his practice for a number of years. Some years ago he had been in the habit of keeping his bees free from ventilation during the winter; but not infrequently he had the mortification of losing his bees. As a last resource he seems to have adopted a directly opposite plan, by ventilating them in a manner above described, and, singularly enough, he never afterwards lost a hive.

Without, then, seeing the reasons for this success, the facts were too plain to admit of doubt: I therefore adopted his plan, and up to the present have been favoured with similar success. Many bee-keepers of the old style of skep without opening at the

top (and there are a goodly array of them in this neighbourhood), have seen my hives, and their greatest cause of wonder seems to be that the bees are not perished. My experience so far indicates that bees kept in a comparatively dry atmosphere by thorough ventilation will come through the most severe winter in our climate in a better condition than when ventilation is prevented.

I may here say I think it advisable to ventilate early in October, but not continue it longer than the middle of January or the commencement of February, although I have ventilated until the middle of March; and after this the hive so ventilated, without being fed, has sent out its first swarm only second in the neighbourhood, the first being thrown off only a day or two earlier from a stock which had been fed during the whole of the spring.

There is also another point worthy of notice—namely, when ventilated they require a considerably less quantity of food. As an illustration of this—I, and a friend near, at the beginning of last winter had each a hive very similarly situated in most respects, except that mine had only 12 lbs. of honey as their winter stock, while his had upwards of 20 lbs. I ventilated mine in the manner before described; whilst my friend, I suppose out of kind consideration for his favourites, added a bell-glass over the perforated zinc by way of making comb-side a little more congenial. Before our bees were able to provide for themselves a fresh supply, in the following spring my friend's stock was bankrupt, he having to eke out their supply by feeding, while mine paid more than twenty shillings in the pound, and sent out a prime swarm three days earlier than his.

Numerous instances have come under my own observation during the last two winters of hives perishing (in one case seven) through the severity of the frost, while the hives through want of ventilation have been saturated with moisture.

To-day (January 1st), I have been cleaning the foot-boards of my hives, and although they are ventilated to such an extent, I find evident indications that breeding has commenced in one. The hive is not a bar-and-frame one, so that I cannot verify my suspicions by looking for the eggs; but while some bees are hanging ladder-form, others are busily engaged in the cells.

I have been led to make the above remarks in the hope that "A DEVONSHIRE BEE-KEEPER" will oblige us by giving his experience in favour of non-ventilation, which I see he recommends in your Journal of Oct. 8 to your correspondent, "A. W.," and also because I think there may be many who have lost their bees through not ventilating, who will be glad to hear that the opposite plan has, in several instances extending over a number of years, been proved to be (if I think I may say) an improvement on his recommendations.—W. JOHNSON.

VARIETIES.

COLONIAL CABINET WOOD.—A novel and beautiful specimen of ornamental wood grown in this colony has recently come under our notice. But a small quantity, it is understood, has yet been wrought, indeed the first specimen was only recently exhibited in cabinet articles by Mr. Charles Hunt, of Jamison Street. At his establishment a chert table has been manufactured from this handsome and strongly-marked wood, which cannot fail to attract attention in the midst of other varieties of colonial and European cabinet timber. There is a decided contrast in the colours. The heart-wood is a pale yellow, unvarnished; and the sapwood a dark sienna, with a fine serpentine grain at intervals (not very frequent), broken by knots. It is said to be an excellent material for cabinet articles, as it is fine in grain, crisp, yet firm, when cut in veneers, and taking a fine polish. The strong y-marked features of this wood distinguish it clearly from Walnut, its characteristics being much bolder; but its quality would fit it for many of the ornamental works in which Walnut wood is used. There is some doubt as to the species of this timber, some ascribing it to the Pine family, others calling it Casuarina, some Sweetoak, and again Album. Mr. W. Tuckey, a practical cabinetmaker, is understood to have first brought the wood into notice, and intends, we believe, to visit Europe with the view of presenting specimens at the International Exhibition of 1862. It appears to be a very valuable acquisition to the cabinetmaker, and probably will add to our export of fancy woods. The tree is said to be plentiful in the extreme southern districts of the colony, growing to the height of 60 feet or 70 feet, with a barrel averaging between 18 inches and 2 feet in diameter.—(Sydney Morning Herald.)

* To be had, price 2s., of Messrs. Dean, London.

METEOROLOGY OF THE WEEK.—At Chislewick, from observations during the last thirty-five years, the average highest and lowest temperatures of these days are 42.5° and 30.5° respectively. The greatest heat, 69°, occurred on the 19th in 1838; and the lowest cold, —4°, on the 19th in 1848. During the period 135 days were fine, and on 103 rain fell.

PROGRESS OF CROSS-BREEDING AMONG FLORISTS' FLOWERS.

ANY new plant which the cross-breeder brings into the world, and which was never in the world before, may be called, figuratively, a new creation. And if you ask him how he knows that his new plant has not been in the world previously—at least, not since the flood—he will give you as the reason, that the remains of the old world have not yet brought to light any fossil kind or kinds of plants which could by their union produce such a form as his new seedling. That,

then, forms the text for disputes, without end, about the origin of species, and the races of plants, the extinct vegetation before the flood, the ways of clothing the earth after the flood with forms of vegetation differing from the extinct races, and differently disposed as to countries and climates.

Call the seedlings what they will, I shall never call in question aught on the subject which cannot be proved or disproved by direct experiment. One fair experiment is worth all that the whole weight of the opinions in Europe could place in the scale against it; and as to wrangling about things which cannot be proved by direct experiment, it is not of the slightest use that I can see.

My limited experience has proved beyond the possibility of a doubt, that soil, or the different kinds of soil, have a mighty influence on the variegation of seedlings. Some of the discussions on the subject last summer supposed a chemical origin rather than a diseased constitution to such variegation in plants. Punch being the healthiest and the best-known kind to me of all the Geraniums, as far as its genealogy went, I took to it once again to see if it would turn out seedlings as it has done in former years on my present soil. Punch is only at home on the chalk formation. Give it a chalky soil on a chalk bottom, and cross it by what you please from the variegated section, the seedlings will all come quite green, and no variegation in any one of them. I often said how true to kind so many of the seedlings of Punch, by its own pollen, would come.

Well, last summer, as a last resource, I crossed many flowers of Punch with the healthiest of my stock of seedlings, meaning those most free from variegation, and out of two hundred seedlings from that cross now before my window, nineteen out of every twenty of them are blotched and speckled as if they would be all variegated. What, then, can, or could induce this tendency to variegation, unless it be the difference of soil? By its own pollen all seedlings of Punch in this garden come without a speck of white, but they vary from the parent very much, and not one in fifty of them is like it; whereas on the chalk Punch is all but a botanical

species, reproducing itself at the rate of from 70 to 80 per cent.

You are not, therefore, to suppose that you can obtain the same results from crossing a flower of which you read in books, by merely doing what some one else did before you. But it is of much consequence to save you time and trouble to know what has been done by crossing before your day: hence the reason for this rapid sketch of the biography of crossed plants, which you now can see is to be written, without favouring this or that opinion, or anything else which cannot be proved by pollen.

Then, in the order of time, the Rhododendron was the next subject for hybridising; and it was soon discovered that the genera Azalea and Rhodora could not be held apart from Rhododendron, as they were capable of intermixing.

The Pelargoniums were as early, if not earlier, crossed than the Rhododendron; and there was this marked difference in the seedlings of the two great families—those of the Pelargonium were, most of them, barren plants, or mules as they were called, after a turn or two at crossing them; whereas those from the various sections of Rhododendrons were all but fertile to the end of many generations. It was from that disposition in the Pelargonium that the first idea of mules took its rise, and found favour with those who handled them.

In the Crinum and other sections of the great Anaryliid order were also found some barren seedlings from crossing, but not nearly to the same extent as in Pelargonium, and the inference which obtained in respect of them was, that the cause of barrenness was owing to the difference of the constitution of the two parents, and not from the dissimilarity in their looks, or their genealogy. That inference has not yet been proved either way by experiments, and is a subject well worthy the care and attention of cross-breeders, or, I should rather say, hybridisers, for it is only by the union of distinct wild kinds that the doctrine could be proved to be right or wrong.

Then, to understand how a difference of constitution in any two species of plants exists, you have only to suppose one of them to be a marsh or water plant, and the other to be the inhabitant of some dry region. Or, to come nearer home, take any of the recent Sikkim Rhododendrons which Dr. Hooker discovered growing like Mistletoes in a dropping climate, and cross it with some dry alpine Rhododendron or Azalea, and if there is any truth in the doctrine of constitutional discrepancies, the seedlings from that union should exhibit a large percentage of barren plants, or mules, if you like it better.

All that is practically known about the pollen influence of Camellias is this, that one often finds a stray anther and stamen in the most double flower, and that that pollen is better, or will give a better result than that from a half-double flower. But, as in all other cases of breeding in-and-in, I suspect the influence of good cultivation goes farther than that of the pollen in every instance, although some of our best florists believe their

"hybridising" is the main element of success; thus confounding two things which are essentially quite different. The province of the florist being the improvement of races, that of the hybridiser the formation of new races to be afterwards improved.

Linnaria, Pentstemon, and Calceolaria were the next genera that were crossed. But *Verbena melandris*, the first of the sacred race, was introduced five years before the elders of the Calceolarias, *Verbena Tweediana* and *teucrioides* soon followed; but we never had any distinct hybrid *Verbenas* from their union, or at least not more dissimilar than seedlings which may be had now from one pod. Cultivation and not the pollen has certainly been the making of all our present race of *Verbenas*. There are many things more simple than crossing *Verbenas*, and I believe few people attempt it in these days. The breeding in-and-in gives us as many mules now in *Verbenas*; and *Verbenas* not cross-bred at all, will give more mules from one truss than ever the *Pelargonium* had given, on which the doctrine of muling was founded.

The old *Pentstemon pulchellum* was the first of them that were crossed, and a still older one and a very dissimilar kind, called *angustifolium* was the one by which *pulchellum* took. The seedlings were very fertile.

Calceolaria made an uncommon sensation at first among all the crossers, from the fact that a stemless herbaceous kind whose leaves even died down in the winter, could cross or be crossed by a shrubby kind, or one with a woody stem. I recollect very well that the doctrine of botanical diversity did not then hold up the hypotheses of muling from such a cause. No seedlings could be more fertile in repeated generations than those which were obtained from such very dissimilar parents. But the doctrine of constitutional conformity was never more near to the truth than in that race. All the original *Calceolarias*, with all their disparity of looks, had but one uniform constitutional tendency, preferring a moist cold climate, and a degree of shade from the direct rays of the sun which we did not anticipate from what we then knew of the climate of the land of their birth. But it had been a problem to this very season among crossers, whence the self-planned flowers of a whole race of plants took to sporting into spinn flowers from the very first. The Messrs. Veitch solved that problem last summer, by introducing a sweet-scented *Calceolaria* of the arachnoidea section with spotted flowers direct from the locality of the former race. The probability is, therefore, that our supposed species in 1830, 1831, and 1832, were more seminal varieties in a wild state. At all events the new spotted flower might well be the father of a section of our seedlings in 1832-3.

No two plants could be more dissimilar in their appearance to a gardener or to a botanist than *Cereus*, or *Cactus speciosissimus*, and the whipcord *Cactus flagelliformis*, or both of them from the flat-stemmed kinds; but from their union I never yet detected a single barren seedling. Like the *Calceolaria*, their nature or constitution was exactly alike, and as opposite to *Calceolaria* as night and day. Yet they went to uphold the doctrine that similarity of constitution will overrule all other tendencies in its effects on cross-seedlings, and that all such will be fertile or very nearly so, not one in five hundred of the seedlings being otherwise.

In 1831 *Linningia* broke down botanically by the union of *Gloxinia speciosa* with the pollen of *Linningia guttata*, producing the true hybrid *Gloxinia glaucescens*, the first of that race now so gay and so very numerous. *Glaucescens* was thus the head of a new section of *Gloxinia*, by a hybridiser not far off, and the cross-breeders brought it by crossing in-and-in to what it is, and, as often happens, the new race sported into a newer one, the upright *Eiffiana*, which upright race is now the more favourite of the two. Speaking as a gardener, I do not see a single point in the generic character given of *Achimenes*, *Gesneras*, and all the cras into which continental writers have attempted to raise the various sections of them into the importance of genera proper—I say I do not see that any of these distinctions put together can uphold them from being one genus for all the purposes of the hybridiser; and when they are united again by his art there will be many new sections to improve; and every one of them, if I am not much mistaken, will uphold the doctrine of fertility in cross seedlings, owing to the constitutional similarity of the parent kinds. No family ever agreed more in their nature than does that long section of the family of *Gesnerads*.

As early as the period I am on now—that immediately suc-

ceeding 1830, a small white Gourd from Mexico, named *Cucumis osmocarpus*, with an egg-shaped fruit, was fertilised by the pollen of a cultivated Melon. The seedling produced a red fruit twice the natural size. The crossing of Melons with wild *Cucurbits* has been lately authenticated by M. Naudin, of Paris; and the Royal Horticultural Society have agreed, or their Council have agreed for them, that there shall be a competition next October at South Kensington for all sorts and sizes of Gourds, Pocket Melons, Snakes, Squash, and Pumpkins. That indeed was a very good move and a wise resolve. The next turn will be to select parents from these exhibitions for a new fancy set of such "fruit," to vie with illustrated-leaved *Egonias*, and to hang down from the rafters of the orchard-house until the day before the Show. Thirty years seem now a short period in the history of new races of plants, and in softening down of prejudices and presumptions arrived at from insufficient materials to prove a better, or at least a more practical result.

The coloured *Petunias* came in after the white at that period—1830. *Petunia phœnicea* was the first of them, and bloomed first in Ireland that year; and in 1831 it was first seen in bloom on the west side of Manchester, at Lower Broughton in a stove—I saw it there then. Well, what was the difference between *Petunia*, *Nierembergia*, *Salpiglossis*, and *Nicotiana*? or is there much difference between them yet?—such, I mean, as should be a bar to their union. But you ought to have lived at that period to know which was which, and which was the likeliest thing that should happen but did not yet come to pass. A good deal of dog Latin was wasted in the different views of that relationship; but the *Fuchsias* coming in directly afterwards, or perhaps before the heated blood in that contest had time to flow and return as does the hot-water system, the thing was soon lost sight of, save in the instance of the pure and unadulterated *Petunia*, of which we know not the end just yet.

But the *Fuchsias* were surely in before the time stated, and so they were; but what were they? They were neither parasols nor parachutes, it is true; but, such as they were, some say we have not yet seen their betters. But biography is barred from predictions, or should be, and I say nought about it; but it was full 1836 before ever a cross *Fuchsia* was in the market. I offered one that summer to Mr. John Henderson, then of the Pine Apple Nursery, and he told me there were several curious ones coming out the following year. Fulgens came by Hungerford Market in a dried state from Mexico that summer; and Mr. Standish made his first fortune out of the next on the list of introduced *Fuchsias*. From *Gracilis* and to *Virgata* of that day—to say nothing of *Coccinea* the mother of the family—to *Minnie Banks* and to *Comet*, which were shown to us of the Floral Committee last autumn twelvemonths, and to Mr. Smith's Mammoth double *Fuchsia* sent to us since then—I say, Look from *Gracilis* and *Virgata* to *Minnie Banks* and *Comet*, and from *Coccinea* to *Smith's Mammoth*, and say or see how much or how little we owe to the florists. D. BEATON.

A FEW DAYS IN IRELAND.—No. 10.

LOUGH CREW.

(Continued from page 301.)

WESTWARD about a quarter of a mile from the gardens either by road or pleasant walk, we reach the plain unpretending English church, from which fine views are obtained of Balsassiney and the tops of the hills of Míath and Westmeath, and Longford in the distance. The beautiful valley here it expands into a wide unshaded plain, dotted thickly with trees, and more woods in the far background. The foreground is lightened up with something more cheering and life-like than even hill-sides of trees in all their grandeur, in the shape of diversified well-cultivated fields, and great numbers of substantial stone two-storied cottages, speaking of comfort within, which at a distance appear singly, in groups, or in rows, but which are all built in pairs, and fenced in from the roadway with low stone-and-mortar walls, the front garden being intended to be ornamental. Each pair, therefore, has its offices and allotments distinct to itself. "The cottages are built of stone with dressed quoins, lintels, sills, &c. The ground floor consists of a kitchen, small store-room and bed-chamber. The floor is done with bricks set on edge. The upstairs floor consists of a large and smaller bedroom. The outside offices for the pair are placed under one roof, in the middle from the back of the house, so that each

tenant has his own entirely to himself, and consists of small dairy, cow-house with loft above, piggery with hen-house above, privy, ash-pit, &c. These are built with brick made on the estate. The cost altogether of such a pair of cottages is about £120. For such a house the garden or allotment behind is generally about one-eighth of an acre. There are many other pairs of cottages of a larger size, with three good apartments below and three above, and corresponding out-buildings. We learned that according to size the rents ranged from 30s. to 60s. per annum. If larger and with more land attached the rent, of course, would be higher. With even from one-half to one rood of ground, there is no difficulty in keeping a cow, such a help to a family, as so much grass land is easily obtained by the year as will keep the cow in grass in summer and forage in winter.

We were rather pleased to find such an experienced practical man as Mr. Stewart holding, as the result of long observation, ideas similar to ourselves as to the size of garden allotments. The small-bit-ground system has been the bane of Ireland—just enough to be able to live on in good years, and to starve on in bad seasons, land which the holder had no means of improving if he would, and which he feared to do if he could. The nightmare vision of a rise in rent in consequence being ever before his eyes. For a labourer constantly employed and receiving weekly wages, Mr. Stewart considers one-eighth of an acre about as much as he can properly manage in his own time. Many labourers on the estate now know the advantage of living in such a comfortable cottage with such a straight-lined allotment, and receiving regular wages, instead of occupying some crooked piece of ground, part ditch and half bog, and part poor soil, which he could not manage to improve if he would without getting into trouble with his next neighbour.

When good folks in England talk of the landlords in Ireland not doing this and that to improve their tenantry, &c., they should just ask themselves what they themselves could do, if, whatever their heart and intellect might dictate, they found their hands tied behind them in the shape of numberless of the most strange and complicated leases, which neither they nor their children could hope to break through. Mr. Naper has always been an improving landlord, and that part of his estate under his own control would have been an example and a pattern to others; ably seconded as he has been then and now by his agent, C. W. Hamilton, Esq., of Hamwood, and his land-steward, Mr. Stewart; but even he, however assisted, could not have done what has been effected but for the great crisis and social results of the famine years. The distress was then so great that all parties were drawn closer to each other under a great common misfortune. Bonds of consecrated feeling were then riveted that nothing but death could dissolve. The salt tears streamed down a veteran's cheeks as he told how, other resources failing, the deer park was next to cleared of its denizens to support human life. No pressure whatever was exercised on cottiers and small farmers unable to pay any rent; but those who wished to emigrate had not only the passage money paid, but a sum given to each that they might not be without means when they landed on a foreign shore. Others who preferred remaining at home, and who could neither pay nor do anything with their crooked, bog-spotted, pool-dotted, bit-and-bit patches of land, had them taken off their hands on the most honourable terms, and as soon as could be were located in cottages and allotments as workers on the estate.

Thus from the great calamity good has ultimately followed. These nice cottages and regular allotments are just so many types of what has been done for large farms of from 100 to 300 acres. We cannot go into details, for if able to do so they would be more suited to the columns of a purely agricultural journal. But just fancy if you can, a good breadth of land held by a number of occupiers, their holdings divided by wide open ditches in which the water stood rather than ran, and wide breadths of so-called hedges, in which the gaps occupied no inferior share, good for nothing but harbouring vermin, and occupying good soil with weeds enough to stock the holding, and large pieces of bog and swamp left in their natural loneliness, and the roads in such a condition that the patches of Potatoes or Oats could only be approached in fine weather. Then reverse the picture, and see the hedge-rows levelled and the ditches filled up, the land divided into large regular fields, with divisions of narrow trimmed hedges and ditches, good roads made as an indispensable, a deep outlet obtained for the superabundant water, and the whole ground drained by an experienced drainer (Mr. Miller), 4 feet being the regular depth for the feeding-drains; and the bottom

of these filled with a foot of stones obtained on the land. Notice that the bog, at first too soft to bear the weight of horses and plough, is cultivated with the spade until it is compressed and dry enough to bear any weight, and after being dressed with lime is turned with the rest into a beneficial rotation of cropping, instead of the never-ending series of Potatoes and Oats, and Oats and Potatoes, with which it used to be treated, and then observe how these enlarged farms with suitable buildings are eagerly sought after by men of capital, who are willing to pay such an enhanced rent as to afford good interest for the money sunk in improvements, and then you may form some idea not only of the extent but the practical utility, and the ultimately remunerative character of the land improvements at Lough Crew.

Eastward from the garden as already intimated, is the home farm, the buildings not so regular as in the newer farms, but large and commodious with room for housing and sheltering a great many cattle. On the improved breeds of sheep, ditto of pigs, the older ones well known at shows and more like donkeys than pigs, and the long genealogies of bulls and cows, we will not enter. The house of Mr. Stewart on the yard side is unpretending but commodious, and on the lawn side very showy in the pointed Gothic style, with a fine field of Mangold instead of a flower garden in front. The dairy is large and roomy as it would need be, heated by hot water when necessary, the churn being moved by a horse and machinery outside. All the carts, ploughs, machinery—as mowers, hay turners, and utensils were clean and dry, and protected from the weather when not in use. A new steam engine was just put up to thrash, cut, bruise, saw wood, &c., the latter preventing it being a sinecure on such an estate. The hay (hay they call it), was, as far as we recollect, built on stands that none should get musty near the ground, and all sorts of corn were thus built, the floor being made of stout pieces of wood laid across low cast-iron columns, with broad rounded tops, so that neither mouse nor rat could pass them into the stack. The only chance would be getting up concealed in a sheaf. A stack for want of a frame ready was built on the ground the other year, and we were assured the loss sustained by vermin would have paid for the stand, and then when put up it would last many years.

The fineness of the green crops, Turnips, &c., and crops in general, and the neatness and regularity of the hedge-fences, would almost at present enable a stranger to mark out the boundaries of the estate. This distinction, however, will not last long, and the sooner it is removed, the better as, to their honour be it said, many more gentlemen are doing everything they can to improve their estates. There are some 2000 acres at present in Mr. Naper's own hands, including the home demesne with its fine plantations and ornamental grounds. The whole of the grass land included in the park ranks as so much of the farm, from which not improvement and pleasure alone, but we believe profit is expected. A land-steward must have no sinecure who can thus superintend all this, and the general improvements on the estate. Mere philanthropy is a fine thing however directed; but it is best of all when the question "Does it pay?" can be answered satisfactorily. The true test of agricultural improvement is the finding that it secures an advantage to the landlord, as well as a more present advantage to the farmer and the labourer. We forget to say that we believe any of the farmers, with leases, may have their farms drained by paying a rise of five per cent. on the outlay.

With all this material improvement, what of the great field of mind, as influenced by education? We are convinced that when knowledge is appreciated, parents will make any sacrifice to procure it for their children, and that it is most valued when paid for. It requires a certain amount of intelligence, however, to appreciate knowledge, and when truly valued it is difficult to obtain in many country districts. Gentlemen may do much by opening up facilities in their own neighbourhoods. Mr. Naper has provided these facilities by building and supporting a nice school for the children of the district. We forget as to the schoolmaster, but we believe there are two female teachers. Though, properly speaking, Mr. Naper's own school, he has placed it under the supervision of the National Board of Education. There are about one hundred children generally present, the boys being taught reading, writing, and arithmetic, and in addition to these the girls are taught sewing, &c. Mr. Naper and the ladies take great interest in the working of the school and the progress of the scholars, give prizes for good conduct, cleanliness, and regular attendance, and a fine treat of tea, &c., on the terraces at the house in summer.

The neighbourhood is peculiarly favoured in the matter of education. We regret now we did not see the town of Old Castle, represented to us since as the openest and cleanest little town in Ireland. It belongs to Mr. Naper, and expects to do great things when the railway reaches it. Mr. Naper of late years has built forty nice slated cottages of six rooms each, with suitable out-offices, for labourers and artisans; and Mr. Gibson, an old townsman, left £25,000 for the purpose of educating and clothing the poor of his native parish.

These schools, by a plan laid down by the Count of Chancery, are managed by five trustees, three laymen, the Chief Secretary for Ireland, J. L. W. Naper, Esq., A. S. Dease, Esq., and the Protestant and Roman Catholic clergymen of the parish. The schools are in four departments—infants, boys, girls, and agricultural. A sound practical education is imparted wholly free. About 500 attend the various departments. The sewing of the girls is much commended. A farm of twenty acres has been procured at which the boys are taught practically as well as theoretically. Boarders are admitted to the latter department, and Mr. Naper pays for two pupils selected from the small tenantry on his estate.

It is not alone at children's festivals that the residents of the mansion exchange social courtesies with the inhabitants of the cottages. This is frequently done, and perhaps more especially at the harvest home—a time anxiously looked forward to as one of high enjoyment. The thus unbending of the rich takes nothing from their dignity; but we know it does increase the feeling of self respect in the working man, that acts as an elevating influence for many a day afterwards. We had heard so much of these harvest-home gatherings that we can picture to ourselves the whole scene: there are Milroy and his man for several days ornamenting the barn as for a feast of the aristocracy. When all is ready there are some 120 workmen sitting down to the loaded tables, and individually and collectively proving that Pat can make beef and other good things to disappear with as keen a relish as either Sandy or John. When the solids are disposed of, the ladies of the mansion acting as waitresses, the punch is introduced, and the cheering and hurrahing at the loyal and patriotic toasts would be sufficient to start every rat and mouse from the premises. The Chairman then gives the host and hostess, and the junior members of the family, and up rises the worthy proprietor to return thanks for the honour conferred, and in the most kindly way giving a lecture on social improvement, which we would like to see in print; telling them all about his new steam engine, which, though an assistant to labour, will, just as in the case of other machinery introduced, never cause a man less to be employed; and then descant on cottage building, labourers' comforts, and various modes and means of social progress; and then telling them that he depended on each and every one to lend a helping hand, clap their shoulders to the wheel, and with a strong pull, and a long pull, and a pull altogether, old Ireland would prosper; and concludes with drinking their good health, coupling with the toast the names of his head servants in all departments. We say nothing of the three-times-three and one-cheer-mors, amid which the fillers enter and say they are ready, the young ladies and gentlemen enjoying the entertainment as well as the humblest cottager; but this we will say, that if such landlords and masters are multiplied, and they are multiplying fast in Ireland, our ears must have been housed and our eyes had glamour thrown into them; and, if earnestness, and determination, and kindness on their part are met by gratitude, industry, and fidelity on the part of the employed, then the country must prosper, and the day be not far distant when the isle of Green Erin shall become socially and morally, as well as physically, "the first flower of the earth, the first gem of the sea."

R. FISH.

THE ILLUSTRATED BOUTQUET.—The quarterly Number for December, Part XLII. of this work, opens with a plate of two of Mr. Banks' best Fuchsias. Plate 58, *Fuchsia Minnie Banks*, "the most beautiful of the light-flowered section;" and *Fuchsia Comet*, or *Banks' Comet*, "the most effective, indeed, of all the dark Fuchsias." We have seen well-grown plants in bloom of both these Fuchsias, and can attest to Miss Sowerby's drawings of them, and to their superior merits. The "properties of *Colinus Verschaffeltii* as an effective-tinted plant, are next brought under review." Plate 59 exhibits five new varieties of *Epaeris*, in Mrs. Withers' best style. The names are *Fire-colour*, *Fireball*, *Sunset*, *Mont Blanc*, and *Butterfly*. Here we have the

fact before us, that *Epaeris* is more susceptible of improvement by cross-breeding than *Ileaths*. In addition to the five kinds represented, there is a list of the next best sixteen kinds of *Epaerises* for general purposes, a review of the whole family, with the best practical instructions for their growth and management throughout the year. Plate 60 represents the charming little *Sedum carneum var. guttatum* in a pot, also by Mrs. Withers. This is one of Dr. Siebold's plants from Japan, probably as hardy as *Sedum Sieboldii* itself. But to represent it to the mind's eye, we have only to say that the front row of a ribbon-border is of some variegated plant, which locks, at 20 yards distance, like the Variegated Alyssum. On coming up to it, however, we find it to be *Sedum carneum variegatum*, the carmine or fleshy colour is in the wavy branches and their subdivisions, the flowers being yellow. The lists of very elegant and tiny plants which follow the *Sedum*, and the suggestions how to dispose of them, for decoration, in and out of doors, in the air, on rocks, mounds, and beds of rustic baskets, are of themselves, worth the price of this Number to some people. Plate 61 will surprise many. Here we have six kinds of Tree Carnations and Tree Picotees, selected from the finest collection of the new race in Europe, and represented by Mrs. Withers as true as Nature. Here, also, follows an article on the new branch of conservatory decoration in winter and spring without forcing any of these "trees," which will be most welcome to the ladies and to many of their gardeners. Plate 62 exhibits—first, "the prettiest illustration of the genus *Cassia* yet known in gardens," said to be *Cassia australis*, var. *schimfolii*, a spring-flowering greenhouse plant; secondly, *Bouvardia Humboldtii*, recently introduced from Mexico. This is the most distinct kind in the genus, with large white flowers, and comes into bloom after *leiantha* and *longiflora*; and, thirdly, *Myosotis montana*, which is said to be an improved *Forget-me-not*, from *Myosotis alpestris* in some Belgian garden, whence it was recently introduced. The improvement consists of larger blossoms and a dwarfier habit of growth than that of *alpestris*. Here, after the ways of *Forget-me-not* have been treated of, we are told that "one of the finest species of *Forget-me-not*, as an early summer-flowering plant for parterres and beds, is the *Myosotis sylvatica* of gardens."

THE GLADIOLUS.

FEW flowers have made in so short a space of time such rapid progress in public favour as the *Glandulensis* varieties of the *Gladiolus*; and as this is the best period for making or adding to collections, it may not be out of place, with the experience of the last two years before us, to give a few hints as to its management and as to the additions that may be fitly made to a collection of them. In so doing I look at them as a florist's flower, and shall not attempt to enter into the question of their suitability for garden decoration. There are other and better hands capable of doing this, and I do not wish to go beyond my own province.

The history of the flower has been so recently given by Mr. Beaton, who, *au fait* in this as in all matters connected with plants, many years ago began the pleasant taste of hybridising, when the late Dean of Manchester, Dr. Herbert, was so successfully pursuing his experiments amongst bulbs. The French were beginning to draw our attention to the bulbs, and new varieties were reaching us from the other side, when our gracious Sovereign gave a great impulse to their culture by taking them under her special patronage. Their being placed on the royal table led the frequenters of the Court to follow the example set them, and a demand almost unprecedented in the history of flowers has arisen. Fortunately they increase very rapidly, and hence they are being generally distributed over the country; and before this unhappily war broke out in America were being eagerly sought for there, for one Paris firm this time last year was looking out for 30,000 bulbs to supply one order. Alas! now muskets and minnie balls would be more likely to command a sale.

There was an enterprising nurseryman who had been long known as a successful hybridiser—Mr. John Standish, of Bagshot, who was determined that our lively neighbours should not have all the benefit and glory; and as he had already been so eminently fortunate in *Fuchsias*—for Standishii was amongst the first of the new race, and as his hybrid *Rhododendrons* had shown that he knew how best to obtain form and colour combined with vigour of constitution—he set himself to the task.

In this he has succeeded beyond his expectations. Both last season and this have shown that he has not only equalled but distanced, especially in the matter of form, the foreign varieties. Monsieur Souche has been the most successful raiser there, and each year some of his varieties are introduced to us through the medium of the well-known Paris firm of Thibaut & Keteleer, of the Rue de Claronne. But I think we shall not have need to go across the water to supply our gardens.

With regard to form, for which I am a great stickler, regarding it as the first point in a flower, Mr. Eaton says the florists will never be able to make a circular Gladiolus. Perhaps not; but still there is a model which I think we may strive to attain to. As the bloom is composed of two triangles, we must look that the petals forming them be arranged regularly, and that they be broad, and not pointed, narrow, or jagged in the margin; and I believe that the more circular the throat of the flower is the greater will its beauty be.

Then substance must be obtained. We have it now in some of the varieties; and as they become plentiful flimsy flowers will be discarded. Nor do I think those kinds which partake too much of the oppositiflorous blood will last in favour long. They may many of them be very beautiful in colour and even in shape, but they are not the thing for a box of cut blooms; and therefore when we can get those which show entirely *en face*, we shall discard those *dosa-dos* gentlemen, or ladies, as the case may be; and I doubt not, as the flower is so tractable and exhibits such an endless variety of colours, shades, hues, tints, stripes, bars, &c., that by-and-by those only which fulfil these conditions will be retained. In the meantime, as the Irish saying runs, "We musn't throw away dirty water till we can get clean."

I would also add, as a requisite, that the flowers should be closely set together. If too far apart the beauty and symmetry of the flower are spoiled. These requirements may seem to some exigent; but I am sure in a few years time that we shall find many flowers now in repute discarded, because they do not possess qualities which now we are not so particular about, simply because the flower is a new candidate for the public favour.

Their cultivation and management has had some light thrown on it by the experience of the last two or three years. Mr. Standish, finding that they thrive so well in the light sandy soil of Bagshot, came to the conclusion that they did not like manure; and even recommended, where the soil was too rich to impoverish it by burning some. He now, however, thinks differently, and advises the addition of well-rotted manure to the bed. They will, in fact, do in any good, rich, light garden soil, but are impatient of bad drainage; and clay soils, therefore, will hardly grow them successfully. I would myself recommend that they be grown as carefully as we should grow a bed of Tulips or Ranunculuses, for they are assuredly worthy of our care.

The bed ought to be prepared now. The soil should be well turned over and exposed to the influence of the weather; and if it be not sufficiently rich, the addition of some well-rotted manure may now be made. In March or April, as the weather may best suit, the bulbs should be planted. Drills should be drawn across the bed (one 4 feet wide I should consider a good size), at a distance of 6 inches apart. The bulbs may be placed about 6 inches apart in the row and 3 inches deep, placing some silver sand under and over each bulb. Where the sorts are named the better plan would be to number them as in a Tulip-bed, and arrange them as to height where this can be done. They will require very little attention during the summer, save that which every gardener must consider of main importance—weeding and keeping the ground well mowed about. When the flower-stems begin to rise stakes should be placed, as high winds are very apt to twist them about and either loosen them or break them off. If any one have an awning either for Tulips or Picotees, I should say by all means put it over the Gladiolus-bed. Do not let it down save in heavy rains or during scorching sun. But I am quite sure they are flowers that will show the advantage of taking this trouble with them. And if the Tulip-awning be moveable it may as well be there as put by; and for this reason I would recommend the bed to be 1 foot wide, as that is the orthodox width of a Tulip-bed.

When the bloom is over and the foliage begins to decay the bulbs may be taken up; and their drying is a matter of some importance. They do not require, as some others, to be dried off gradually, as they then are apt to contract mildew, but if

should be done quickly. I have found that it is a very good plan to place each variety in a small flower-pot, and stand them at the far end of the greenhouse line, where the heat is moderate. They thus dry rapidly, and may then be placed in drawers, as Tulips are, or else in paper bags, and kept in a cool dry place until planting time comes round again.

As to *sorts*, the choice will depend on the pocket of the purchaser; and I therefore give three lists—the first comprising cheap varieties, mostly of foreign raising, which may be purchased at from 5s. to 10s. per dozen; the second, of more choice and new varieties of French origin; and the third, a selection of Mr. Standish's best flowers.

LIST NO. 1.

Brunschweizensis, deep crimson	Mathilde de Landvoisin, white, striped with carmine
Conrants fleurs, crimson	Monsieur Vinchon, rose, striped with deep salmon
Calandini seens, salmon rose	Nioun de l'Enclous, carnation rose
Don Juan, red	Oberin, purple, and white (curious)
Endymion, rose, lightly tinted with violet	Orlando, light orange red
G. lathée, flesh mottled with crimson	Princesse Mathilde, light rose and carmine
Hebe, pale flesh mottled with carmine	Sulphurais, sulphur
Fanny Rouget, rose, lower petals deeper	Vesuvius, deep glowing red

LIST NO. 2.

Achille, deep red, marked with white in the centre of each petal	Mademoiselle Marsault, flesh white carnine and violet spots
Berthe Rabourdin, pure white, spotted with carmine	Napoléon III., bright scarlet-striped
Docteur André, bright orange	Princesse Mathilde, light rose and carmine
Edith, carnation-striped	Reunbrant deep scarlet, very bright
Elorado, yellow, chocolate feather and stripes	Raphael, deep red vermilion
Favéne Donage, deep crimson, dark throat, one of the richest in colour	Solitaire, sulphur, with brownish feathers, nearly yellow
Isoline, carnation, violet spots	Solférino, orange scarlet violet, carmine spots
Le Quintin, bright light orange	Victor Yverde, bright red
Monsieur or Madame Lesclée, white, spotted with violet rose	Vulcan, scarlet, velvety purple

LIST NO. 3.

Agnes, pure white, rich crimson in the centre of each petal forming a star	Mnerva, clear white, with pink feathers and throat
Aurelian, scarlet, deeper in the throat	Monsieur Morris, scarlet centre, daisy markings
Basil, carnine, white centre, and deep crimson blotch	Mrs. Dolbrann, blush, striped with lake and crimson lip
Cura, white with yellowish tinge, beautiful light crimson star	Rosebud, scarlet, violet throat
Cordell, white, ruy throat and feathers	Roseberg, deep scarlet, blood colour
Dr. Hogg, deep crimson	Saints i Weymouth, brilliant scarlet, yellow throat
Goldier, lemon buff throat, pure marking	Theresa, white violet feathers
Ivanhoe, dark scarlet	The Galiph, creamy rose, golden tinge
Lady E. Seymour, pale buff, with pink tinge	Tom Moore, crimson, with violet crimson feathers
Leonaude, yellow, striped in each petal	Viola, delicate lemon, purple feathers

I may, perhaps, as a florist be too sanguine, but I believe we shall yet see flowers surpassing in beauty even these; and I cannot but think that if the public taste is roused to expect it, the greater care will be exercised by hybridisers to obtain form, colour, size, and substance. I may, perhaps, add that those who may desire to have a good and cheap bed, may do so very effectually by procuring some of the mixtures of Mr. Standish's seedling flowers, from which I had a very handsome selection the past season.—D., Deal.

OBTAINING FRUIT FROM NEGLECTED VINES.

Will you instruct me how I may obtain some fruit from any of my pot Vines this summer? Six or seven of them are from eyes a few years, and are not much thicker than a common pencil, and a few are old plants which have been grown on the "spur system." One or two I think have been forced in vinery, if I may guess by the roots on the Vines. They were out of doors all the summer and made little new wood. I have both old and young in a shed, but I can afford an intermediate-house or even a store for some of them if necessary. My object being to get a little fruit this season.—H. A. C.

[From what you say of the old Vines, we fear you would do no good with them, as the buds made last season, probably, would not be perfectly ripened. The wood of the young Vines, also, we fear is rather weak; but more will depend on the thorough ripeness and hardness of the wood than its mere thickness. If

the wood is hard and the eyes plump, you may give them a trial, and if they do not come up to your expectation you can prune back and grow for fine plants for another year. We would, therefore, place old and young together in a house at about 45°, and in a bottom depth of 70°, increasing the former to 60° in a month, and the latter to 80°. This will cause them to break early, and as soon as the shoots are 2 inches or 3 inches long you will know what they will do. No care now will make amends for want of proper care last season. If the plants were not matured nothing will make them produce fruit.]

THE IN-DOOR PLANT-CASE.—No. 7.

(Continued from page 291.)

ONE of the pleasantest uses to which to put this little in-door hothouse, is that of forcing some of our favourite flowers. Last spring I had a constant succession of Lilies of the Valley, with their fragrant blossoms, and their peculiarly fresh green leaves, and Sweet Briars also lent their delicious scent to every breath of air that passed their freshly-opened leaves.

Forcing generally requires much the same kind of treatment. A great deal depends on plants being well prepared, in which case it is slightly difficult to prevent their growing when given air and light with sufficient warmth and moisture. Lilies of the Valley do not like to be disturbed. They should be taken up from a long-standing bed and crushed into a pot—just a good-sized clod of earth with roots all undisturbed. These plants should stand out of doors till late in the autumn, being kept fairly dry, and then when the buds have a little begun to swell they should be placed in the warmest corner of the in-door plant-case, and not be allowed again to become quite dry. The corner away from the window, at the warmest end, does best for them at first. When fairly started a rather lighter place, and when growing up a cooler one, will be most appropriate. My Lilies last year were out in fire or six weeks from the time of putting them into the warm case, and nothing is more charming than the fresh waving masses of bright green leaves, which last for many weeks after the flowers are gone. The Sweet Briar, a short bushy plant being best, is even quicker in becoming pleasant, for the leaves are very sweet when they have scarcely begun to open. Sweet Verbena, and Sweet Woodruff, are other things that may be brought on delightfully, and Fairy Roses, and the pretty crimson China, if only we are careful to give air enough, Carnations, too, and Pinks, Heliotropes very easily, and the pretty, graceful *Deutzia gracilis*. After January begins, Achimenes, Gloxinias, Begonias, &c., may all be starting in well-drained pots of soil covered with cocoa-nut refuse, and many bedding plants may be also brought on for a stock of early cuttings.

HEATING HORTICULTURAL BUILDINGS BY GAS

Is a subject which will be of great interest to all amateurs, especially to those who have to mind their own fires. I have had considerable experience in applying gas for heating purposes, and shall be glad to give to your readers the result of my experience and experiments. First, let me say, that gas has much to recommend it; it can, in many places, be easily applied to a stove or hot-water apparatus. It is clean, inasmuch as it is not accompanied by dust and ashes, nor the trouble of kindling with the uncertainty of keeping in, which always makes a fire the source of anxiety. Gas is safe as soon as lighted, and will sustain a regular heat, which can easily be increased or diminished by the tap; but the application of it has its difficulties, which are but too often increased by parties trying to heat with gas, where, from some cause or other, fire-places or flues will not draw, or because there is not a chimney or due into which the smoke can be turned—in fact, after other appliances have failed gas is resorted to, because it will do, or rather is supposed to do, without a flue or chimney. Now, your readers would consider that only an idiot would think of lighting a fire in a room without a chimney to convey away the smoke and deleterious gas, and may probably be surprised to be told that such an act would be more sensible than attempting to produce an equal degree of warmth by gas without providing a flue, pipe, or chimney to convey away the invisible smoke and deleterious vapour created by the gas fire, which differs in no degree from a coal fire in its requirements of air to produce combustion and heat, but more

essentially requires a flue; for if smoke and sulphurous gas of a coal fire are obnoxious, the gas-fire vapour is most certainly more pernicious and deadly, as I shall presently show—in fact, it is the concentrated essence of all the most pernicious parts of ordinary smoke. I state this strongly, in order that none of your readers may be misled in their desire to produce a healthy, warm atmosphere; and I endeavor to use plain words, and avoid as much as possible chemical denominations, in order that I may be understood by all.

By the foregoing it may be seen that it is absolutely necessary that the gas-stove should have a flue; and this leads me to the stove or fire-place. I am of opinion that you may heat any kind of enclosed fire-place with gas. I have at this moment several modes or kinds working satisfactorily, and I purposely varied the mode in order to test the possibility of successfully using gas in any and every case, and certainly was interested in the experiments by the extraordinary result. Now, for a few lines I am compelled to use chemical words, but will try to simplify them as much as possible. A retort is a vessel with an outlet so placed that the gas generated from substances confined in it can pass out. Carbonic acid is a gas which is produced by burning the air we breathe, and, being heavier than the air, will sink rather than rise if ejected at any altitude. Heated air, being lighter than the atmosphere which surrounds it, rises. Gas is a vapour or a spirit, and can, like a liquid spirit, be diluted; it requires air to ignite it to produce light, and, by a proper admixture of air, will upon ignition produce more heat than light. This, of course, is an important point, for it is heat not light which is required; and, therefore, before describing the stove, I will say a few words about the best form of burners. I have found that the kind which produces the greatest heat is a sheet of copper gauze wire, confined in a ring or belt of about 3 inches circumference. The belt is about 3 inches broad, and is suspended over a ring of jets. If the light be applied to the jets the gas will, of course, burn through the wire with the usual flame; but if a light be applied above the gauze wire, the gas, or rather the gas mixed with the air under the gauze, will ignite and burn with a very pale blue flame, giving little light but great heat, and very little inclination to produce smoke or lamp-black like that produced by jets of gas burning under a plate. I have found that the above kind of burner is the best, and will now try to show an interesting experiment, which will be best explained by the annexed sketch, *fig. 1*. Upon lighting the burner at 2, the cylindrical stove speedily became hot, but the flue did not draw, and, in a short time, the gaslight went out. At first I imagined this arose from a down or back-draught; but, finding that lighted paper drew, I was led

1. Is the stove, a plain cylinder.
2. The gas burner.
3. The pipe or flue, marked 4, 8, and 12 feet high.

to examine the cause. Upon relighting the gas, I shortened the flue to 8, but found no advantage. I shortened it still lower. The gas burned more freely, but upon applying a lighted candle over the top of the flue, I was surprised to find that there was no up-draught; but accidentally passing the candle up the side of the flue from 3 to 4, the light, to my astonishment, went out when near, but below, the top of the flue, just below 4. Here, evidently was something for investigation. I soon found out my stove was merely a retort producing carbonic acid, which, from its gravity, could not be carried higher up the flue

than 4 by the heated air of the stove, that the hot air could lift it as high as 1, where it poured it over the sides of the flue, but in a state obnoxious to everything that lives, whether human beings or plants.

I then removed my flue-pipe to the top of the cylinder as in fig. 2, and found that to be a complete remedy, the heated air being sufficiently powerful to carry off all carbonic acid gas generated in the stove. I found by a series of experiments that I could extend the flue-pipe down into the cylindrical stove, as shown by the dotted lines at No. 2, to a certain distance, but no further; my object being to obtain as great a body heat as possible in the stove, before allowing the heated air to pass up the flue; and I am convinced that the whole secret of properly using gas for heating purposes lies in proper provision being made for the escape of the carbonic acid which is generated by all gas-stoves. I have shown how it is produced, and how it may be conveyed away. I have now four gas-stoves, of different descriptions, working satisfactorily, but every one required a peculiar and separate adjusting and regulating. In each, at first I had to contend with the tendency to produce carbonic acid, but found in each case that a proper and easy adjustment of the flue produced the remedy. The presence of carbonic acid is easily detected—the light will burn dim or be extinguished. If you fancy that a down-draught has blown out your gas, test the draught with a lighted candle; if it stands that test, introduce a lighted candle into the gas-stove when it is lighted, and if you find the candle dimmed or extinguished in the upper part of the stove, rely upon it that your flue or pipe is not sufficiently large; by in adjusting the size of pipe, care must be taken not to make it too large, for in that case a large proportion of heat would escape up it. The point required is to retain as much heated air as possible, and to allow only the sufficient quantity to pass to carry off the carbonic acid. I have illustrated my experiments by a stove of a cylindrical form, but I am disposed to think that the "Gill" stove is the best external form, for it presents the greatest amount of heated surface to the atmosphere. I warm the hall of my house with one, heated by a single gas-burner, and this, too, in a place where a coal fire gave great trouble from down-draught; but stoves of this description are expensive, and a simple cylinder with an outer casing about 2 inches larger than the minor one, will create a warm current of air to flow between the two. However, the gas-burners can be applied to any form of closed stove, provided that means are taken to prevent the too speedy escape of the heat up the flue. This may best be done by contracting the upper part of the mouth of the flue, or placing there a damper. It is also well to avail of any adjacent chimney-flue into which the pipe or flue can be turned.

I may state as a proof how generally the heat may be applied, that I warm my bedroom; an orchard-house, 30 feet by 14 feet broad and 6 feet high at the sides, I use it for a drying closet, and the "Gill" stove kept my hall at a pleasant temperature during the whole of the long frost last winter, burning night and day, without ever failing, without any attention. Let those who have to keep an ordinary fire lighted think of that. Now, I may be told that this is all very well, but that it is a costly and an expensive mode of obtaining heat. I am prepared to contend that it is not more costly than other modes, provided proper precautions are taken. The supply of gas ought to be conveyed through a regulator, to check the excessive pressure which in many places forces the gas quicker through the pipes and burners than it can be consumed. The pressure may arise from many causes; if the manager of the gas manufactory chooses, he can put it on, or if your locality be very high the pressure will be

greater than on those who are lower. In fact, there are so many causes of pressure that it is very needful, if economy is studied, to have gas-regulators wherever gas is used in any way.

From the foregoing, I think your readers may see that gas is applicable for warming conservatories and similar horticultural edifices; and in conclusion let me remark, that I am not either a chemist or a gasfitter, but an amateur, and that any of your readers may accomplish with ease what I have effected.—W. X. W.

EFFECTS OF THE WINTER OF 1860-61 ON PLANTS AT TORQUAY.

As it may be interesting to some of your readers to know what plants, shrubs, &c., withstood the very severe winter of 1860-61 in this climate without any protection whatever, I subjoin a list of such as I have in my small grounds, all of which stood without a change of foliage, excepting such as I have noted. The plants were well established, but none had been planted more than three years, some not so long. My house is situate rather more than a mile from the sea, and stands on an elevation of about 350 feet above it. I am sheltered by rising ground and a small plantation from the north, north-east, and north-west, but fully open without any protection whatever to the east, south, and west. I marked the thermometer as low as 23°, north aspect, at 8 A.M.; but I believe in my immediate neighbourhood it fell as low as 17°.—J. M., Torquay.

Pinus insignis	Taxodium distichum, deciduous
Cupressus macrocarpa and Lustranea (Cedar of Goa)	Spiraea prunifolia flore pleno
Ligustrum japonicum	Pachiana imbricata
Eucalyptus maculata	Veronica, blue, pink, and white, very much cut up, apparently almost killed, now quite recovered. The blue and pink at the present time in beautiful flower.
Euonymus albertianus, very much cut up, lost all their leaves, now quite recovered	Aristolotta
Coronilla, in bloom nearly all the winter	Aranea, 7 feet high, transplanted in June, 1860
Abelia uniflora	Arbor Vitae
Swammerdamia antennaria	Decidua
Stantonia latifolia, against a south wall, blossomed in March	Viburnum sinensis
Paulownia imperialis, deciduous	Magnolia grandiflora
Juniperus chinensis	Acacia Brownii
Mespilus diffusa	Griselinia littoralis
Photinia serrulata	Myrtus punctata
Persea macronota	Eugenia Ugni
Ceanothus papillosus, against a south wall	Ericas, a few hardy ones
Berberis Darwini, Fortune, and aquifolia	Passion-Flowers
Kalmia latifolia	Clematis
Dentzia graecis	Jasmines
	Honeysuckles, French and common

My Roses did not suffer in the least; nor did the Portugal Laurel, common Laurel, Laurustinus, or Bay. I lost Genista, Acacia armata, and another delicate Acacia; also several seedling Australian shrubs which had withstood the previous winter.

INCREASING TEMPERATURE OF A PINERY.

In the place I have lately come to there is a pinery about 24 feet in length, in which, of course, are grown plants of all sizes, including fruiting plants. I have cut some very nice fruit during the three months I have been here, and have some very good ones ripening, but some lately started do not seem to swell fast enough to suit me. The mode of heating is by a flue, and it only runs along the front path, so that there is nothing but the top to give off heat, and I cannot, by constant and almost continual attention to the fire, night and day, raise the temperature higher than from 60° to 65°, without sun. I have managed to keep it from 55° to 60° during the nights. No plants can look better, but do you think it hot enough? The pit was not taken out and fresh tan added from the end of last February until I came at the end of September, and the back of the pit seems rather cold where the fruiting plants are.—A YOUNG GARDENER.

[It is as well not to have plants fast started. However, they would be as well not to be below 60° at night; but 55° would do for the general stock, provided the moisture at the roots and in the air is proportionately small. You could increase the bottom heat by adding fresh fermenting tan. If the flue, however, goes only in front, and forms part of the pathway, you will have some trouble in keeping up heat, unless the sides of the flue act also on the pathway, by the earth being sloped

it as an inhabitant of that island. But this summer, Mr. Jackson Dawson, a young gardener, has brought us specimens and living plants (both flowering stocks and young seedlings) from Tewksbury, Mass., where the plant occurs rather abundantly over about half an acre of rather boggy ground, along with *Andromeda celyculata*, *Azalea viscosa*, *Kalmia angustifolia*, *Gratiola aurea*, &c., apparently as much at home as any of these. The station is about half a mile from the State Almshouse. Certainly this is as unlikely a plant, and as unlikely a place for it to have been introduced by man, either designedly or accidentally, as can well be imagined. From the age of the plants, it must have been there for at least a dozen years; indeed, it must have been noticed and recognised, two years ago, by a Scotch farmer of the vicinity, well pleased to place his foot once more on his native Heather."

VINES IN ORCHARD-HOUSES.

I SEE a remark (page 271) in your Number for December 31, "In the meanwhile, as shade is beneficial in hot, clear, sunny weather, there cannot be a more beautiful and at the same time more useful mode of obtaining that shade than by planting the more hardy kinds of Vines for that purpose." I have no hesitation in saying this will be found incorrect, and that all shade is injurious to the Peach in an orchard-house. I do not say a Vine or Vines may not be planted in a house devoted to this mode of culture; but that Peaches and Nectarines shaded will be inferior. No summer will be found too hot, no light too strong to have this fruit in perfection.

The value of orchard-houses is but just beginning to be recognised by those who know most about them; few have been built which will not be wished larger and better. A large house costs less in proportion than a small one, cannot be too long, and, up to 30 feet (which I think the maximum) cannot be too wide. If it stands with one end to the south, the northern half may be planted with Vines, the south end filled with Peaches, &c. In such a house White Muscadine, Black Hamburg, Chasselas Rose Royale, and other hardy Grapes may be produced in perfection as far north as this without fire heat.

We only want orchard-houses to be moveable to meet the case of those who are tenants, and do not like to build on other persons' property, and they will spring up in numbers all over the country. I have for the last three years been trying to induce my builder to carry out a plan of a moveable house, and I am glad to say he is now building one; so we shall soon see the effect.—J. R. PEARSON, *Chilwell*.

GLAZED WALL FOR A VINERY.

I HAVE erected a vinery, perhaps not on a new plan, but on one seldom adopted. The situation is a brick wall, facing due south: 32 feet is the length, and nearly 10 feet the height. The front of the glass is founded on a simple stone edging (not a wall) of substantial stones, averaging about 1 foot below the surface. On this is laid a menel batten from end to end, in which menel posts are morticed every 6 feet or so, as the chief supports of the roof, which is of good pitch—i. e., the slope is about from 9 feet 6 inches at the back to 6 feet 6 inches in the front, with a length of rafter of less than 4 feet. I thus have room enough inside to work at thinning, pruning, &c. The Vines are planted inside against the wall, at 2 feet apart or thereabouts. I shall have two rods from each, with a run of from 9 feet to 10 feet each. The root foundation being only 1 foot or little more in depth, the roots of the Vines pass underneath. They thus have a choice of inside as well as outside border. I have nothing running up the front glass (6 feet 6 inches high), or on the rafters (1 foot), so that I have no obstruction to light. From this plan I expect to get the whole of the inside border for either forcing Strawberries or any fruit or flowers of dwarf habit, and either in pots or otherwise. I shall be glad of any suggestions or remarks. It seems to me that where a promenade is not wanted, space is economised; for it is well known that where a vinery is built in the ordinary way with the Vines up the rafters, neither the floor of it nor the back wall are of any use. After the Vines have fully covered the house I expect to take twenty bunches at least from each Vine, and have the full use of the floor or border of this vinery just as if I had no Vines in it, for the roots will be in the open garden, in which I make a border 300 square feet. The substratum of the soil

is a pure sand at 18 inches depth, and this sand is probably 20 feet deep.—A SUBSCRIBER.

[We have no doubt your plan will answer well enough, but it would not suit in general circumstances where people like to walk through their houses. We presume that, to have your house full, you will fill and empty by the front glass. We have no doubt the Vines will answer, but one rod or stem will be enough in 2 feet. If so thick as you propose we do not know where the side bearing-spurs are to go. Little can be done under Vines when they cover the roof; but we have seen Vines on the back wall and Vines up the roof, and both do well when the Vines were 4½ feet to 5 feet apart, and at all times, except when the Vines are approaching maturity, the floor pretty well covered as well. We are, however, obliged for your plan, which would no doubt suit many that did not care for walking much in a house provided they got a fair amount of fruit out of it. The houses at Trenton are many of them on a similar plan, only much more lofty; and in addition to the fruit at the back there is also a low trellis in front—not so high as to keep the sun from the back wall. We should advise keeping all the front plants in pots; and then, in addition to Strawberries, you may have dwarf plants of Currants, Gooseberries, Apricots, Peaches, Cherries, Plums, &c.]

BORDER REQUIRED BY CLIMBERS.

I AM rather alarmed at a statement in your paper of Dec. 31st, that "no climbers whatever will do in a border 9 inches wide," that being exactly the width of the border against the back of my greenhouse. The climbers in it were planted last summer and apparently flourish. Will you inform me whether your statement applies to a greenhouse; and if so, what is the least width of border in which they will do?—J. R. W.

[No permanent climber whatever will do in a nine-inch border, supposing the whole of the roots are confined to that space. It sometimes happens that the soil next to a made border is better for some climbers than the border itself; in such a case a four-inch-wide border would do. But if the border is as if it were between two walls, and only 9 inches wide, none but summer or temporary climbers—such as *Maurandias* and the like, will thrive in it longer than to just establish themselves, and flower once or twice, and then become the prey of all the scales and insects to which the plants are liable. To the query, What is the least width in which climbers would flourish? no one can reply decidedly. It depends entirely on what kinds of climbers the border is for. A border 1 foot wide and 18 inches deep, and not much under 20 feet in length would do for a great number of climbers; and some climbers—as the *Passion-Flower*, *Tarsonias*, all the new race of *Clematises* from Japan, with a few of the old ones, and some others, would do there much better than in a wider border. But what about the under side of such borders? If the roots of greedy climbers, which are very hardy, can run into subsoil, who knows how far they may go? Then, if the border is wide enough to admit room for the growth of the stem at the surface of the soil it is enough. It is bad gardening, however, to allow any but the coarsest climbers to run into a bad bottom soil; that is more than one-half the cause of some climbers never blossoming freely, and why others are so peculiarly liable to the attacks of insects and mildew.]

PRUNING THE PLUM.

IN almost every garden we find the Plum tree trained in the fan-shaped form, and nurserymen invariably prepare their trees for this mode of training; but notwithstanding its general adoption, there are great objections to it for the Plum, the more vertical and central shoots growing with a degree of vigour inconsistent with fruitfulness; and, when laid in at length, being liable to produce but few irregularly-placed spurs. Something may be done to avert this result by carefully bending the points of such shoots before they break. The horizontal mode of training offers the same advantages for this fruit which it does for the Pear and Apple—namely, that all the parts of the tree are more equally balanced by its adoption. As we have described the formation of the tree (under Pear), we need not here advert to it, and for those who would train in the fan-shaped manner, the instructions for the Peach are sufficient.

We have then to explain the mode of bearing, and to detail

the summer and winter management of a tree, which we will suppose to be already formed upon either plan, although we think the horizontal ought to be preferred to the fan mode.

The fruit of the Plum is produced naturally upon short spurs along the two-year, three-year, or older branches. *Fig. 1* represents a two-year-old branch, in which *a, a, a,* are blossom-

Fig. 2.

Fig. 1.

buds. *Fig. 2* represents a spur from an older branch, which has received treatment in past years from the hand of the pruner. To insure a regular supply of these fruit-bearing studs, or spurs, and to keep them as close as possible to the main branches, must be the aim of those who desire to have fruit. As the Plum is a tree which produces excessively luxuriant shoots when severely pruned, we advise the same plan of pinching the summer shoots, three or four joints in length, as we have for the Pear, instead of cutting them out at midsummer almost to their bases, and also to stop the leading shoots once or twice in the growing season, according to circumstances. Trees so treated will always present a large choice of well-placed fruitful buds, which will afford an opportunity of keeping the spurs shortened back so as to be close to the wall, or what is understood in our vernacular phraseology as applied to gardening matters, by the term "at home."

The Plum tree is well adapted for forming pyramids, which are valuable adjuncts to a small garden. Root-pruning is most essential, and should be frequently resorted to.

THE APRICOT.

It has long been the practice to train this tree in the fan-shaped manner, and to that subject we need not revert. The fruit of the Apricot is produced upon the last year's shoots, and also upon short spurs of the shoots of former years. The latter were more generally encouraged by our older practitioners, but it is now more usual to treat the tree in a similar manner to the Peach. Our object is, therefore, to insure a plentiful supply of young wood (and a succession of it) all over the tree. Great care should be taken to avert the necessity of removing large branches, as it is most susceptible of injury from this cause.

The reason why young wood is preferred to spurs is, that the Apricot tree, not being indigenous, but a native of "the land of the sun," is not only very excitable, but very tender; and, of course, very unsuited to withstand the rigour of our late spring frosts, alternating, as they often do, with the brilliant sunny days which we occasionally get in March. As the blossom-buds of the young shoots, when nailed or tied in, are in close contact with the wall, they are much more secure than those which are borne on projecting spurs: and hence this preference. *Fig. 3*

Fig. 4.

Fig. 3.

represents a branch of an Apricot tree, in which *A, A,* is one-year-old wood, and *B* two-year-old wood; *a, a,* are blossom-buds, and *b, b,* wood-buds. The summer pruning of Apricot trees consists principally of the disbudbing process, removing and thinning the superfluous shoots, and keeping only the well-situated,

replacing shoots at a sufficient distance from each other to permit every leaf which is retained to perform its functions. The young wood must be shortened with discretion, applying the process with less severity to strong than weak shoots, and always taking care to shorten a sufficient number of the lowermost shoots to prevent the occurrence of any blank or nakedness; in fine, to keep the tree "at home."

The Moorpark (the best of Apricots) is very apt to lose its limbs suddenly, and thus many a fine symmetrical tree is spoiled. We opine that the mischief is occasioned by frost, in early spring, bursting the sap vessels. (There are some who take a different view of the subject. For the information of those who, after pruning, nursing, and watching their fruit trees for years, meet with this disappointment, we may mention that Mr. Rivers, of Sawbridgeworth, recommends the Gros Rouge, or large red, as "an excellent variety, hardier than the Moorpark.")

THE CHERRY.

Fig. 4 represents a two-year-old branch of a Cherry tree, in which *a* is a natural fruit-spur, and *b*, *b*, spurs in process of formation, from the base of the young wood. Fig. 5 is a spur also,

Fig. 5.

which has been subjected to pruning. It is thus evident that the fruit is borne upon the two-year-old wood and that of greater age. Fan-shaped training is most in use, and nurserymen generally prepare their trees for this mode. Having shaped the principal branches into a good fan, the art of the pruner has only to deal with the spurs by cutting out the old ones and substituting others at their base, in the kinds known as the Dukes and Hearts; but some of the kinds produce very large foliage, and require the distance between the branches to be greater than usually given.—H. BAILEY, *Gardener, Nuneham.*

A NEW DODGE FOR WINTER-FLOWERING FUCHSIAS.

THAT beautiful winter-flowering Fuchsia that Mr. Beaton mentioned the other week, called *Dominiana*, which so few people can flower well, is one of the best stocks to graft any of the others on as standards, or for pillars in a conservatory, or to spur-in on the rafters. I have had some flowering all the winter.

Strike it from cuttings, take all the eyes out at the bottom, and pull all the lateral shoots out as they grow. If you do it well it will grow from 6 feet to 10 feet high the first summer, and then graft it the following winter. They grow and flower in the temperature that they would cast all their leaves in on their own roots.—WM. SMITH, *York.*

ORNAMENTAL FLOWER-STAND.

PROFESSOR MOREEN, in "La Belgique Horticole," has given the annexed form of Ornamental Flower-stand, which combines representations of a light iron table, a wire flower-basket, and ornamental Belgian flower-pot of very neat design; and an example of one of the dwarf Pinks of Verriers. We give his description of these articles:—

Ornamental Flower-pots.—These are manufactured by Messrs. Bosch, brothers of Hainaut, Belgium, and are well suited, from their ornamental character, for growing plants in rooms. They are ornamented with chaste designs, in relief, in imitation of

different objects, as well as flowers and foliage. The colours which harmonise best with the flowers are blended as well as possible. The pots which are to be preferred from their artistic value, are those which have a cinder grey, or slightly brown colour, with the designs of a light chocolate colour—that is, such as is produced when coffee is well mixed with milk. The figure represents such a pot placed on a bed of *Lycopodium*. [These pots, we believe, have been introduced to England.]

Wire Flower-baskets.—The trellis makers of Belgium construct the wire baskets with a limb or border of leaves made of tin. The bottom is filled with soil, on a layer of chips of wood, and on this a beautiful green carpet of some of the dwarf *Lycopodiums* is grown and preserved in a fresh state all the year. When this *Lycopod*, which is so easily propagated by cuttings, has spread well out, and formed its branches in festoons, the effect is very pleasing. It may be grown thus in a few weeks in a situation which is warm and close, but not much exposed to the rays of the sun. Frequent waterings are necessary. In the middle of a bed of this moss may be placed one of the ornamented pots, containing some well-grown plant.

Iron Table, or Stand.—The under part of the design represents a table made of cast iron, and having an ornamental margin of wire. The article is solid, and, with the other accompaniments,

forms a very ornamental object, and is otherwise not unfavourable to the growth of the plants placed on it, so long as the rays of the sun are not permitted to fall on it. This table is slightly and regularly inclined towards the centre, from which a pipe leads down the stock, and having a hole at the bottom for the escape of water. This mechanism permits simple drainage, and the water which falls in the operation of supplying the plants, empties into a vessel placed underneath the tripod. The design of the tables may be greatly varied. Those which are lightest are generally preferred. No parlour or drawing-room should be without such a stand as we have just described.—(*Gardeners' Magazine of Botany*.)

PLANTS FOR COVERING A WALL.

I HAVE a wall facing almost due south, covered with wire trelliswork. It is exposed to a mountain breeze. What plants can you recommend for it? Also, what Roses would be suitable? I do not care for the common climbers, either Ayreshire or evergreen. Which of the Bankians are most likely to blow?—**A CONSTANT SUBSCRIBER IN IRELAND.**

[The white and the yellow Bankian Roses would do well on your trellised wall if you allow each of them to occupy at least 10 feet of its length, and had them pruned when they had done flowering, instead of in the winter and spring. The double Macartney Rose would also be at home there, and the three Roses would need a run of 30 feet in length, supposing the height of the trellis to be 12 feet. Then if you cannot afford so much space do not plant the Roses at all. The blue Passion-Flower, and the newer Clematises, as Clematis lanuginosa, the finest of them all; C. venosa, one of great beauty. The old Begonia or Tecoma grandiflora, is still not surpassed by any new hardy climber, where it is properly treated on a south wall.]

For the bottom-of-wall plants and for temporary covering, whilst permanent climbers are filling up take the Clematises which run in the way of *corucla*, *no cura ca odorata*, *azurea*, *Amelia*, and *Louisa*, Fortune's double-flowering Peaches from China; the new varieties of *Cydonia japonica* from Paris; *Escallonia macrantha*; *Forstya viridissima*, on west, east, and north walls, the south is too hot for it in a dry climate; *Eurybia japonica* and *illicifolia*, very free, very rare to be seen, very easy to do or undo, and very good bedding plants for the whole month of May. And for summer or temporary climbers take *Mansuriana* and *Lophospermum* of kinds; *Tropaeolum* of the hybrids from Lobbianum; *Pycnogenae suavis*, a very fast grower, with the looks of a gentee *Bryonia*, having flowers as white as snow, and as fragrant in the gloaming as those of *Chimonanthus fragrans* itself, but not much bigger than the flowers of the Grape Vine; and for the north side of a house, nothing is more sure to grow and run about, and bloom most abundantly the whole summer, than *Calystegia pubescens* simplex. Clematis Sieboldi to be planted by the side of the Passion-Flower, and to be trained over it. The flowers of this Clematis are of the looks of a Passion-Flower so much that they might be mistaken at a short distance. *Cotoneaster Simmonsi*, the best wall plant in the order it belongs to. *Chimonanthus fragrans*, which ought to be on every house front in the three kingdoms, and on the east and west fronts of some of them also, and also on the north front of every house south of London. *Jasminum nudiflorum* on the four walls of a house would bloom on some of them from October to April. Ours on the north wall is now one mass of yellow, and has been so since the 1st of November, and will last to the end of February; but the place is well sheltered from the east. *Lonicera flexuosa*, *alias japonica*, and *alias Evergreen Honey-suckle*, is another which no plant-wall should miss. *Ceanothus azureus*, the finest of that genus, but the most tender of them all, and requiring some protection in all parts of England, but is surely worthy of as much care as a Myrtle. *Ceanothus papillosus* and *floribundus*, are both good also.]

THE OLD-FASHIONED APPLE-SCOOP.

Most persons have met with the anecdote of the quaker, who hearing a young and conceited man dilating on the intellectual improvement of modern times, and expressing his conviction that if Solomon were now alive he would be considered a fool, said he quite agreed with him, and could not help thinking what a very great fool the young man's grandfather must have

been. Now, without wishing to deny that we live in an age of great progress, I think in some things our ancestors were wiser than we are; at my rate, my grandmother at eighty knew how to enjoy an Apple. I think I see her with a small silver scoop enjoying a fine *Whiston Pippin* by the Christmas fire. But in this age of simulated youth and false teeth, it would not do to eat an indigestible Apple, so many a person but little passed the middle age never eats one.

What a strange thing it is that an Allwise Providence has sent us fruit in the autumn when our bodies from the constant loss of fluid are generally in too alkaline a condition, and that so pleasant a remedy should be neglected! But, with all our boasted reason we are creatures of instinct, and what disagrees with us soon ceases to please. It is not every stomach which can digest an unmanicured Apple. So if we do not take the acids so kindly provided for us, why a fit of English cholera will, perhaps, carry away the superabundant alkali. It is true the stomach may be disordered by unripe fruit, still more easily by fruit in a state of decay; but is that a reason for eating none? I believe the years Asiatic cholera was so prevalent in England were bad fruit seasons; and have heard a medical man say it spread the habitual drinkers of cider. Whether this be true or not, I intend when an old man to set up a scoop and enjoy my Apple when I cannot procure a first-rate Pear.—**J. R. PEARSON, Chilwell.**

SUPERPHOSPHATE OF LIME.

I HAVE often been told that superphosphate of lime is a manure the benefit arising from which is perceptible on two or three successive crops. I have noticed this to be the fact on the land of some of my neighbours; but, with me, I have not found that it benefited even the crop which followed my Potatoes. Why is this? I should tell you, that the Superphosphate sold to me was nearly entirely soluble in water.—**SUTTON.**

[The best answer we can give you is in the following extract from a sensible little pamphlet, by Mr. E. Purser, jun., Chemist to the London Manure Company, and entitled "A Few Plain Hints on Artificial Manures, their Theory and Application:—"

"It is well known that bones are slow in their action. The reason for this is, that their most valuable mineral constituent, the phosphate of lime, is in such a state that it does not readily enter into association with the plant. Now, if bones, or any substance containing phosphate of lime, are treated with some strong acid, such as sulphuric, a certain portion of the lime that holds the phosphoric acid is set free, and the remainder rendered soluble in water. On this fact the manufacturer of superphosphate of lime works. He obtains substances containing phosphate of lime, dissolves a certain portion of it in the strong acid, and so makes superphosphate. From this it will be argued, that the value of a superphosphate consists in the amount of soluble it contains; and this, so far as it regards superphosphate made from carbonate or apatite, is an absolutely true. In these substances the phosphoric acid is so closely united with the lime, that, without it is rendered soluble, it lies in the ground inert and is useless to the farmer. Not so, however, in that made from bone; for in this case the insoluble, consisting of bones, decomposes slowly, and by the time the soluble is exhausted, comes into action, so not only carries the root on to maturity, but leaves valuable manure in the soil for the succeeding crop. At the present time, farmers are insisting on having a very large amount of soluble. This I do not think is good economy, for the rain must wash a considerable portion of the soluble away, which must either sink down to a greater depth in the ground than the root penetrates, or it must be carried off in the drainage water."

"I consider it better for a farmer either to buy a manure guaranteed to be made entirely from bone, or to go to a respectable manufacturer who is enabled to use a large amount of bone in his superphosphate. It is found, from experience, that a manure containing from 18 per cent. to 20 per cent. soluble, with about 12 per cent. to 14 per cent. insoluble, mostly bone, will give a more satisfactory result than a manure made nearly entirely, containing 22 to 24 per cent. soluble."

"Nine-tenths of the superphosphate that is made are used for the cultivation of root crops, their large surfaces of leaf enabling them to extract nearly sufficient ammonia from the atmosphere for their successful growth."

MANGLES' VARIEGATED GERANIUM.

It seems because I said that I expected to be able to dress him in a gold-laced coat, everybody is on tiptoe to see him.

Well, whoever should be so fortunate as to see him first would see a sight better worth one hundred guineas than 100,000 of *Gazania splendens*.

The logic of my argument was, as I had crossed it once it was possible to cross it a ain. That I failed in part only gave a greater stimulus to further exertion. Mr. Beston's ideas of preparatory treatment bespeak an old practitioner; but for his information and all concerned, I will just state what I did it

with, and it will be seen to corroborate in part Mr. Beaton's views on the subject.

In the first place, mine were all old plants taken up and cut-in during the previous autumn, and are served the same again. In the second, they were planted in dry, warm, gravelly soil. Having a few more than were wanted, they were left in pots.

Seeing in THE JOURNAL OF HORTICULTURE, and in notices to correspondents, that this Geranium would not cross with any Geranium in cultivation, I thought I would try the truth of that assertion, and so began upon the spur of the moment without any preparation, and tried those in the pots first, some under glass, and some outside, with every Geranium I had about the place for two or three successive days; but the plants in pots resisted all my attempts, so I then went to the flower-beds, and tried there exactly after the same manner as I had tried on those in pots, and two only taking, and those two were fertilized with the short stamens of Golden Chain. So it will be seen that it was not the result of a cross that I looked at so much as the fact itself.

What I have advanced upon the results of crossing that Geranium was an after-thought arising out of that fact.

I am inclined still to lay great stress upon heat. I have several ways in progress and in my mind's eye of attaining the desired end, and if I should be the successful one, I will report them. In the meantime the field is open to all who will bring their wits into operation, and as the Yorkshire phrase is (after telling them all one knows upon the subject), "it is a daft head that has no ingenuity of its own."

From what I have advanced, Mr. Beaton will be able to gather that it was not a premeditated experiment, and that it was the first of the kind, so that I am not in a position to dictate the best way. Did I attempt to do so, it would be theory, which is not wanted.

I believe if I were in possession of the original from Mangles' sported (not the green shoots it sometimes sends out, they are equally as barren as itself) there would be not the least difficulty about the matter. Is it in cultivation? What is its history? If any one can answer those questions I shall feel greatly obliged. —WILLIAM SMITH, York.

ALLEN'S HOT-WATER APPARATUS.

I SHALL be obliged if you could inform me whether that part of the hot-water apparatus figured by Mr. Allen, at page 134, Vol. XXV. of THE COTTAGE GARDENER, and placed above the damper containing the feeding-door is made of iron, and if so, is it cast separately, and how is it fixed? I should also like to know how often it is absolutely necessary to replenish the fire to prevent its going out. I presume the boiler does not require surrounding with brick.

In the event of these inquiries being found impracticable to be answered, would you inform me where such moveable stove boilers as Mr. Fish describes, at page 270 of the same volume of THE COTTAGE GARDENER, are likely to be procured?—G. S.

[We wish that Mr. Allen would answer the above definitely. His stove is set on brick and with brick surroundings. We presume the part above the damper, which, in fact, acts as doorway, is of iron, and cast separately from the rest, and will be close enough if merely set on the top of the boiler, and would just be more secure if a screw was placed in it there. Boilers without feet would require some base to stand on. To do without anything of the kind, they must have feet like an iron stove, and this Mr. Riddell's stove, so often advertised, has. There are several others, as a conical boiler, made by Lynch White, Upper Ground Street, London, S.; but in all such cases it would be advisable to have the boiler in the house, or so that the heat should be got in, as detailed in the page referred to. Not the least important feature in Mr. Allen's boiler, is the damper, and the small draught given, especially after the fire is lighted. We should only disappoint our inquirer were we to state how often such a boiler or any other needs attending to. That will depend on the fuel used and the skill of the fireman; and telling how often such fires need attending, without reference to these matters and the state of the weather, would do more harm than good.]

TRADE LISTS RECEIVED.

James Carter & Co.'s Gardeners' and Farmers' Trade-Memum, High Holborn, London.—This is one of the very best catalogues

of seeds and plants issued by the florists and nurserymen of the three kingdoms. Very few are the purchasable plants not to be found in its columns, and much is the useful information which it gives about them. It tells their botanical classification, native country, hardness and duration, colour, height, flowering month, and treatment, though under the last head the information is necessarily brief. It includes lists for the flower garden, kitchen garden, and farm; besides a calendar of monthly operations, and illustrations of some new plants.

WORK FOR THE WEEK.

KITCHEN GARDEN.

MANURING and trenching the ground as fast as the crops are cleared off will still be the principal occupations here. Turn over compost-heaps during frost to be protected from rain and snow, and procure a fresh supply if needed; do not miss the opportunity of forking over previously-trenched ground on frosty mornings. *Cauliflowers*, the plants in frames to be protected from frost; those that are growing in pots to be placed in any cool house from which the frost is excluded. *Horseradish*, make plantations in deeply-trenched and well-manured ground if you would have it fine. *Onions*, sow in a warm corner for early spring use, and plant out small ones of last year's growth for the same purpose, and to bulb for kitchen use; the soil to be light and rich. *Mushrooms*, beds out of doors to be well protected from frost; if the covering is very damp remove it, and replace it with dry. Save horse-droppings for early beds. *Peas* and *Beans*, sow in pots, or boxes, or on strips of turf, a moderate quantity for transplanting; place them where there is a gentle heat, and, when about an inch high, remove them to a cold frame (secure from frost) to harden. The value of a little seed is as nothing compared with the loss of an early crop: and, if the weather proves favourable, these transplanted ones will come in as soon, very often sooner, than those sown at the latter end of the year. *Rhubarb*, continue to take up roots, and plant in pots or boxes for a successional supply; place them in some warm place such as a Mushroom-house at work. *Sea-kale*, see that the fermenting material about it does not get too hot, begin in time and give it a slow gentle heat; cover up in succession, taking care to place pots, or a substitute, over the crowns to keep them from the fermenting matter. *Shallots* and *Garlic*, plant out in dry rich soil, draw a small drill and fill it with wood ashes or charred refuse, and lay the bulbs thereon, but do not cover them: they will, by-and-by, require a slight pressing down. *Spinach*, remove carefully all decayed leaves, and stir the ground the first favourable opportunity. *Salading*, keep a succession sown in pots or boxes, and attend to the protection of Lettuces, Endive, Radishes, &c., in severe weather.

FLOWER GARDEN.

The beds intended for Ranunculuses to be well turned over and thus aired in frosty weather, and, where necessary, renovated with fresh soil or compost. The beds of Tulips to be covered during severe frost, and also from heavy rains, which, at this season, are very prejudicial to them. The Pink and Pansy-beds to be examined, and all plants that are at all loose to be carefully fastened. Sweep lawns occasionally to clear them of fallen bits of branches, &c.; and use the roller here, and on gravel frequently, to secure a fine smooth surface. If any portion of the lawn is uneven it should be lifted and relaid to give a more pleasing appearance to it, and to make the mowing less tedious and difficult. Avoid wheeling on grass. See that the common Laurel in the shrubberies is confined within due limits.

FRUIT GARDEN.

The pruning of fruit trees should not be delayed till late in the season, the trees suffer when the operation is performed after the sap has risen. If not done in the autumn, prepare and wheel in soil for fruit trees which are to be removed, or for filling up vacancies on the walls: this, however, would have been far better done at the fall of the leaf. See that the drainage of the border is perfect. Stake all newly-planted trees, and mulch them whether in borders or in the open ground. Continue pruning and nailing in favourable weather, and as fast as the trees on the walls are completed, manure the borders and fork it in lightly. The quantity and quality of the manure must depend upon the crops to be taken from the borders. It is never advisable to plant very exhausting crops upon them, but I am aware that in many small gardens it can hardly be

avoided: however, it should be confined to the surface as much as possible.

STOVE.

Examine the various tubers and bulbs that are dormant, and see that they are in proper condition, neither suffering from wet nor mouldiness. The principal object at this season should be to keep the plants dormant.

GREENHOUSE AND CONSERVATORY.

See that the foliage of Camellias, Rhododendrons, Oranges, and similar plants are perfectly clean. The contrast produced by the fine large shining leaves of the Camellias with their various blossoms at this season especially enhances the enjoyment to be derived from them. The principal object during the present changeable weather should be to keep damp and mildew in check. Look after insects, especially mealy bug, which if neglected now will be more difficult to extirpate after the plants have commenced their spring growth, and put forth their young and tender leaves. When it is necessary to water the borders of the conservatory choose a fine morning for the purpose, and give sufficient to moisten the soil thoroughly, using lukewarm water; and to guard against damp exhalations for a few days afterwards it is advisable to apply a little fire heat with air, to produce a gentle circulation of the atmosphere, and to expel damp. The plants to be looked over carefully every morning, and every decayed leaf and faded flower to be removed. As soon as the beauty of any pot specimens is over remove them to suitable quarters elsewhere, and supply their places with others in full bloom.

FORCING-PIT.

Keep the temperature, with a moderate supply of moisture, by night at 60°, and let the maximum be 65°. Get in Roses, to keep up a supply. Anne Boleyn and other Pinks may now be successfully forced if they have been potted and prepared for that purpose in good season. Get in, also, Persian and common Lilacs, Azaleas, both the hardy and Chinese kinds, Lily of the Valley, Hyacinths, and other bulbs, *Acacia armata*, hardy and Nepal Rhododendrons, *Daphnes*, *Deutzias*, &c.

PITS AND FRAMES.

Let the stock of plants in these structures be freely exposed to air during fine weather so as to keep them hardy, and, consequently, less liable to suffer from confinement if a change of weather should render it necessary. Any of the stock from which cuttings are required should be removed to a light warm situation, first clearing off the old and adding a little fresh soil to the surface of the ball. As *Verbenas* are very liable to mildew when placed in heat at this season, the frequent use of sulphur will be necessary to keep it in check. W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

GENERAL routine of previous weeks. Wheeled dung and rubbish-heap on frosty mornings, giving over as soon as the barrow wheels began to lick in the least. Much useless work is often incurred from paying no attention to cleanliness at the rubbish or dung-heap. The ground will get soft there, even on frosty mornings, and the barrow wheels will carry the mark for a considerable distance on the hard ground, and all that would be avoided by sprinkling some long litter close to the barrow-fillers. Dug and trenched up ground on all crusty days, as the work can be done so much more cleanly and expeditiously than when the soil from being clammy, clings alike to spade, forks, and the shoes of the workmen. In kitchen garden trenched and ridged in the usual way, but in the flower-beds, though trenching and bringing up a little of the lower soil, we chiefly leave it at the bottom, and keep the surface to the surface, and what manure of rotten leaves we give, is also placed at and kept near the surface. Looked after slugs among Lettuces at the foot of walls, and Cauliflowers under glass and in beds; and though I have great faith in rough surfaces and ashes and lime-sprinkling, and all the rest of it, I always place most dependence on the "Weaver" remedy, "Catch them and kill them." Sowed the bed made up for Carrots. Gave plenty of air to *Asparagus*-bed, as it comes faster than we want it, and here is a point of a little nicety. We like it green before using it, and we like it crisp also, but if too much air is given in a rather cold day after it has been used to a fair degree of heat, it will be apt to eat harder than is desirable. The glass cannot be kept too clean for insuring

greenness, and in very severe weather when much light cannot be given, greenness may be obtained by keeping the stalks after being cut surrounded with damp moss at their base, and the bulk exposed to the light in a window or hothouse. Sowed near a furnace a few *Cucumber* seeds, and made up a bed of fermenting leaves to get them in by-and-by. The bed will be just now about 4 feet at back and 3 feet at front, and with leaves alone will do, we trust, for early plants. Transplanted Dwarf Kidney Beans in pots where there was a heat of about 50° to 55°, and sowed more as we shall be applying more heat presently, and nothing is more pleasant to eat than early Beans. We find they are now much more prized than when a supply was kept up all the winter. I am quite sure that the labourer enjoys his first dish in July as much as the nobleman does his at Christmas. Spawned and earthed up small Mushroom-bed, having mixed a good quantity of dry sods to get the material (the dung), into a good condition. Placed some of these sods and a little chopped straw with manure in a shed, in order to cause it to dry sufficiently without heating violently.

FRUIT GARDEN.

Kept pruning as opportunity offered, and preparing for fresh planting that could not be done in autumn. Scrubbed walls with brooms and brushes that are old and soft to get them in good order for whitewashing; for fruit trees began sprinkling Peach-house, now filled with bedding plants, but which will be all removed before the trees approach the blooming state; all the heat given now being just so much as is necessary to keep out frost. Gave early Strawberries that wanted it a little water. Now is a critical time; too much water will rot the flower-bud, too much dryness will shrivel it, and the happy medium must be aimed at. If there is the sign of a worm-heap, the gentleman must be dislodged at once; a little lime in the water will make him uncomfortable, and most likely bring him to the surface. Damped the stem of the Vines in small pit. Heat now about 55°, which just suits the Black Prince Strawberry. Cleared all the leaves off the Figs in Fig-pit, and every fruit bigger than a small Pea. Kept them bearing longer than we ought to have done, as, like most things, they are all the better for a rest. A vineyard that showed signs of thrips has just been cleared, the communications with another house securely closed, and a good smoking given to it with sulphur being burned in it along with a little sawdust: of course, such treatment will kill each and everything that is green, and should never be resorted to unless the wood is thoroughly hard and well ripened. Such fumes search into every hole and cranny; and, though we fear not successful in destroying eggs of insects thoroughly, it will make pretty sure work of all that are alive. Once, however, on opening a house, so treated in a morning, we found a robin alone in it, even though we found it hardly possible to breathe; he must have got in some snug corner. A pound of sulphur would fumigate a house—say 30 feet by 12 feet, and 10 feet in height, and might be mixed with a couple of pounds of dry sawdust so as to burn slowly. The drier the house is the better. A flower-pot, an old saucepan, or even an old shovel are very good for the operation, getting a few nice embers, placing a little paper and straw on them, then the mixture, and covering all over with moss.

Plants as last week.—R. F.

TO CORRESPONDENTS.

** We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the "Journal of Horticulture, &c."* 162, Fleet Street, London, E.C.

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

We cannot reply privately to any communication unless under very special circumstances.

MANGOLD WURTZEL WATER (*A Scabrier*).—So far as the water in which Mangold Wurtzel has been boiled from being poisonous, that we have drunk beer and wine made from it, the roots being sliced, boiled, and pressed to extract the entire juice.

MANURING PHILOXERAS (J. M.).—As your ground is very exhausted, there is no objection to mixing with it a little nightsoil, as it is the only manure you have; but we should rely upon watering with very weak liquid manure made from the house sewage, and applied in spring and summer.

HERBARIUM PLANTS (J. B.).—We know of no work devoted to the cultivation of herbaceous plants. We began publishing a series of papers intended to include all the species and their culture, but we found that they would occupy too much time and space. However, very shortly we shall commence an epitomised list of such plants, with much useful information about them.

WORMS IN SOIL ABOUT LANTHERIA ROSEA (L. G.).—Put a handful or two of quicklime into a pail of water, and let it stand all night, and water the soil with the clear liquid in the morning. Take away all worms that come to the surface. Place a little leaf mould on the surface, and cover with a board or slate. This will induce those worms to get into it, and next morning you may take all away, dressing and worms. If that does not repeat the dose. A few days afterwards push away what soil you can safely do with your fingers and a pointed stick, and replace with fresh peat and loam, which you have heated over a furnace to kill all worms and their eggs, and exposed to the air again before using.

ORNAMENTAL GREENHOUSES (L. W.).—We doubt if any will surpass your manner, quite as well as capsaicumstrum. Solanum jasminoides is a fine climber, but does not make much show with its fruit. S. melongena is the Egg Plant; white and purple varieties, which look well when well grown. S. muricatum produces pretty berry-like fruit. S. quense produces fruit called Queen of oranges, a skinning has pretty foliage, and produces what is called the Kangaroo Apple. S. citrullifolium might also answer your purpose; but these will show their fruit chiefly in autumn and summer, and will not keep in winter unless in a good temperature. We think a good variety of Capsicums, large, small, cherry-shaped, would suit your use, and have various colours.

KIDD'S SYSTEM OF HEATING (An Old Subscriber).—We can only refer you to what has already appeared in our pages on the subject. Kidd's system has not yet been applied to stove plants as far as we know; therefore we have no experience on that branch of it.

OCCEARD IN A GRASS FIELD (B.).—The grass should be dug up round each tree, and the surface of the soil kept cleared of grass and weeds, in a circle 6 feet in diameter. We refer to your asking this question that you have merely cut holes and stuck in the trees. Trees will not flourish unless a wide space around them is trenched and made loose to enable the roots to penetrate it freely.

VARIOUS (H. Elliott).—You were quite right in sending your letter direct to our office. We wish for practical papers, for we are overwhelmed with sentimental effusions, and are obliged to reject them all. That the Potato disease is connected in some way with atmospheric electricity has been repeatedly suggested; but the suggestors have never been able to get over the difficulty that electricity has always been in the atmosphere, yet the disease is of recent occurrence.

POULTRY DENG FOWLS (Subscriber).—It is a very powerful manure, and must be applied sparingly, unless the soil is poor, and not until the spring after the blossom-buds are discernible.

LEAF MOULD (E. A., Birmingham).—This from a coppee, if not mixed with tenacious soil, will be as good for potting purposes as leaf mould from any other source. Neither lime nor salt must be mixed with it for pot soil.

ASPECT FOR GROUND VINEY (Muscat).—It is best for it to stand north-east and south-west, but north-west and south-east are nearly as good points.

EXCLUDING HARES AND RABBITS (H. W.).—There is nothing so good for securing hares and rabbits as trapping and shooting them, and making them uncomfortable. All appearances of holes should be smeared with tar—in fact, were the whole of the wire fence daubed with a tar brush at the bottom it would keep them aloof. A two-foot wire fence is not sufficient. We had such a fence, and they, especially hares, popped over it quite comfortably. This two-foot was fastened to a five-foot fence. The iron bars above the wire fence were 8 inches apart. We took a strained wire between the two bars, one immediately above the net, and since then we have been little troubled. A number got stumped being caught by the wire as they attempted to jump. The four-inch space above the wire-net and this longitudinal wire might have let them through, but they never attempted it.

GROWING VINES AND FIGS TOGETHER (Idea).—To secure a crop of Grapes and Figs next season from plants now strong, the best plan will be to buy the plants in the pots, and pot-dress them well, and not repeat at all. If you must do the latter, break the balls a little, use the smallest soil possible, and cram in the earth round the ball very firm. To make sure of such rods we would not shorten them much, but thin out more than half of the smaller buds. This, of course, is for getting fruit. Were we planting such for permanent plants in a viney, we would cut down to a few buds.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

ORIGINATOR OF PRIZES FOR POULTRY.

OUR poultry show has become an established fact, and this has given rise to a wish to know, through the medium of your Journal, who the individual was that first offered a prize for poultry, as most assuredly he deserves the thanks of the fancy from the great good it has achieved.

I know several working men in this neighbourhood who, through their skill and care in breeding, &c., have made very substantial benefits from it; so much so, that their daily labour has become quite a secondary consideration with them.

In September last the Keighley Agricultural Society held its nineteenth anniversary, and it proved a great success, considering its beginnings. The poultry show one of its great attractions. Now, nineteen years ago we began with a poultry show exclusively; the year after we added pigs, and so on. The gen-

tleman that first offered a prize for poultry at this Show was J. G. Sugden, Esq., then of Stretton Hall, now of Eastwood House, Keighley, and his intimate friends said of him at the time that he had taken leave of his senses; was not fit to be at large; and so on; and that it would never succeed, and laughed at the idea. But that the suggestion has overcome ignorance and opposition, we have only to refer to Birmingham, the Crystal Palace, &c.

Now, my query is, Do you know, or can you refer to any prize being offered for poultry previous to the year 1812? If so, I would thank you to say where and by whom, as it would settle a dispute in this neighbourhood, and would be to the poultry fancy an interesting fact.—W. BOYNE, Eastwood House.

[We have records of cock-fights now in our possession more than a century old. The question we have to ask ourselves is whether a fight is a show. If it is, then some of the Africans are much older in the pursuit than we are. We were told by the late General Wemyss that when in military command, he always sent an armed force where there was a cock-fight. It was an old tradition that a man would back his favourite bird by betting his children, his wife, his hut, and at last his own liberty. When several of them thus found themselves slaves, they were apt to be quarrelsome, and the armed force was necessary. In those countries no man can recollect the origin of cock-fighting. As many of our readers will not, perhaps, care to be identified with the pursuit viewed pugnaously, we will look upon it in its modern and legal light as an exhibition for symmetry of shape and beauty of feather.

The fowls that have been exhibited many years ago are the Moonies and Mosses in Lancashire and Yorkshire, and the Sebright Bantams in and near London. Thirty years ago these latter were shown by Sir John Sebright, Mr. Hollingworth, Mr. Prentice, and others; and since, but before 1812, by Mr. Leigh and others. The points and weights were decided; the latter was 17 ozs. for the cock, and 14 ozs. for the hen. A cock was sold in the early days of these shows for £25. High-class Toy Pigeons were often shown at these meetings; but they were strictly private, and, therefore, little was heard of them. The first poultry shows we know of were held at the Zoological Gardens, Regent's Park. The prizes were very liberal, and the entries were satisfactory, many coming from Ireland; but it was found too troublesome for a prosperous Society. The next prizes we knew of were two given annually by the Earl of Verulam, at the Herefordshire Agricultural Meeting, for the best two pens of Dorkings that could be produced. We recollect no others till shows became a regular institution.

We have heard of meetings many years ago at private houses, where numbers of gentlemen each brought a bird, and these were put on the table in rotation, and judged according to the rules admitted by every exhibitor to be correct—each one decreed his neighbour's bird, and lauded his own. One great good that resulted from these meetings was that amateurs exchanged birds for a season for breeding purposes, and that they carefully communicated to each other anything that could advance their common pursuit.]

CREVE CŒUR, ANCONAS, AND CHAMOIS FOWLS—COOKING COCHIN-CHINAS.

In your report of the "extra class" of the Birmingham Show, you mention Crève Cœurs, Anconas, Chamois, and Cuckoos. Now, will you kindly give a description of these fowls, and say if any of them have such sufficient merit that it is likely they will form classes for themselves?

The Crève Cœurs, judging from the description of them, are likely to prove a useful variety; but I hope that Mrs. Blair's description of this fowl is more correct than that she gives of the Hamburghs, which is really absurd, as she says, speaking of Pencilled and Spangled, "all Hamburghs should have clear necks."

Can anything be done with Cochins after they get past a year old, in the way of cooking? I am unjust in this difficulty. I keep a few Cochins. Suppose I want to sell any—say over a year old, I can only do so to a poulterer, for, perhaps, is, each, perhaps not so much, and if there is any way of making them eatable, they must be worth a good deal more. This is a great object to fanciers (like myself) of small means, and any information would be conferring a great boon on them.—W. C.

[The only birds among those you name that are likely to form

a class are the Cive Coeurs. The Anconas are very seldom seen, and very little admired. They are birds with small bodies, black and white patchy plumage, enormously large combs and gills, resting on the ground when they eat. They are said to be very good layers. The Chamois are Buff Polands, and sprightly, good-looking birds. Their buff feathers are often faintly edged with white. The Cuckoos are birds of any breed; but Cuckoos in colour—that is, blue, slate-coloured, barred plumage all over. We have had Chesko Dorkings, Cochins, and Bantams.

Your Cochins of any age are capable of supplying an excellent meal, or a very choice dish. It is only so long as the idea of cooking is confined to roasting and boiling that old fowls are useless. They may make potted meat, or a most excellent and savoury pie. Every one knows how to make the former, we will give directions for the latter as briefly as possible. Get an earthen vessel of any kind having an earthen lid with a small air-hole, line it all round with slices of bread. Having cut your old Cocker up in pieces, and having collected all the scraps the house affords, a knuckle and some odd pieces of ham, or the lean of some bacon, a dry knuckle and some unmixing scraps of a shoulder of mutton, some stock meat, and a little breast of veal or mutton, take them and go to work, either figuring to yourself a Chinese puzzle, or an old marble chimney-piece, and make layers of the meat, continuing till the vessel is full. Fill in with broth, or gravy if you have it; failing that with water. The only difference is, the former makes it rather better. Put on the lid, fasten it down by tying with a piece of string, and place it in a slack oven all night. It will simmer and simmer until all the meat is as tender as butter, and all the water will be turned into jelly. The pie itself will be a sort of mosaic, and the odd scraps that looked anything but tempting when they were put in, will now come out set in jelly, and be as good to the palate as to the eye. But if your cock has a weakness for that abomination of all cookery, a good boil, you must not expect the success we have promised.]

COLOUR OF A PILE GAME COCK'S LEGS.

WHAT should be the colour, or the most desirable colour, in the legs of a Pile Game cock? Would dark blue legs in an otherwise good bird prevent his taking a prize? The bird weighs little short of 8 lbs. Is that a good weight for a Game cock?—MEDICUS.

[We always fancy that for a Black Red Game fowl the best coloured leg is a willow. It is but a fancy, as we have frequently answered the query in this paper, that any colour is not only admissible but correct. There is only one rule of colour, and that is, that all the fowls composing a pen shall have legs of the same hue. It is as true of a Pile as of any other colour, but we think a yellow leg looks well on a light Pile. Blue is quite as correct. Eight pounds is an unusual weight for a Game cock. They do not average 6½ lbs.]

WHITEHAVEN POULTRY EXHIBITION.

On visiting this Exhibition we were much pleased to find so excellent a collection of poultry had been got together so far north as Whitehaven.

The great expense of transit from the southern or even the midland counties of England acted as a prohibition to poultry competing from those important districts; but even with this great drawback to the entries numerically considered, it was somewhat a surprise to find that the immediate locality was represented by a considerable number of pens that would be well able to hold their own at most of our principal meetings. The Committee were evidently a body of gentlemen most anxious to do justice, and act with unvarying courtesy to every one; but the management of a poultry exhibition appeared a somewhat new task to most of them, and we have little doubt the experience gained at the just-concluded Show, will prove of great value to them on future occasions. One of the principal errors in the arrangements that met our eye at the first glance was, permitting exhibitors (and not a few absolute strangers al-*o*), to enter the exhibition-room prior to the poultry being judged at all, and these parties thus taking advantage of coming before their own and their opponents' positions. This feature is quite erroneous good nature on the part of the Committee, and might

possibly give rise to many unpleasanties, independently of the injury that it must of necessity afterwards cause to the admission funds, for we heard not a few express themselves as "having seen all they wanted to see for nothing." All birds should be received at the doors by persons appointed to that duty; and none others, whatever their pretence for so doing, should be allowed an entrance. The birds were well cared for, and the Refuge School Rooms afford good convenience for a small collection, though if the light could have been more universally diffused throughout the pens it would have been a great improvement. The additional gaslights put up for the occasion caused a rather increased obscurity to the lower pens.

The Game fowls were, perhaps, the best classes in the show-room, and there is but little doubt the Brown Reds were the most perfect in condition of any. The winner of the silver cup was of this colour, and it is not frequently a better is met with. We were much pleased also with Mr. Robinson's prize pen of chickens, they were a great credit to Ulverston breeding. In the old birds the same gentleman exhibited a first-rate cock, but mated to a hen with a comb that would disqualify anywhere. Many of the Game fowls, too, did not match in the colour of the legs—always a fatal objection to success. The Duckwing Game were quite a feature, the first-prize pen excepted. The Spanish class throughout showed the locality did not suit them, their condition was decidedly inferior both as regards general health and plumage. The Dorkings, contrariwise, were good. In the Cochins, the Partridge-coloured richly deserve very favourable mention. The Golden-spangled Hamburgs were, undoubtedly, one of the very best classes in the collection. Mr. Jones, of Parton, however, took a sweep of the prizes against a great competition. The other varieties of Hamburgs did not muster so well. Not a single pen of Polands was entered. In Bantams, the Game, Gold-laced, and some excellent Japanese were well shown.

We hardly expected much in Aylesbury Ducks, and our surmise proved correct, but the Rouens were really good.

The collection of Pigeons was capital. We can barely call to mind better specimens than the successful Red Tumblers, White Owls, Runts, Barbs, Jacobins, Turbits, or Nuns. Unhappily the weather proved most unpropitious from continuous rain, though even under this disadvantage there was a tolerable attendance.

GAME (Black-breasted and other Reds).—First, H. Miers, Whitehaven. Second, J. Brough, Carlisle. Highly Commended, R. J. Robinson, The Nook, Ulverston.

GAME (Duckwing and other Greys and Blues).—First, R. J. Robinson, Ulverston. (Secondly, *ibid*.)

GAME (any other variety).—First, G. C. Whitwell, Kendal. Second, J. Doney, Aspatia.

SPANISH.—First, I. G. Parke, Moreby. Second, P. Mackay, Moreby. Commended, J. Brown, Aspatia; R. J. Robinson, Ulverston.

DORKINGS (Coloured).—First, E. Topping, Southth. Second, T. Dixon, Rheda. Highly Commended, T. Dixon, Commended, J. Doney, Aspatia; E. Topping; J. Brown, Aspatia.

COCHIN-CHINA (any variety).—First and Second, E. A. Agliony, Wigton Hall.

HAMBURG (Golden-spangled).—First and Second, W. G. R. Jones, Parton. Commended, W. B. Clark, Whitehaven; J. Webster, St. Bees.

HAMBURG (Silver-spangled).—Second, A. Thompson, Hensingham. (First withheld.)

HAMBURG (any other variety).—First, J. Webster, St. Bees. Second, E. A. Agliony, Wigton Hall.

GAME BANTAMS.—First, I. G. Parke, Moreby. Second, R. J. Robinson, Ulverston. Highly Commended, R. J. Robinson. Commended, I. G. Parke.

BANTAMS (Gold or Silver-laced).—First, I. G. Parke, Moreby. Second, R. J. Robinson, Ulverston. Commended, J. Brown, Aspatia.

BANTAMS (any other variety).—First, Second, Miss King, Moreby. Highly Commended, J. Newby, Manchester Head; J. B. Wilson.

DUCKS (Aylesbury).—First, M. Irwin, Whitehaven. Second, I. G. Parke, Moreby.

DUCKS (Rouen).—First, J. Towerson, Whitehaven. Second, E. Weston, Bootle. Highly Commended, W. G. R. Jones, Parton.

DUCKS (any other variety).—First, J. Towerson, Whitehaven.

POLANDS (Coloured).—First, J. & W. Towerson, Egremont. Second, H. Miers, jun., Whi chaven. Tumblers (Almond).—Fritz, R. Pickering, Tumblers (Baltimore).—First, S. Sherwin, Whitehaven. Second, H. Miers, jun. Tumblers (any other variety).—First, R. Pickering, Carlisle.

Second, J. & W. Towerson. Peafowls.—First, R. Pickering. Second, J. Weeks, Fantails.—First, A. G. Brooke, St. Bees. Second, R. Pickering, Jacobins.—First, A. G. Brooke, St. Bees. Second, R. Pickering, Commended, J. Weeks, Bootle. Trumpeters.—First, M. Irwin, Whitehaven.

Second, S. Sherwin, Whitehaven. Barbs.—First and Second, M. Irwin. Highly Commended, M. Irwin. Commended, H. Pickering. Second, M. Irwin. First, R. Pickering. Second, M. Irwin. Highly Commended, J. & W. Towerson, Egremont. Ouzes.—First, J. & W. Towerson. Second, S. Sherwin, Whitehaven. Any pens *to be specified before*.—First, M. Irwin. Second, A. G. Brooke. Highly Commended, A. G. Brooke.

BARBS (up-laced).—Fritz, R. T. Cheyney.

GAME COCKS.—Silver Cup, A. G. Brooke, St. Bees. Second, R. J. Robinson, Ulverston. Thru, J. Brough, Carlisle. Big leg Commended, R. Bell, Whitehaven; J. Brough. Commended, W. Lyon, Parton. Cockerels.—First, R. J.

Robinson. Second, G. C. White-D. Kendall. Third, R. Cousins, Irish Street, Highy Comynedel, M. Alsop, Wutchaven. Commended, Mrs. Parker, Coalstath, Brampton; J. Bleakinsopp, Onzatersle.

DORKING COCKEREL.—Winner of Sweepstake, J. Brown, Aspitry. Highly Commended, J. Deane, Aspitry; E. Tomlin, Sadeith, Lane End.

TURKEYS.—Winner of Sweepstake, E. Weston, Hoarce. Commended, I. G. Parke, Moresby.

GOLDENBUCK.—Winner of Sweepstake, D. Bowness, Frizington.

CANARIES.

Yellow Belgian.—First and Second, R. Bell, W. Aelhaven. **Buff Belgian.**—First and Second, R. Bell. **Yellow Males.**—First, J. Armstrong, Bridge Street, Canisls. Second, H. Richardson, Arleford. **Buff Males.**—First, J. Armstrong. Second, H. Richardson. **Reddell (Yellow or Buff).**—First, J. Armstrong. Second, H. Richardson. **Lizards (Gold or Silver-spangled).**—First and Second, R. Bell.

Mr. Edward Hewitt, of Eden Cottage, Sparkbrook, officiated as the Judge.

CROSS-BREDS BETWEEN SILVER PENCILLED HAMBURGH AND SPANISH FOWLS.

“WORCESTER’S” statement in a recent Number brings to my mind an occurrence of two or three years ago, of which I made a men. at the time. I was making experiments upon different crosses, and amongst others raised two good broods of chickens from two Silver-pencilled hens and a Spanish cock. These fowls were evidently of a grammatical turn of mind, and wishing to show practically that two negatives make a positive, seven out of eight pullets showed a perfect obstinacy in sitting, and several of them were allowed to rear chickens, and conducted themselves admirably as mothers. There could be no other cross-breeding, as I had no other cock at the time. All these half-bred fowls were black, the cocks with golden and the hens with brownish hackles; both had most extravagant double combs. The eggs were nearly as large as those of the Spanish, but not nearly so abundant as those from the Silver-pencilled. I could see no advantage in this cross.

One of the best fowls for table is, I think, the first cross between the Dorking hen and the Game cock.—NESTOR, *Malvern*.

NORFOLK AND CAMBRIDGESHIRE TURKEYS.

I WISH to commence keeping Turkeys, and should wish to start with the right sort. The Norfolk Turkeys are strongly recommended to me as being the best. I am told by some that the real black are the true Norfolk breed, and by others that they are not. The black ones I find are invariably smaller than the somewhat grey-coloured ones. I thought of buying three hens and one cock bird. I do not want them for exhibition, but for table.—E. W. A. G.

[The Norfolk Turkeys are quite black, and they are not as large as the Cambridgeshire. It has been with them as it will be with all poultry—wherever feather and colour are made a *sine qua non*, other, and in our opinion more valuable, properties must be sacrificed. You can start very well with a cock and three hens.]

THE FATTENING OF RABBITS.

In reply to “A Novice” we insert the following:—

Many ways of fattening Rabbits have been recommended. Nothing answers better than barleymeal, oatmeal, or split peas, or a mixture of these substances, by adding now and then a little tender hay and one or two spoonfuls of water a-day for each Rabbit. The best age at which you can take Rabbits to fatten them is at five or six months; having reached that age they fatten on little, while before that age they could not fatten, they have nothing but skin on their bones in consequence of their growth. The bony system is developed with the cutaneous system at the expense of the other organic systems; and that is the reason why little Rabbits have generally larger stomachs than those of six or seven months. One should not wonder to see them get thin when they are young; one should rather be uneasy if they grew fat, it being an unnatural state, and you would soon see them die of diarrhoea.

Rabbits should be kept at all times in clean dry habitations, and you must pay particular attention to those you fatten. Although much exercise is not good for them at this time, if they were placed for an hour a-day in fine weather on a rich

ground, or on a gravelled walk, and given a few vegetables to eat, it would greatly contribute to their health and thriving.

These animals pay in flesh for what they consume; when they have attained five or six months they have generally gained 3 lbs. in four days, and sometimes 9 lbs. in ten days. The older they grow the more flesh, fat, fur, and skin they acquire.

A young Rabbit is not only without much flesh at three or four months, but the flesh is also without taste; at six months its flesh is more firm and better. The older it grows the less tender its flesh becomes; a fortnight is sufficient to make it fat and fit for eating. The young males should be killed before the young females; they become amorous sooner, and their flesh always loses some of its quality.

DUMFRIES AND MAXWELLTOWN ORNITHOLOGICAL SOCIETY.

THE third annual exhibition and competition of Canaries, Poultry, and Pigeons, under the auspices of this Society, took place in the Market Hall, on the 1st and 2nd inst. The Show was open to all Scotland, and, from various causes, was by far the most successful that has yet been held in connection with the Society. No fewer than four silver medals presented by supporters of the Society were offered as prizes, and the Committee having exerted themselves to obtain some standing for the Show as an exhibition of poultry, the result was a display in that department, which, for quality, has never been equalled in the south of Scotland, while the entries were unexpectedly numerous. Of Poultry, 95 pairs were exhibited; of Canaries, 217 cages; and of Pigeons, 28 cages. The poultry coops were ranged in the centre of the Hall; the bird cages round the walls. The Hall resounded, inside and out, with the shrill crowing of cocks and twittering of Canaries, though the incessant noise from the defiant lugs of Chanticleer fairly drowned the cheerful concert of the warbling songsters. But the Show altogether was a most interesting and beautiful one. The exhibition of birds was very much more numerous than any previously held in Dumfries, and the quality better and more equal—the Judges having in most cases some difficulty in coming to their decisions. It would be invidious to particularise where all was good and worthy of the Exhibition; but, undoubtedly, the “King” of the Show in the Canary department was the yellow pied-bill cock of Mr. Coupland, Dumfries, the winner of Mr. Gibson’s silver medal. This bird is of extremely elegant shape, and is valued at £50. His cage was hung with silver medals: he has taken the first prize at a Show in Glasgow, and won the medal at Moffat last year; he also took the first prize at the Lockerby Show; he took the first prize and prize medal at the Dumfries Show last year, and has been equally successful this year. This little paragon attracted many admirers. Among the specimens sent for decoration—that is, not for competition, were two large cages of Canaries shown by Mr. McGregor, confectioner, and Mr. Wm. Cowan, Dumfries—the one containing seventeen and the other fourteen birds; also a cage of three Crossbills, belonging to Mr. J. Maxwell, Hillend Mill. These droll but rather clumsy-like creatures were got in Dalswinton wood; they are said to be very numerous about Moffat. Their grotesque movements, incessant motion, and peculiarly shaped bills so well adapted for splitting open at a stroke the fir cones on which they feed, attracted much notice. One of them was evidently flattered by the attention he excited, and perseveringly occupied himself in describing an endless series of somersaults.

Perhaps the greatest attraction in the department of decoration was the large case of the eggs of British and foreign birds, shown by that enthusiastic collector of all kinds of curiosities, Mr. W. G. Gibson, bookseller, Dumfries. This case is only part of Mr. Gibson’s collection of eggs, yet it contains 400 distinct varieties, from the minute egg of the Golden-crested Wren to the huge bulk of that of the Ostrich. All the varieties are labelled, are in a fine state of preservation, and arranged with the utmost taste.

In the Poultry department, many of the specimens exhibited were of first-class merit. The *Cochin-China* fowls shown by Mr. Biggar, of Maryholm, were unrivalled for size, symmetry, and beauty of plumage. The prize Game cock, the winner of Dr. Griev’s medal, belonging to Mr. James Thorpe, was a model of its kind. Mr. John Pagan, Clarendfield, showed a cock and hen of the Black *Malay* breed, which were universally

acknowledged to be truly magnificent specimens. The male bird is of remarkable size, and has quite a regal air, the effect of which is greatly increased by the long and slender arched tail, which is supposed to indicate some departure from the pure Malay breed. The plumage of these birds has a metallic lustre of peculiar beauty. In the same class, the Golden and Silver *Poldans*, shown by Mr. W. G. Gibson, were much admired. Among the Poultry shown for decoration were a splendid pair of African hens, belonging to Mr. Bigger, of Maryholm, and a pair of Japanese fowls belonging to Mr. Brown, Nith House.

A show of *Pigeons* was very good; the prize Fantails belonging to Mr. Kirkpatrick, Duncevo, being perfect beauties in their way. The Hall was on both days continually crowded with visitors, who appeared, from their minute examination and criticism, to enjoy the opportunity afforded them of improving their practical acquaintance with natural history.

A difficulty arose out of the Judges' award for the best Game cock, it being alleged that the bird shown by Mr. Thorpe, and to which Dr. Grieve's silver medal was adjudged, was the property of one of the Judges, though entered in Mr. Thorpe's name. The Committee are making inquiry into the matter.—(*Dumfries Courier*.)

IRREGULAR PRODUCTION OF DRONES.

I have taken considerable interest in the discussion respecting drone-breeding queens, and have had one this autumn which has somewhat resembled those described, and yet differs from them. The circumstances of the case are these: As formerly stated, I used every endeavour to increase my *Ligurians* by swarming, and had one natural swarm in August, probably near the middle of the month; and the young queen left in the parent hive seemed sterile for about two weeks afterwards. However, I then discovered that she had become fertile. In about fourteen days time I ascertained that the brood were entirely drones, both in the ordinary cells and also in the large cells; and feeling somewhat interested in the result, I paid particular attention to them on emerging from the cell, and could distinguish no difference in their appearance from the ordinary drones. I may also mention that, although they got pretty numerous, the bees did not molest them for several weeks, and I began to think that they must have lost their queen. However, on examination I very soon observed her majesty in a very healthy-looking condition, and also found her to be a very light fine marked *Ligurian*; and as I had no other *Ligurian* queen to replace her with, I allowed her to remain where she was; and the result justifies the action, for in due time I began to observe a number of young workers making their appearance along with their larger neighbours, until the scene became quite changed—nearly all young workers with an occasional male. And at the present time I find they are still breeding young bees; but a drone now and then makes its appearance, and I send you one as a specimen, which I caught coming out of the hive this morning (Dec. 15th), evidently for the purpose of taking its first flight. You will perceive that it is not so well marked as the *Ligurian* drones generally are, and I believe it is much darker than most of those which have been bred by this young queen. However, I have thought better to send it, as the season is now far advanced; and if cold weather should set in I may not have an opportunity of getting another, as they are now scarce. You will perceive that I have merely stated the facts of the case without offering any comment on it. However, it clearly shows that a young queen may first produce only drones and afterwards become a fertile breeder of working bees. If it had not been that there were drones in this hive at the time the queen was reared, I would have considered the occurrence as a provision in Nature to supply that want; but as this was not the case it seems rather unaccountable why it should have occurred. Am I right in supposing that any instance of drone-breeding queens that has come under your notice have never been known to breed anything but them. I should like to have your opinion of this case after examining the specimen sent.—J. S.

[I believe I have a similar case in my apiary, but cannot be sure until mild weather affords better opportunity for examination. I have never kept a true drone-breeding queen for any great length of time, but have no doubt that one of this description would breed nothing but drones during the whole of her life.—A DEVONSHIRE BEE-KEEPER.]

DOES A QUEEN BEE STING OR BITE?—EFFECTS OF INTERBREEDING.

I FANCY "UPWARDS AND ONWARDS" makes a mistake in page 268, and that he took a sharp pinch from the mandibles of the queen bee he was handling for the application of her sting. At any rate, he does not say that she left that weapon behind, which she could scarcely have failed to do if she had darted it into the cuticle of either his thumb or forefinger. The reluctance of the queen bee to use her sting is certainly most remarkable. I must have handled many scores, and never was stung by any. She is, however, by no means so particular about using her jaws, and will bite pretty sharply if provoked to do so by rough usage.

I am also tempted to inquire if he is sure that the bees he speaks of, in the cottager's garden, have really never been crossed, but have "bred in-and-in for years." If this be indeed the case, they must be separated by a distance of several miles from any other bees, since I have proved, and stated in page 39, that drone influence extends fully two miles.

May it not, however, be open to a doubt whether bees do deteriorate, as a home imagined, by being bred in-and-in? I once saw an apiary of nearly forty stocks (and which had numbered as many as eighty), all resulting from a single swarm brought from a distance many years before. Now, this apiary was attached to a lone farmhouse, probably quite as much, and possibly even more, isolated from other bees as the cottager's garden mentioned by "UPWARDS AND ONWARDS," and no signs of deterioration of the species were to be detected.

I would also refer to pages 221 and 222 of the XXIV. Vol. of THE COTTAGE GARDENER, wherein are related the circumstances under which all the bees in Tasmania originally sprung from a single stock. This must, of course, have been a case of undoubted interbreeding without the possibility of its effects being ameliorated by a single cross; and yet, I may confidently appeal to the experience of a no less accurate observer than "E. & W." to state whether I am not correct in asserting that the honey bee of Tasmania is not one whit inferior to its European progenitor. Taking these circumstances into consideration, I believe that "UPWARDS AND ONWARDS" may dismiss the notion that his neighbour's bees have deteriorated by breeding in-and-in, and may fairly place to the credit of his superior management, any difference in favour of his own bees which he may detect between them and others of their species which may happen to be in charge of a less skilful apiarist.—A DEVONSHIRE BEE-KEEPER.

P.S.—I cannot agree with what is stated at the end of "UPWARDS AND ONWARDS" article in page 258, since I have often found swarms which failed to fill their hives the first summer form the strongest stocks in the next.

THE SUPER-POSING DIFFICULTY.

WHEN two such leading contributors as your Devon and Renfrewshire correspondents got completely at variance on a point, not theoretical but altogether practical, it was no wonder that we, the minor on-lookers, should be fairly nonplussed; and it must, therefore, have afforded your apiarist readers much pleasure perusing "E. & W.'s" very satisfactory solution of the difficulty.

"E. & W.'s" remarks are capital, except an unfortunate oversight towards the end, where he says, "I should give to 'A. W.' this better advice—to follow the northern plan if he wishes his bees to take possession of the upper hive? Why if? Surely your correspondent cannot overlook the fact that to get the bees to ascend was the gist of 'A. W.'s" query, and his only motive in uniting his hives, and on which all the dispute hangs. He need not, therefore, apologetically allude to his siding with "A. RENFREWSHIRE BEE-KEEPER," as his mode of reasoning altogether tends to confirm the opinion expressed by that apiarist, more particularly as "A. W." told us at page 410, last volume, that he employs bars and slides. Should that be the case with his lower hive under discussion, from my own experience in uniting these hives, which I have done over and over again with the exact results described by your Renfrew correspondent, I can therefore most unhesitatingly endorse all he has said. Such storied hives, be they two or many, invariably become one when united, and it is an unquestionable fact that bees winter at the top.

On the other hand, should this particular lower hive have a

preponderance of honey in it, and only these small conical openings in the top we sometimes see, which very possibly your Deron correspondent had in his mind's eye when he wrote, I should be prone to entertain the idea, in such a case, the lower would become the stock; but I never made the experiment.

Were there a large central three or four-inch aperture, the probability of their ascending would be enhanced from the bees generally congregating more between the middle combs.

I ascribe this diversity of opinion on "A. W.'s" case to the principles and practice of storiying not being so well understood in the south. The high system of farming practised in many districts in the north tells most unfavourably against the bee-keeper, forcing him to tax his ingenuity to combat this, the unfavourable climate and short season, by combining his swarms on the storiying plan to effect the same result, that in many localities in the south the most negligent bee-keeper easily can with single swarms and no trouble. The hint of your great contemporary, of Printing House Square, at the Cattle Show dinner the other day, as to the advantage his southern hearers might derive from acquiring a knowledge of the Scotch system being equally applicable to apiculture as agriculture.—H. B. D.

HOW I BECAME AN OXFORDSHIRE BEE-KEEPER.

(Continued from page 288.)

WHEN the combs are extracted, place four of the small wedges equidistant around the bee-board, where the circumference of propolis points out, and replace the hive upon them; the wedges will prevent crushing the bees, and leave an opening around for the natural possessors to return and gorge themselves, and for their neighbours also to come and assist at the feast, to clear out the hive from every, the least, particle of honey, and no Dutch housewife could perform a cleaner sweep than the bees make of it in that respect; though, poor little things, after they have been robbed of everything, I invariably find they have begun forming new combs, and elongated some an inch or so in several places before nightfall, thus setting us the example that after misfortunes the most wise plan is to tie on our aprons and go to work.

Now, take the dish or dishes of honeycomb away a hundred yards, the further the better, as the case may be; place them on a greensward if possible, near to some outhouse or room where there is a door which can be closed, and within which another empty dish or pan is placed. Lift a corner of the cloth from the dish containing the combs; raise each separately, and brush off any stragglers or those plastered with honey on to the grass, where their namesakes will soon clear it from off them. Take each comb, after having done so under cover, and close the door upon it; thus the bees are kept from intruding on one's after-operations, the first of which must be to minutely examine the combs, for centrally in them bee-grubs more or less will be found, which, if no notice were taken of them, hundreds of bees would be lost to the colony. So I brought forth a fig-drum, one of those mentioned before which had been denuded of its contents, and cut away the comb in sections containing the brood so as to fit into it, and press firmly against the sides, that on reversing the super they will maintain their position similarly to what they would had the bees attached them there naturally. I then placed it over age 2, just in the same way as if I was adjusting it for honey working in the spring, and the bees will hatch out every grub and make ready the super for next year, by clearing off the remains of honey adhering to its interior. I thus killed two birds with one stone, got the grubs brought to maturity, and the supers beautifully cleaned. The bees will unite the temporary combs to the sides of the super after their own fashion, but of course they will be cut out again to become melted into wax anon.

Now the seals from the surface of the cells, containing the honey, should at once be flayed off with the thin worn carving knife, and be placed in canvass bags; the pure combs cut and sorted into one, and those pieces containing bee-bread put into another, to be then suspended over basins to drain off the honey or, should the weather prove cold or the honey soon thicken, as it has done this season, suspend the bags somehow near the warmth of the fire, in order to relieve the honey more expeditiously from the combs. Under these latter circumstances, I place my honey in a tin forced suspended to a bottle-jack, similar to roasting meat. Though I am careful to prevent it from

becoming so hot as to melt the wax, and every now and then I work the bags about with my hands to alter the position of the combs; but I am careful so to squeeze as not to crush them more than necessary. Happening to have them by me, I have stored my run-honey this year in wide-mouthed bottles, similar to those which are used for preserving green gooseberries, and when it becomes congealed by the cold I shall gently warm the bottles to cause it to run out again when wanted. In the afternoon I took the pan, &c., off from age 1, and loosened the hive from its propolis and the board, and, in the dusk of the evening, spread a cloth on the ground by its side, laid two sticks upon it, placed age 6 upon them, dashed out the bees, and immediately lifted age 1 over them, then winged the bees from the two boards on to the cloth, suspended a pan upon tressels over the hive, and left them roaring out their differences and to settle the affair amongst themselves in the best manner they could.

Why I place the pan upon tressels suspended over the hive is this: When the pan (perhaps I ought to mention that it is now brought into play to ward off treacherous storms whilst one is a-bed and asleep), rests upon the hive, a sensation is created throughout in taking it off, and the bees immediately begin to rush from beneath to find out what is the matter; and be as quick as one will, it takes a degree of time before one can release the pan from one's hands to lift the hive on to its stand, by which time the bees are become thick on the bottom of the hive, and numbers of them would become crushed upon the board, for it will not do to place wedges in this instance, as neighbourly visiting must certainly now be dispensed with. The pan and the tressels can be quietly removed without the bees gaining the least inkling, and their hive is caught up and placed upon the board quick as thought, so as not to endanger one of their lives.

I arose at five o'clock next morning, and placed the hive and united colony upon its pedestal in the manner just described, when I counted about one hundred dead combatants upon the cloth, but no queen was to be found amongst them. I espied her cast out dead from the hive on the morning of the next day. No fighting took place after the bees were placed on their stand. Previously, on the 2nd inst., I cut out the combs and united the two previously united casts of the 20th and 26th of July, to age 1, as I previously said I should; but instead of the 20 lbs. of honey which I anticipated, I had 10 lbs. only, owing to the wet and unfavourable time we experienced during July; therefore, my honey produce this year is 40 lbs., of run honey, and 37½ lbs. of first quality honeycomb in supers, 87½ lbs. in all. There was a considerable quantity of bee-brood in the combs of this hive, which I adjusted in a Payne's straw super and placed on age 1, when the pollen-carriers soon gave me to understand what they were intent upon. I could, and I did intend to take age 3, which would now produce me 40 lbs. more of honey; but it is so strong and vigorous, and considering that next season, according to reasonable anticipation, is likely to produce a good scyanore blossom, I shall do as the ladies are allowed to do—change my mind on account of the better prospect.—UPWARDS AND ONWARDS.

(To be continued.)

DESTRUCTION OF SMALL BIRDS.

THE following paper was read by Mr. Martin, sen., Reigate to the Reigate Natural History Club:—

The French are great eaters of bread; the supply and the price of that article of diet are, therefore, of great importance to the whole population of the country. The people of Paris itself, it is well known, are especially favoured at the expense of the rest of France, notwithstanding which, at the present moment, there is much grumbling amongst them.

Their consumption of animal food is much less than in England; and beef and mutton being dear, there is a destruction of small birds constantly going on, which they cook so as to make the most of them for the table. They are not only shot, but caught and trapped in every possible way for food.

The destruction of the small birds has gone on increasing, and in a corresponding ratio has proceeded the increase of those insects and reptiles which prey on the crops of grain and all kinds of vegetable food; and on these insect-tribes the small birds live. To that degree of alarm has the public mind been brought, that inquiry and investigation have been instituted, and have demonstrated the fact that the destruction of the beau-

tiful feathered songsters may, if continued, lead to something like positive famine.

In England we do not condescend to eat these beautiful little creatures. We eat no birds of less size than the Pigeon, or the Partridge, or the Snipe, or the Woodcock. But in France, nothing in the shape of a bird, however small, comes amiss to the French.

The translation of the document in question having been printed in the *Times*, it has been reprinted in other newspapers, as also in the *Zoologist*, a periodical which we take in, leading to much discussion in the journals with the view to correct the popular errors which too much prevail in this country as to the influences these useful and beautiful creatures, the birds, exert on other animal and vegetable organisations.

It is an acknowledged truth that in the Divine government the arrangements of the Almighty, in His perfect wisdom, are adapted to maintain an equilibrium among living beings, so that there shall be a due proportion of each in their proper places, not requiring the aid of us poor, fallible creatures, in the fullness of our self-conceit, to adjust the balance.

Although the Sparrows levy a small contribution on the farmer's grain, yet the far greater portion of their food is from injurious insects, and the whole of the food they give their young is from the tribe of insects. At the beginning of the world man would have succumbed in the unequal struggle if God had not given him in the bird a powerful auxiliary, a faithful ally, which wonderfully accomplishes the task which man is incapable of performing—in fact, against his enemies of the insect world man would be powerless without the bird.

If the Sparrows and the Rooks make us pay very moderately for their services, all other birds, the Pigeon excepted, are devourers of insects, and render us gratuitous services. Among them are nocturnal birds, as the Barn Owl, Bats, and others, which ignorance foolishly persecutes. The Woodpecker, the various species of the Swallow, the charming songster of the fields, the Nightingale, Black Caps, Redbreasts, Redstarts, Wagtails, Larks, Wrens, and other small birds, render most invaluable services. As an example of the proceedings of these useful creatures, two Swallows were killed, and in their stomachs were found the remains of 5182 insects, giving to each bird 518 insects destroyed; analogous results attend the Hedge Sparrows. With respect to our formidable enemies, the cockchafer and a host of others, the cockchafer deposits from 70 to 100 eggs at a time, which are soon transformed into white grubs, which for two or three years live on the roots of our most valuable vegetables. The weevil produces from 70 to 90 eggs, which, laid in so many grains of corn become larvae that eat them all up.

"Thus the bird can live without man, but man cannot live without the bird." Common sense and right-minded men would come to the conclusion that man, grateful for the invaluable services of these friends and faithful allies, as small birds, would take them under his special protection; yet man, by a strange blindness and ignorance, is often the greatest enemy of these gentle and beautiful creatures, and as if it was not enough that we should from sheer ignorance carry on this war of extermination, parents allow their toys in their bird-nesting sports to rob the nests of their eggs, and frequently of the young birds—a senseless and useless sport, as usually pursued, and, without spurious or sentimental feeling, we may fairly suppose some pain to the little parents in the bereavement.

We see in domesticated birds the anxious assiduity with which the hen particularly care for and foster their young—how much and with what sedulous care the common hen bird shelters her chickens under her wings. With a similar instinctive affection we may fairly suppose the birds in the hedges feed and cherish their young, and we ought to feel the cruelty inflicted on the poor little creatures by the thoughtless and wilful boy who robs the nest generally from mere wantonness, or to very little purpose. Bird-nesting ought not, therefore, to be tolerated; and the clergy, with the schoolmaster, should be enabled to impart useful and humane knowledge on these subjects of natural history to their pupils.

That these defenceless little creatures have been enabled to survive this grievous warfare is one of the mysteries only to be explained by the wonderful goodness of God, who incessantly redeems and corrects the errors and faults of that fallible creature, man.

In *All the Year Round*, a popular periodical, is a facetious version of the French report, in the form of a congress of birds

—Sir Robert Redbreast, K.G.—*i.e.*, Knight of the Garden, in the chair, by acclamation of wings.

The version of the French document is pleasantly written, and is agreeable in general for the general reader, as stating the ravages as respects all vegetable productions by myriads of insects, all ended with prodigious fecundity, and living exclusively on valuable vegetable productions; among them, wheat and other corn plants are destroyed at the root by the grub of the cockchafer and by other vermin; in the grain by the weevil. The cruciferous plants, as the turnips, by other insects; others take up their abode in the pod of beans, peas, and lentils.

At bottom the vital sap is intercepted by underground and burrowing insects. After these mice and rats exact their share, so that nearly half a crop may be lost but for our friends, the small birds.

Those who have travelled through France, even merely to Paris, must have observed almost all the land are open fields, with few living hedges, and, therefore, affording but little shelter for small birds.

Those who travel at home observe the continual grubbing of hedgerows, and living small fields together to make large ones, to have more land under the plough, which, considering that we are large importers of grain, can hardly be disapproved, although we must lament the diminution of shelter and protection for our little and invaluable friends, the birds.

In all probability the French government will have stringent measures to restrain the wholesale destruction of small birds. In this country we shall rely on gentle moral reason and suasion to effect the same objects; and in the hope of the entire discontinuance of the "Sparrow clubs," the patrons and promoters of which will be assured that they are making a sad mistake in the destruction of little creatures, which, living partly on grain, repay the gardener and the farmer tenfold by feeding much more on those minute animals, many of them too small to be visible to the human eye without the aid of the microscope, but visible to those quick-sighted birds, as well as the grubs, caterpillars, and all other animals which prey on and destroy the products of horticulture and agriculture.

VARIETIES.

SAWDUST AS A FIXER OF AMMONIA.—Sawdust is one of the very best absorbents for liquid manure. Mixed with diluted sulphuric acid, it is one of the best materials for the fixing of the ammonia which is given off in stables. The following experiments have been put on record.—A shallow basin, in which sawdust, moistened with diluted sulphuric acid, was spread, was hung up in a stable, and, in the course of three weeks, all the acid in the sawdust was completely neutralised by the ammonia in the air of the stable, and a considerable quantity of sulphate of ammonia was formed in this manner. For this reason sawdust mixed with sulphuric acid is recommended as a means of keeping stables sweet and wholesome. The acid should be diluted with forty-five times its bulk of water before it is applied to the sawdust. Just enough should be applied to make the sawdust feel damp. On account of its porosity, sawdust retains the acid very perfectly, and presents a large surface for the absorption of the ammonia.—(*London Review*.)

OUR LETTER BOX.

TRIMMING SPANISH FOWLS (*Lanius*).—Picking out the feathers over the eyes of a Spanish fowl would not only close the eye, if detected, but subject you to the danger of having the feathers on a card and snipe up against the eye. The object of poddy exhibitions is to promote the breeding of fowls having particular required points *naturally*, not by trimming.

WARNING A ROOST HOUSE FOR BANTAMS (*C. Thompson*).—We are not friendly to any method of building in the way of stoves or hot-water pipes for poultry. We are quite sure to state that degree of cold will kill them, as, although such fowls as we had two years since will spoil cents and freeze to us, yet we never lost one fowl by it. It on a bare spot without shelter, had frost and east winds will kill poultry; but when they can find shelter, and, above all, where they are well fed, cold will not hurt them. Injury is far more likely to result when they have a heated place for a cold atmosphere. Any extra warmth should be given by extra feeding.

GREEN FAVES (*A. Sabin*).—One pair of fowls from our "Pen try Book for the Year," answer to both your queries. "The pair; therefore an equal number of each sex must be kept." It is the hen only which utters the peculiar cry of "Come back." The note of the cock bird is a kind of wail. You can have the cock free by putting from our office by sending seven penny postage stamps with your direction.

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last thirty-five years, the average highest and lowest temperatures of these days are 41.0° and 31.7° respectively. The greatest heat, 58°, occurred on the 23rd in 1834; and the lowest cold, 7°, on the 26th in 1858. During the period 129 days were fine, and on 169 rain fell.

THE PROCESS OF FERTILISATION.

SINNINGIA, and not Linningia (as printed at page 310), was the broken-down family which was the cause and precursor of the present race of Gloxinias. At that time there were only two kinds of Gloxinias in cultivation—the then recently-introduced *Gloxinia speciosa*, and the oldest of them all,

the *Gloxinia maculata*. Both would seed very freely, each by its own pollen, but neither would unite by the pollen of the other. Both were favourites with gardeners who felt a family-like loss at their want of reciprocity; when one of them, the said gardeners, stepped out of the ranks and turned a rank radical, turned also the genus *Sinningia* through *Sinningia maculata* to a botanical figment, united it by its pollen with the newer *Gloxinia speciosa* which produced glauca or glauceseens, the parent of the present race of garden Gloxinias. It may be stated as an historical fact, that the raiser of glauceseens thought so little of it that he turned out some scores of "roots" of it with the garden rubbish, the rubbish was trampled by cattle, and most of the *Gloxinia* bulbs were thus destroyed. One plant was kept to prove the cross. Mr. Low, sen., of the firm from Clapton, saw that plant, and picked out some "roots" from the cattle track, sold the first three of them to Messrs. Glenny and Harris, and to Mrs. Lawrence, for 21s. each. Just think of that when you have a cross seedling which may not be worth picking up on the street; if it is not a barren one never mind its present looks, give up a florist's notion at once, and call it the progenitor of some prodigious good thing, and the very daring will help to bring your prospects to good account.

Before the first crossed *Fuchsia* was in the market, in 1836, it was clearly proved, and agreed upon by all practicals who had seen the plants, that the Mexican species *gracilis*, *virgata*, *conica*, *elegans*, *globosa*, and *macrostemon*, were all convertible, the one for the other, as the merest varieties of garden seedlings—say *Asters* or *Poppies*. And not only so, but that excopticata of New Zealand, and discolor of Port Famine, with the wood of which Mr. Darwin had to cook his own meals when on that station, could be produced by the mixtures of Mexican kinds. Even the most dissimilar kind in the family, the *Fuchsia arborescens*, crossed with some one of the Mexican fry, and produced a weeping *Fuchsia*, which trailed on the ground like a *Strawberry*, as I can vouch for, as it appeared among my own seedlings. Two very good chances of two new races had been left slip in *Fuchsia*.

An entire new race of *Fuchsias* might yet be had, to No. 43.—VOL. II., NEW SERIES.

bloom exactly as does the common *Laurustinus*. The second would be less easily obtained, and the primitive moves for finding it are now too far from my mark. *Fuchsia fulgens* and *corymbiflora* never well agreed in crossing the species of former days, the foliage was too coarse, and could not be subdued—at least so it was said; but perseverance never tried to prove the question, and if we lost sight by that means, just put it down in the book against the florists' account. One thing the long *Fuchsias* had done, but ten to one if ever you heard of it to this day—it made dissenters of one-half of the gardeners who knew it, and of every one of the practical crossers. I say practical crossers, for at that time we had many fancy men in the line of crossing; that was a fancy which could do any fancy thing without doing it at all. What they dissented about was the way some botanists said the pollen grains found their way into the heart of the seed-pods, and to all or so many of the yet unfertilised seeds in embryo.

It has been said by learned men, and men more learned believe the thing to this hour, that the pollen has the power to separate itself into minute grains when it is sticking fast as in a pitch-plaster, on the summit of a viscous, or clammy, or sticky stigma, and that these minute grains of pollen go through very small tubes in the style as bullets go into Minnie rifles, or sink down by their own weight through the said tubes, as one might say. From the bottom of the style in flowers, there is a bridge across to the seeds, which they call the placenta, or plain bridge as one might say. How the pollen grains got over the bridge, or got along it, no one could ever tell; but some one certainly said he saw with a glass the pollen grain going down to the end of the bridge, and if he had paid the toll he might just as likely have seen the grain of pollen pass along the bridge and stop at the door of the seed itself till it was admitted. All the men who were practically engaged on crossing found a great difficulty in believing this story. They put the question thus—Do you suppose that by a beat to the tails of a miller's cat which blew the dust on to the side of a tar barrel fresh from the filling, the nearest thing we can think of to liken to the dust of the pollen on to the point of the style, would give the property to the dust to separate itself into distinct grains like small shot in a pouch or belt?

Another version of this wonder was, that each grain of pollen, as it stuck in the clammy juice on the stigma, had the power of forming a tube which reached from the stigma to the ovary, and so impregnated the seeds. In that case the late Mr. Shepherd, of the Liverpool Botanic Garden, had a bulb called *Hymenocallis pedalis*, in which the style was a foot long, and it had been mentioned as a case of extreme probability that a body so small as a grain of pollen could, from its own bulk, produce a tube of so much length; but that bulb was little known at the time to gardeners, though it had been figured indifferently in the nineteenth volume of the "Botanical Register," plate 1641. It was not till the long-tubed *Fuchsias* were in cultivation that gardeners,

who were acquainted with crossing, could see the full force of the difficulty which attended those explanations of the means by which the virtue of the pollen reached the ovules. Then, although they could not gainsay it, they would not assent to it; and the sum of their objections was thus expressed—that in all the wonderful contrivances of Almighty wisdom to effect apparently difficult purposes, they had perceived that no unnecessary complication of machinery was used.

The question how the influence of the pollen reaches the ovary is yet in that same position, save and except that most gardeners believe in the mode I once explained in these pages—a nice guess however—that the pollen grains burst on coming in contact with the gummy fluid on the stigma, and that the contents of the pollen grains, like melted sugar in water, get into the circulation like the rest of the juices of a plant; and seeing that every product of a plant depended on some part or other of the circulation of that plant—the last produced, the vitality of the seed must also depend on a part of the circulation. But whether any of these theories of the way seeds are fertilised be the correct one, no one as far as I know can tell. The probability is, that each party is well satisfied with their own way of explaining the subject, and glad enough to hold aloof from a very difficult problem.

Rare bulbs being so scarce and so little known to the public, it would be of small practical value to enumerate all that is known about their capacity for crossing. Not at present at all events. But there is one more subject connected with crossing which has not yet had the advantage of a public discussion. There are more stages than one in the process of fertilisation, though, hitherto, the work has been spoken of and written about as if the whole process consisted of one event. But the seed-pod is, as it were, the first part to take its own share of the process of crossing. You may fertilise a seed-pod so to speak, and not have a single seed in it, nor the appearance of one; and yet without the crossing, or, at least, the application of pollen, that pod would never have gone on to maturity, but fall off with the falling of the flower. In the second stage of fertilisation you only quicken the lobes or substance of the seed. If it were a Pea it was made for the pot only—there was no quickening of the germ within it. The different sections of Hibiscus, and of Cactus, and some others, are well-known instances to hybridisers of this far-and-no-farther quickening when members of the sections are approached by pollen.

These two stages in the fertilising process are quite common. I told you not long since how I saved 10s. clear from a knowledge of that fact. I would not pay down for two seeds of Mangles' Variegated Geranium till I had ascertained if the process of fertilising them was complete or not, and, as it happened, the two first stages of the process had been reached, but that is very rare indeed in the Geranium order, as far as I have had dealings with the members. I have only one more such instance among Geraniums which I can call to mind, and how it happened throws a glimmer on the art of the cross-breeder. I well recollect having had a fine seedling open its first flowers late in October, and although it is foolish work to cross the first flowers of a very young seedling in June, or, say in the best of weather, I could not keep down the ruling passion. I ripened several pods from that cross, but none of the seeds had the germ of life quickened or fertilised, and, of course, they did not sprout.

The old *Abströmia peregriua* will ripen its seed-pod, and some few apparently ripened seeds if you touch it with the pollen of any of its near-st allies; but you, or at least I, could never get a crossed seed from that *Abströmia* to sprout. *Hookeriana* is the next nearest to doing the same; but I believe the whole genus will give more or less evidence of the fact that full fertilisation consists of more than one process of nature. Then what you read in books about the pod beginning to swell at such and such a time after the pollen takes effect is only one of those fictions which are founded on facts; the case is as is said generally, but not always.

The lesson to learn from the fact that pods and seeds do swell and ripen sometimes without the germ having been fertilised is this—that you should apply the pollen in such doubtful cases four or five times the same day; for there never was such a thing as a stigma getting fit a second time, or after a day's interval. But as we know to a certainty that there are degrees if not four degrees in the quickening process, we may be excused for supposing that more pollen and most pollen will reach the degrees farther and farthest if we apply it in time—that is, ere the first and final moisture on the stigma is dried

up; and those which never show the moisture are more safe, one would think, if all the pollen it needs has been collected on the same day, or at the farthest on the morrow.

But, to go still closer to the practice. When you see a chance like this, what do you suppose would have been the result if Mr. Smith, of York, had applied the pollen of the Golden Chain on Mangles' Variegated at eight o'clock in the morning, again about eleven in the forenoon of that day, again after he had his dinner—say two o'clock, and last of all just before he went in to tea? Just think this over in your own mind. Perhaps it was the very bait for the hook to catch some one to our ways of crossing without being cross ourselves. Everybody likes flowers, but none half so much as those who pry into the secrets of nature about their origin and the ways to improve them.

This, the successive stages by which the impregnation of seeds and seed-pods is effected in some plants, has been prominently brought to my recollection by a pamphlet for which I am indebted to the kindness of Mr. Darwin. It is from the "Journal of the Proceedings of the Linnaean Society for 1862," and treats "on the two forms, or dimorphic condition in the species of *Primula*, and on their remarkable sexual relations." A course of interesting experiments by Mr. Darwin on the "pin-eyed" and "thrum-eyed" kinds of *Primulas*, and how the reversed position of the style and stamens in these flowers affects the number or the quantity of seeds which they produce.

Referring to Cowslips and Primroses, Mr. Darwin found that "the two forms exist in the wild state in about equal numbers;" also "that the existence of the two forms is very general, if not universal, in the genus *Primula*." In every case which he tried he found that the "pin-eyed," or long-styled plants, produced a less number, or quantity, of seeds than the "thrum-eyed," or short-style ones. Mr. Darwin thinks "the cause of this difference is, that when the corolla of the long-styled plants falls off, the shorter stamens near the bottom of the tube are necessarily dragged over the stigma, and leave pollen on it; . . . whereas, in the short-styled flowers, the stamens are seated at the mouth of the corolla, and in falling off do not brush over the lowly-seated stigma."

This is just the opinion I have been advocating, the less pollen the fewer seeds, or the still fewer number of the stages of fertilisation. Here, then, is where practice and science are brought face to face on equal grounds. The deductions which Mr. Darwin draws from this subject are, like others of his reasoning powers, most profound, and very interesting; but I must here refer the reader to the "Proceedings of the Linnaean Society" aforesaid, and ask the question, Would not the repeated application of the pollen, as above, have the effect of making up the deficiencies in all the cases mentioned both by Mr. Darwin and by Gärtner?

D. BEATON.

ICE-HOUSES, AND THE CONDITIONS NECESSARY FOR KEEPING ICE.

THERE is, perhaps, nothing in the horticultural department on which such a diversity of opinion exists as on the preservation of ice. So diametrically opposite are the views taken on this subject, that the inexperienced public may, naturally enough, feel puzzled which way to reconcile the conflicting opinions given. The difficulties in the matter are these:—An experiment can only be made once a year, and it sometimes happens, perhaps, to be made under such fortunate or unfortunate circumstances, as to have more influence on the result than the practical operator gives it credit for; and the blame or credit, whichever it may happen to be, is all absorbed in the one feature or mode of treatment in which the usual course of ice-keeping is departed from. Thus, for instance, Mr. A salts his ice in 1852, and finds it keeps better than it did the year before, forgetting, at the same time, that his ice-house was supplying his family several months earlier in 1851 than was required in 1852. Another puts straw around one year with a like result, and numberless experiments are being made year after year, with results more or less conflicting, so that a few notes on the treatment ice received in years gone by, as well as the views held about it at the present day, will, perhaps, be the best way to explain the matter.

I believe if we trace the history of ice-keeping by artificial means to its original source, we shall find that large heaps of it piled up in some shady situation to have been the first method

taken. Certainly the plan was not uncommon about the time that "London's Gardeners' Magazine" first made its appearance in 1824, and it is only taking a lesson out of Nature's book by adopting that plan. Drifted snow passes over the ledge of some rocky precipice into some ravine or hollow; remains there a greater or less length of time, according to its quantity and the situation it is placed in, the climate, and other conditions. Some of these are so favourable, that snow is often preserved a long time in a natural way. Only about six years ago, a quantity of snow was taken out of a chalk-pit a few miles from here (Kent) towards the end of June, that had been drifted into that position. I have known a north wind drive the snow into the recesses on the southern side of a ridge, and have seen it lie glittering in the sun for weeks—up to the 1st May, even in Kent; but it is needless to say it was the large quantity that took the longer time to waste away. And so it is with heaps artificially made. If we took the trouble to make a heap of pure ice of anything like the dimensions of an arctic iceberg, there is no doubt but it would keep—*i.e.*, a part of it would keep the whole year, or several years, perhaps; but reduce that iceberg to the size of a haycock, and see how soon it will be gone. If it were possible to transport an iceberg from Baffin's Bay to the Bay of Bengal, there is no doubt but its immense bulk would require a considerable time to melt even when under a tropical sun; but it would dissolve away quicker there than it would in the waters of the North Atlantic. This is certainly an unquestionable fact, and it teaches us that the lower the temperature is the longer the ice will keep; and assuredly from this it may be inferred that the colder the atmosphere in which it is kept in an artificial condition, the better and longer it is likely to keep. This is certainly at variance with the ideas of those who advise out-door ice-stacks, or well-ventilated ice-houses to keep it in; but as these observations are made merely to point out the condition ice and snow are preserved for lengthened periods in a natural condition, the artificial way may be treated of next.

Having said that out-door stacks of ice were not uncommon upwards of thirty years ago, and the manner of storing ice away in a well, called, perhaps correctly enough, an ice-house, of the same construction then as many are now, it becomes us to inquire what improvement has been effected since that time. To this a qualified answer must be given. New ideas have been put forth, tried and exploded. Some time about 1830 salt was recommended to be put in with the ice, and some advised water—and one writer, wishful, perhaps, of attaining a high name for a novel experiment, insisted on hot water being used. But whatever may have been the merits of water I cannot say. One thing I felt certain—that salt did no good; and I inquired through the gardening periodicals of the time, and was answered to my satisfaction by the late Professor Henslow, who disapproved of salt being used as a preservative to ice, though to increase intensity of cold for a time it was recommendable. This latter idea has been acted upon by confectioners and others from time immemorial. Salting ice at the time of storing it away has been, therefore, abandoned in a general way.

Next came the question of drainage; and if that be not effected sufficiently by the natural condition of the ground, all parties agree that ice will not keep in a pool of water, and an efficient drain must be provided.

More latterly the subject of ventilating ice-houses has been treated upon, especially by our worthy coadjutor Mr. Beaton; but, although I have had a fair share of experience in ice-house-filling and management, I confess I should have great reluctance in advising both the top and bottom ventilation Mr. Beaton speaks of. If his view of the case be right, then the contrivers of those ingenious apparatuses called refrigerators must be all wrong, for all these are made with the express object of excluding air, the best class of them doing so by the most approved mechanical method for attaining that object, and we all know they do keep ice well. In what way, then, can air be admitted in large quantities into an ice-house, to improve the keeping qualities of the ice, when we are assured by unquestionable evidence that ice keeps better in a box when shut out from all communication with the outward atmosphere than when exposed to it? This being so I can hardly see in which way the old-fashioned method of shutting out the external atmosphere from our ice-houses was at fault. True, in some cases ice kept badly in some houses; perhaps from other causes than want of fresh air, and after considerable alteration, including some mode of ventilation resulting in the ice keeping better, it is hardly fair to give the air-hole all

the credit of it. But as examples are always preferable to opinion I will record some cases that have come under my own notice.

The first ice-house that I ever had anything to do with was one of a class of which there are, I believe, hundreds in the kingdom—a broad well some 12 feet or more deep, lined with brickwork, and domed over at top, with a doorway near the top on the north side, and a passage 6 feet or 8 feet long leading to it with another outward door, the whole being on the side of a steep hill facing the north and overhung by trees; in fact, it was in a wood. I forget whether there was any drain from it or not, but the rocky nature of the ground would receive any amount of water that would be created by the melted ice. At the time I speak, upwards of thirty years ago, it was customary after the ice-house was filled up late in the winter, to plaster with mortar all the crevices in the inner door, and pile straw against it also, all with the avowed object of keeping out air, and the ice kept well in this house, as well as in that of any I have had anything to do with. I need hardly say that the plastering-up of the door was not attended to every time the house was opened; but when there was a likelihood of its not being likely to be so for some days it was done—the mortar, never hardening, it was much easier done than might be expected. I may also add that straw also was laid upon the ice, and at the time of storing it away straw was placed against the sides. Now, all this was done for the purpose of keeping out air, and it certainly preserved the ice. The plan presents nothing novel in it—in fact, with a very slight variation it is the same as is adopted at the present day, and in the greatest number of places.

I now come to another case that came under my notice, of which, however, I had not so good a chance to see all the operation, but witnessed the result afterwards—an ice-house sunk in the middle of a field, the ground affording but little undulation, and it was not advisable to have much of a mound or anything to denote at a little distance that there was an ice-house there: consequently, the well or whole house was under the surface with a fair covering of earth over the top. In this house the ice kept very badly. Its exposed position was by some attributed as the cause, while others thought it was the effect of deficient drainage, and a drain was put in at a great expense, and still the house did not give satisfaction, and, I believe, has been abandoned. There were many opinions and conjectures about this ice-house, and several remedies in a small way tried. I think leaving the doors partly open was one, but I am not sure of this. Certain it is that none of the means tried effected the desired object, and it has puzzled me since to assign a cause for its not keeping ice. I have seen one quite as fully exposed to do, and in ground apparently differing very little from the one in question. Whether there was any spring that communicated warmth to the brickwork, and thereby melted the ice or not I cannot say. Certainly there was no standing water in the bottom of the ice-well, as I have seen in another place that failed, and it was cured by the water being drained off; but in this case the evil lay in something else, and as I have heard of more than one ice-house failing to preserve its contents as it ought to do, it is evident our knowledge of the laws which determine its keeping or otherwise is very imperfect; and I am unwilling to believe that a large influx and efflux of air is what is wanted. On the contrary, I cannot bring myself to the belief that the old plan of excluding it as much as can conveniently be done was wrong, and an example may easily be obtained. Let the best air-tight refrigerator be filled with ice and the lid put down; at the same time let the like quantity of ice of the same description be put into a deal box with numerous holes bored in its sides, top, and bottom to admit the air; place this box and the refrigerator side by side, and if the perforated box keeps the article longest then I acknowledge myself to be wrong.

I cannot see the utility of allowing currents of summer air heated to 70° or more to pass through an ice-house as being likely to effect any other object than cooling that air, and, of course, warming the ice. If ice had been a fermenting or putrefactive body calculated to generate heat or noxious gases, I should say by all means ventilate; but as it is itself cooler than the air which surrounds it, it does not even give off a vapour. Damp there certainly is, and ever will be as long as there is a particle of ice there; and I am not sure but that warming the air of the house by influxes from the outside will increase the damp in the same way as a warm body resting on the cold earth sneaks up the moisture by capillary attraction. I cannot see, therefore, in which way mere ventilation can do otherwise than harm.

It is perfectly true that the best-contrived house I have ever seen was far from being air-tight, as that subtle fluid is sure to find its way through most ordinary contrivances in the door-fitting and stuffing way; and the little that gets in that way is sufficient to keep the place sweet and fit to inhale when the door is first opened, there being, as I have stated above, no noxious exhalations from ice alone. If we could command such a current of air as blows in winter across the bleak coasts of Labrador or northern Siberia, I have no doubt but it would improve the keeping qualities of our ice; but when Science furnishes us with such an element, ice-houses may be dispensed with. In the meantime let experiments be made, and let those who have already made them come forward and publish the result. I am far from arrogating to myself as a being infallible, but, on the contrary, I admit being puzzled to account for the bad keeping qualification of more than one ice-house I have come in contact with. The only reasons I could give were far from satisfactory to myself, but there nevertheless may be some truth in the matter. Its illustrations, however, require a somewhat lengthened explanation, which I submit to the opinion of those more capable of giving a just one than I profess to be. It is this:—

We all know that the agent fatal to ice-keeping is heat; and as water and similar liquids become solid when the atmosphere falls below 32°, in like manner they pass again into the liquid form when the temperature is raised above 32°, and, if the heat be continued, the liquid would be converted into a gaseous vapour and pass off as steam. This, however, we need not follow further; only every reader is perhaps not aware that the steam-baking vapour from spring water fresh from the earth during a severe frost is a precisely similar case to the steam from a hot cup of tea in an ordinary room—in both cases the liquid giving off the vapour being warmer than the atmosphere by which it is surrounded, but the latter, being the largest body, eventually cools it down to its own temperature; and the well-known steam, after running a certain distance, ceases to give off the steam spoken of, the water being cooled down to a condition much nearer that of the atmosphere. Now when the atmosphere and the water are alike in temperature there is no exhalation; and when the air becomes the warmer the water receives heat from it, and the water in summer is much warmer than that of the springs. This may, perhaps, be thought to have no relation to ice-keeping, but it is given to show the effects produced by heat, which is the element we have to deal with; and the natural laws given above are those which exercise their baneful influence in the ice-house. The small body supplying heat to the larger, as in the cases above, its effects are lost, or so unappreciable as not to deserve notice; but where heat is imparted by a large body to a small one, its effects, of course, are more perceptible; and this is the case with ice in an ice-house, as will be shown.

It is well-known generally, that heat is communicated from one object to another by radiation or conduction. An open fire forms a good example of the first of these, and the warmth imparted to one end of a bar of metal when the other end is put into the fire is an example of the second kind. But as all substances are not alike conductors of heat, a, for instance, glass is a poor one compared with most metals, we may, perhaps, find out by a similar line of reasoning why one ice-house keeps ice badly, and another one well by some analogous case; for as we all know the temperature of the earth a few feet below the surface is 15°, or more, higher than that of freezing water, it is reasonable to suppose that the communication between the warmed walls of the ice-house and the ice itself is the cause of the latter melting; but if these walls could be deprived of their warmth, and reduced to a temperature of 34°, or thereabouts, the loss of ice would be much smaller.

Now, how is this to be accomplished? is the next question. But why it does not specifically fall to 32°, is exactly owing to its continuing to receive heat from behind by conduction; and as all substances are not all the good conductors of heat—glass, for instance, being less so than metals, so it is likely there is the same difference in the stratum of the earth surrounding the brick casing of the ice-house, one material being to a great extent inert in that way, and this producing a good keeping ice-house, while another is a good conductor, and, consequently, by continually supplying heat, melts and dissolves the ice. This I verily believe to be the key to the whole secret; and if I might venture an opinion of the description of material most likely to cause this maintenance of heat, I would say that it is the large amount of water some strata hold, or are supplied with, which

being all drawn towards the ice-house by its being an open drain or sink, convey thither a never-ending stream of warmth, which acting on the ice effects its destruction much sooner than if there were no warm-water pipes (for such, in fact, these rivers of spring water really are) pointing towards it. It is not the mere fact of damp that causes this water, but the water being warmer than the ice warms the lining of the ice-house, and thus keeps up a higher temperature than is compatible with its preservation. And I cannot see in which way admitting summer air would be likely to lower this temperature: on the contrary, I think it must make matters worse. Other strata may also act as conductors as well as water, but the continuous motion of the latter, and that in all likelihood pointing in the direction of the ice-wall, seem to be the most likely source of communicating heat, even where no visible signs of the spring water manifest themselves in the ice-house; for we suppose the outlet-drain to be in active working order, and the water channels diverging in all directions from the centre of attraction, trickle through the strata behind the brickwork and entering the drain are conveyed away. Perhaps the worst-keeping ice-houses are of this class.

Now, the next question is, What remedy is there for an evil of this kind? The most practical one seems to be to shut off the communication between the brick lining of the ice-house and the ice by another wall having a cavity between, and only united to it by a few ties possessing the least possible conductive power—say a 12-inch lining of brickwork secured at places about a foot apart, with slips of slate, and allowing a cavity of about 3 inches. This cavity need not be ventilated for any purpose that I can see. There is nothing inside of it to decay; it is not like dry rot attacking a timber floor; and all its duties are to resist the transmission of heat from the earth to the ice-house, and the more stagnant it is the more it is likely to do this. I have, therefore, no hesitation in advising this inner wall or lining to such ice-houses as keep ice badly; and making sure that the drainage is perfect, I cannot bring myself to the belief that ventilation is an item wanted in preserving such an article as ice, which is destroyed by only one element—heat. By adopting all means likely to arrest that agent we are more likely to be successful. Most substances keep the longest time when excluded from the air. Timber embedded in a morass is a more durable article than the same material in a building by very many centuries, and we have all heard of the exhumation of bodies in perfectly fresh condition that have been interred for hundreds of years. Many other examples might be given, but I hope to see the matter taken up by others who have had practical experience on the keeping of ice, as I by no means assert that the hypothesis here put forth is entirely right, as I have seen enough of ice-keeping to learn diffidence in my own conclusions, that I hereby invite others to give us their views on the matter. I may also add, what is more practical, at the same time not more satisfactory, that I have never been successful in forming an ice-heap out of doors: those who have will, perhaps, be kind enough to report the conditions of their case. Mr. Weston has on more occasions than one explained how he accomplished it, and the more credit is due to him for so keeping ice; but I know of more than one as well as myself who have been unfortunate this way, so that I should like to know the failure as well as the successful results of the somewhat conflicting opinions.—J. ROSSON.

HEATING BY A HOT-WATER TANK—TAN ON A FLUE—GERANIUM FLOWERS DECAYING.

I HAVE a greenhouse, 12 feet long, 10 feet wide, 6 feet at front, and 10 feet at back. Would a tank, 1½ feet long, and 1 foot wide be sufficient to heat it with?

I am about to make a pit for striking cuttings, the pit will be 6 feet long, and 5 feet wide; the tank will be the same size. How deep should it be to hold the heat for several hours? Would it be safe to put tan on the flue—do you think it would take fire?

I have some Geraniums coming to bloom, and when the flower-stalks get about 3 inches long the bloom drops off. Is it for the use of manure water? if so, what manure water should I want?—J. W. B.

[A tank of the width and length you specify will be sufficient if 6 inches deep; it is of no use having it much deeper, for it will not hold the heat much longer, the warmest liquid being always at the surface. The furnace and not the tank must be depended on for the storehouse of heat.

A tank of that width will not be sufficient for the pit for propagating; but you may double it and then it would do, and have one for bottom and one for top heat. We know nothing of where your flue is to be, but it will not do to put ten on it; it will get so dried if not turned that there would be risks; if you had a foot of stones, &c., between the two it would be different.

A little soot or superphosphate water—say an ounce to the gallon, might help your Geraniums in fine sunny weather. At present we suspect they are suffering from too high a temperature and want of air in this dull weather.]

MOVING AN OLD QUICK HEDGE.

Will old Quick move so as to form a good hedge quicker than new plants? I cut down an old hedge near the ground last spring, and it has, of course, thrown out abundance of new shoots. I am now going to grub this, and I want to form a new hedge. Do you advise me to use this? Can you give me any directions as to the best mode of proceeding?—B.

[Old White Thorns or Quick—say up to twenty or five and twenty years old, will remove and make a better hedge in one-half the time it would take young Quick to grow to be a complete hedge—that is to say, on the supposition that the old Thorns had not been grubbed-up as you mean to do yours, and that the land was well prepared for them. The way to take up old Thorns to make a new hedge with is exactly the same as for taking up Peach trees to renew a border or for potting them. Every fibre of the roots must be saved as carefully as if every one of the plants was worth at the least 20s. Then, according to the size and length of the roots, the trench for planting them in should be made to give them full free room. The trench ought not to be less than 3 feet wide, unless the soil is or has been recently under high cultivation. The bottom of the trench should be loosened—dug, in fact, to the depth of 18 inches; and if the soil is not good it should be spaded out, and the trench filled with the best of the top soil; and if you could give it some very rotten dung, as for Celery in a trench, all the better, and no weed should come within 2 feet of the new hedge for the first three years. Your old plants which you cut last spring, and which are now in "abundance of shoots," are in the best possible condition to remove; but you have not one week to spare in doing the work, and if you do not get it all finished by the middle of February you will lose one year and do hurt to the plants—it is now almost three months behind time.]

HEATING WITH EARTHENWARE PIPES FOR A FLUE.

I wish to heat a range of glass about 50 feet long, but one-third to be much hotter than the remainder for stove plants or Pines; one fire only to be used. Would clay pipes 10 inches in diameter, or an ordinary flue be the simplest and most effective? If the pipes went along three sides of the hotter part would it be sufficient, and along two sides of the cooler? then the fire being at A, the pipes or flue would follow the dotted line, ending in a chimney at B. Thus going round three sides of C, and two sides of D, how would you recommend that the pipes should be cleaned when foul with soot? I propose to have a brick chamber of 24 inches by 12 inches at every 12 feet, and at the turnings with a metal door at the top, to open when required to sweep the pipes. The pipes to enter at each end of the chamber, but not continue through them. Would this chamber interfere with the draught?

I would also wish to avoid sashes, as the opening and shutting them often shakes the glass, and allows rain to get in and decay the woodwork. I would effect the ventilation by trap-doors at back and front, and as in orchard-houses. My gardener insists that the ventilation cannot be managed without sashes, as air is required from the top.

I have heard that it is difficult to stanch the clay pipes so as to prevent the smoke escaping, but with flanges and fitting one into another, I think this difficulty could be easily overcome. Can you tell me where I should get these pipes, the best and cheapest, and what would be their price per foot?—B. STEVENSON.

[We have had considerable difficulty in making out the hand-

writing, and may not hit upon exactly what you want. So far as we understand, the plan proposed will not work. You propose to divide your house of 50 feet into two departments—a hothouse, c, and a cooler house, d; to have the fire at A, a flue

or pipe through D, and round three sides of C, to chimney B. The flue at D will be the hottest, and you must heat that before you can heat the hothouse, c. Now, that for either Pines or stove plants would often require heat when it would be very undesirable to have fire heat in the cool division. You ought to be able to heat one independently of the other, and the end where most heat is required should be next the fireplace. Now, keeping in view that you must use one fire, and that at A, it might thus be arranged—the flue could go round three sides

of c, to the chimney B, or if much bottom heat was wanted it might take a turn below the bed for that purpose. A close damper at E, would shut off all communication from D, unless when desirable. The matter would be still more simplified by having the fireplace as well as the chimney at B, and take two flues from the furnace, one for each place. If the one division was merely wanted to be a little hotter than the other, but both to be heated at the same time, then the flue or pipe might run at once from A to a chimney at E. If D was to be kept cool, however, there would not then be heat enough at C for Pine Apples, though by giving much less air at C than D, there could easily be some 10° of difference between them in temperature. If you had heated by hot water your proposed plan would answer well enough, as a flow and return might be enough in D, and you could add what pipes you liked in C.

Your proposed plan of fixing the pipes, by having small hollow pillars of bricks—say 12 feet to 20 feet apart, in which to insert the ends of the pipes—say 9 inches square inside, is what we have often recommended, as, if these are covered with a stout tile on the top, or, as you propose, an iron plate, these can be taken off and the pipes cleaned without disturbing them in their joints, &c. For this purpose soft-burned clay pipes, at least not too hard burned, answer better than those hard-burned, vitrified kinds used for sewage. They are made generally at most tile and pipe yards according to size at so much per yard. There is no difficulty in doing the joints. Good mortar made thick answers well, and so does Portland cement. No such pipes, however, should ever come within 2 yards or 3 yards of the fireplace, but should be joined to it by a brick flue, in a greenhouse—say 6 feet in length, and in a stove 12 feet to 15 feet in length. In fact, for stove heat, we would rather not use them at all, but have a nice flue; and that for a short distance from the flue at any rate, we would build with brick on bed.

From what we gather, we presume your house is to be a lean-to, as you give us neither height nor width; but if a span-roof more heating power will be wanted. For common things, the mode of air-giving in span-roofed orchard-houses will do—that is, giving air at the sides. For such plants as Pines, we should like means of giving air at the apex of the roof, for reasons frequently given. In a lean-to house there must be means of giving air at the top, or near the top, whether you have much heat on or not; but provided there are such means of air-giving it matters not where it is, though for several reasons it would be better to be given by openings near the top of the back wall than by any moving of the sashes. Front air can also be given in the front wall, whether that wall be wood or stone. There is such an advantage as respects economy in fixed roofs having no sashes, but good stout rafter sash-bars, that where openings on the back wall cannot be made, or a double wall-plate cannot be set on, with ventilators pivoted between them,

we would swing small ventilators at the top, or have a board to open all the way, which when shut would act as a repelling board to the glass.]

LUCULIA GRATISSIMA CULTURE.

HAVING seen a very fine plant of this at the gardens of the Right Hon. Lord Farnham, Cavan, Ireland, I thought a few words might be interesting to some of your readers, and as it is considered by most gardeners to be a plant of very difficult culture, which is my reason for giving these few remarks. The one in question is planted in a border in a cold greenhouse and trained to a wooden trellis at the back, occupying a space of 12 feet in height by 8 feet in breadth, literally clothed with fine trusses of flowers to the border. The day I saw it there were 330 trusses of blooms upon it, with 30 fully expanded, each truss measuring fully 7 inches in diameter. Is it a usual thing to bring this plant to so great perfection?—A SUBSCRIBER.

[The great secret of having most splendid *Luculias* is given here. There is no plant in cultivation, and there never was one in cultivation, more beautiful or more gratefully sent than this *Luculia*, and no plant has ever been more uniformly done through overkindness. Keep *Luculia* only two years a few degrees warmer than is natural for it and it wears out. Too much sunlight and 5° in winter over 40° will run it off its beauty in three years, and off the roots in five years. *Languera* roses and *Luculia gratissima* should receive the same degrees of light and warmth the year through. Neither of them should ever have more than 40° as the maximum heat the whole winter, and not the smallest attempt at forcing in the spring; and if the glass could be removed from over them in July and August both would do better than they have yet done. Ireland has now thoroughly beaten old England in this instance.]

PLANTING A BED OF ROSES.

I AM anxious to plant a bed with roses; the bed will hold three rows, and fifteen plants in each row. In your Number of July 16, 1861, page 297, I see a list of roses in shades, given by Mr. D. Beaton; but I can only have three rows instead of four. Now, which of the roses there named would you recommend, as I have not room for all, and in what order in the rows should they be planted? Would you have the darkest colour in the centre of each row and shade off to the sides, or how?—W. H. M.

[The roses from which Mr. Beaton had classed the colours in the way the colours tell best in beds or borders were most of them new kinds, and none of us yet can tell the order in which roses of different degrees of strength and growth ought to stand in beds or rows. All we can do under the circumstances is to show how the planting should be done, if we knew the size each kind of rose would attain, say, in three years—the utmost period that we allow our roses to stand without being taken up, root-pruned or not, and replanted for another two or three-year shift. The dark roses to be in the back row of a border-like yours, or in the centre of a bed of any shape. Then, if there is room for only three rows of plants, the nearest to rose-colour, or say the colour of the Cabbage Rose, should be in the centre row, and the blush and white roses in the front row. Again, in a case like yours the strongest grower of the dark roses should be planted in the centre of the row, and the next strongest right and left of the centre, and so on in gradation to either end. The rows would then seem to “swell” up from both ends to the centre. Again, instead of planting fifteen kinds of dark roses in the back row, we would plant in pairs of one kind on either side of the centre; the centre plant would then be the key plant to read the arrangement of that row from. The middle row would be on the same principle throughout, the most rose-like rose in the centre of the row, the next strongest nearest to rose (cabbage-rose colour) in pairs or singly on each side of the centre, and shading down to each end with lighter and more light shades of rose, and in the centre of the front row would be the strongest grower again, and the best blush rose, and on each side of it a lighter blush; then falling off to either end in shades till you come to pure white. The whole experience of the whole of the Rose-growers of Europe could not plant your border exactly as it should be from our arrangement and list of colours made last summer, the best that could be done would only be an approximate experiment; but a man on

the spot would in two years be able to arrange them to the very letter—to it, perhaps, with the very same plants, as that might be an impossibility, but surely with but few additional ones. The first rose in every shade of colour was our choice, the second our next choice, and so on; that is the only key we can give you as to sorts, as we have no more preference for our choice than we should have for that of any rose-fancier. All such matters of fancy should be free as air in everything which relates to plants.]

THE CAMELLIA AND ITS CULTURE.—No. 2.

EVERY practical cultivator has his own particular compost for potting any given species of plants; and all the instructions, either written or verbal, by the most successful cultivators in Great Britain and elsewhere will never be exactly imitated; and it is not necessary that it should be to the very letter. Our views, then, on the mechanical and even the chemical composition of the soil, in so far as a per-centum or two of the prime ingredient is concerned, either one way or the other, are not empirical. We should be inclined to lay considerably more stress on a due observance to its proper physical condition and capacity.

A very good compost consists of two parts of either black, brown, or hazel loam abounding in fibre, one part of sandy peat, and one part of gritty sand. If the compost were subjected to a careful analysis there would be found so many organic and so many inorganic substances—some dozen or fourteen in all, sizes, of size, forming by far the most formidable ingredient; others almost from their inappreciable quantity scarcely perceptible and yet necessary towards the well-being of the growing plant, all united together to form one harmonious whole. What an amount of gratification it must afford the practical gardener or farmer to be able to master such analytical tests and all their niceties! As for myself I am but a tyro in these matters, but am learning more and more to know the value of even the rudiments of such a science.

With reference to the loam spoken of, I have gathered it by the way-side, on the slopes of the running brook, and on the knolls of plantations—the higher and drier all the better. In fact, I do not know of a single locality where a very good texture of the above could not be found. From 2 inches to 3 inches is sufficiently thick to cut the turves for potting purposes. The richer in vegetable fibre—not decayed fibre, or lucus as chemists call it, but living organic matter—so much the better. If the turves possess that clammy richness which at once indicates a larger proportion of alumina, they must be toned down with opening ingredients in preparing the compost. It may be as well to mention that all composts are more suitable for the well-being of plants if they have been piled up under cover for at least six months previous to using them. This probatory period kills the roots, which if used at once would be a frile source of annoyance to the cultivator; while at the same time, and which is of far more consequence, the evaporation of the moisture therefrom mellifies the tenacious or cohesive tendency of the turves, and renders them better fitted to commingle with other ingredients. If this be sound practical doctrine it will at once be obvious to all that the compost, or rather the turves, before broken down to mix with foreign matter, should be well ventilated and protected from rain.

That elastic peat, of which there is abundance all over the country, forming, as it does, in low-lying, undrained, marshy places, is not that ingredient recommended above. Nevertheless, such is capable of being reduced to a proper consistency by charring, although by no means an equivalent for the peat which has been formed on the elevated rocks of the Cambrian and Gneiss systems, which are generally all but barren, agriculturally speaking, and yet when gathered and stored into our composite sheds is a prime ingredient for the successful cultivation of Heaths and all New Holland plants, and is of considerable importance to the well-being of the subject in hand.

White rock sand is, probably, the best of its class, as it can be broken down either larger or smaller, as the case may be, according to the size of pot and plant, and its particles are always of a gritty nature and capable of withstanding any amount of fatigue to uphold the physical character of the soil.

The mechanical operation of mixing the ingredients above named is a very simple one, and the potting of the plants thereafter is nearly as simple. It must be borne in mind, however, that the compost and the operation go far towards successful cultivation. The soil when mixed should be lumpy, without

being excessively so. If it is of the nature recommended above it will be sufficiently fibry to be elastic, and require to be somewhat firmly packed round the edges of the existing ball. If it is, on the contrary, so comminuted as to have little or no elasticity, no amount of care afterwards on the part of the cultivator will ever insure success, which clearly enough elucidates that its reduced power of admitting air, not to speak of other concomitants, is one of the chief causes of sickly subjects. In our own collection I have occasionally observed a sickly patient, and had him thoroughly sounded and reduced, probably from a nine-inch to a five-inch pot, furnishing him with a better diet and ample space for respiratory, absorbent, and digestive purposes, kept him close and under a subdued amount of light, which in course of time had a salutary and convalescent effect.

We would say to the amateur and all those who may take an interest in our dissertation, "Do not allow conventional rules and forms to interfere between you and your sickly Camellias, if perchance there should be any amongst your collections. Get to the roots of them at once as soon as indications of weakness are apparent, whatever time of the season it may be—summer, autumn, winter, spring; shake every particle of soil from the roots; introduce them afterwards into a smallish pot for the size of the plant; for although gallant-looking and glutinous as they may seem to the uninitiate, they are by no means gross feeders. If they have suffered very much let the compost be considerably more sandy, plunge in mild bottom heat if it can be had, at all events avoid currents of air, syringo overhead occasionally, which will be all the watering necessary for some time to come, and your patient may possibly recruit." Certainly most failures, at least that have come under my own cognisance, are attributable to clogged soil, ending in sour composts—composts that have scarce any organic matter, where water stagnates and refuses to evaporate in the one instance, or percolate through the drainage in the other, and hence causing a sickly and sluggish circulation of sap until, if unremedied, they pine away a miserable existence.

It is, therefore, of infinite importance to see that the various chemical ingredients are so constituted as to insure a healthy physical action, which simply means that in the first place they should be efficiently drained, that the mixture should be so open, the particles so disuniting as to admit a free and rapid passage both to water and air, and that the soil itself should be composed inorganically as well as organically, so as to afford decomposing matter to their roots in their active state of absorption.—JAS. ANDERSON, *Meadow Bank, Uddingstone.*

PRUNING FRUIT TREES IN POTS.

A FRIEND of mine, a medical man, being called to attend a person in a high state of fever, directed the nurse, amongst other things, to dip a piece of rag in vinegar, and apply it to the patient's head. Calling the next day, he was unreasonable enough to be very angry because the nurse, fearing to give the man cold, had warmed the vinegar. He had never told her not to warm it, and she thought it very hard to be scolded and called a stupid old fool. What a valuable work that will be on gardening which, in addition to plain directions for everything, shall guard against every possible mistake, and shall say on all occasions, "Now, don't warm the vinegar."

Some time since I sent a lot of beautiful Peaches and Nectarines in pots, full of blossom-buds, to a gentleman, and his gardener cut off pretty nearly all the branches. It was very unreasonable of me to be angry; so, for fear anybody should require to be told not to warm the vinegar, I will next time I write on orchard-house subjects say, that a fruit tree in a pot wants little or no cutting. If the end of the branch is removed there is, perhaps, no wood bud left; so let it put out, and stop the shoots when they have made a few leaves.

Talking of cutting, how trees would cry out against some gardeners if they had the power. Did you ever see a fine-trained wall tree leave a nursery that was not cut almost to pieces when replanted? I have, but not often. How astonished an intelligent tree would be to find an extra price had been paid for the pleasure of cutting him up. I have heard my father tell of a fine Bess Pool Apple tree that had often borne from twenty-five to thirty bushels of fruit in a season. A new gardener came to the place, caught sight of the tree, and exclaimed, "What a fool Brown must be not to have trimmed that tree; but I will let daylight into it." A saw was procured, some large limbs

were taken close to the bole, and the new gardener walked away well satisfied with his work. The next year the tree made a great deal of young wood, and never remembered to bear again till it began to decay where the large branches had been cut off, and it was in a few years cut down. It gives me a shudder to see a knife in some people's hands. Capt. Lawton, in Cooper's tale of "Spy," had not a greater horror of a saw.—J. R. PEARSON, *Chilwell.*

AN ECONOMICAL RUSTIC ICE-PRESERVE.

WITH the two excellent articles from the efficient pen of Mr. Beaton so recently before us, the same so scientific and practical upon ice-houses and ice-keeping in general, it may seem superfluous to add more to the same subject as it is not, as I intend this to be, a practical abstract upon the same or similar ideas. I think, from possibly a fallacious notion, many with less means at disposal than many of our wealthy aristocratic and mercantile millionaires entirely reject the idea of ice-keeping during summer from a supposition that it entails a prodigious amount of expenditure. Now, my chief object in writing this article is to combat this idea, and endeavour to explain how a block of ice might be prepared and kept at a very trifling tax in a pecuniary point of view. To abandon generalising I will endeavour, as an unanimous correspondent, to explain how to construct my rustic ice-preserve.

Select a spot, if possible under trees, and upon the base of an abrupt slope in the ground falling some four yards in ten. The object in the selection of this peculiarity in the ground is bifold—you insure a natural drainage from the fact of the ground being lower, upon finding its own level, than the table land you make, upon which to pack your ice. This essential level should be raised by pecking out a piece of the bank, or, better, made up with waste stones. Again, in this way, independent of the natural drainage, you easily form an effective water-and-air drain from beneath the centre of the ice, through waste stones, to the level below. You perceive, I would elevate rather than sink; and this, for better preservation, I might triple. The advantage of this slope—if approachable, which it should be, is that you may tip your load from the level above, and it will slide down into its bed at once without any manual labour whatever—a very essential object when you want to secure all the hands possible for loading, carting, breaking, with many ceteras in the usual *modus operandi*.

The size of this tenement of an offspring of winter depends entirely upon the quantity desirable to be preserved, excepting in one material point—namely, thirty fair-sized loads are the minimum in quantity I could advise any one to start with. The combined influence of eighty loads has its preserving powers quintupled in comparison with my smaller quantity.

Well, presuming we have the bed, drain, &c., prepared, our next two heads are protection from wet, and wherewith to neutralise the air.

The means to so neutralise the air. To filter it is equally applicable—an expression possibly unrivalled in singularity this year. Yet why may not the moisture from one of those close muggy days, which wastes 50 per cent. more ice than the hottest week in summer as it penetrates to your ice, be detached? I will but explain the simplest modes, with the more economical way, wherewith to place this straw, the desideratum being to form a wall of the same some 2 feet wide. If the quantity to be preserved is from thirty to forty loads, as above, four posts should be plunged perpendicularly into the ground, for the double object of forming the place, and more particularly supporting the thatched roof. They should be so placed as to form an interior of 9 feet square; the height of the same should be 9 feet also. Not to trespass upon this interior, a row of hurdles should be placed round the three ends, to be enclosed, stood on end, properly supported. Two feet from these outside, should be placed another row of hurdles in precisely a similar way. Between these place the straw, and behind it any old thatch will do; it must be well trodden and rammed down. The thatch should be placed beyond this that it may not become wet. A vacancy of at least 1 foot of open space all round between the aforesaid thatch and the top of this straw wall should be left, to admit of a draught passing right over the mass.

At last we come to the filling. If, as above, you tip it from the cart direct into its bed I consider it is preferable to have the first layer placed in the way you would floor tiles. Indeed, I have

a great leaning for quite a fresh way of housing ice—namely, packing the whole of it in this way layer after layer. Presuming you could command such an unheard-of thing as an ice-crusher, with which to break the ice small as candied sugar, after each layer to throw a broomful on, and sweep it into the crevices; and to provide if the little extra time would not be amply compensated for.

The mode of housing has received such efficient elucidation by other pens than mine in this Journal to need no further comment by me. I will refer to two great destructives used by some to assist in breaking the ice, or, rather, melting the same—namely, hot water and salt, the former more especially in severe frothy weather I believe is advantageous. Of the latter's merits, theorising places many objections to it in my mind; for I fear it will always have when thrown a moistening power, more especially when thrown among so active an agent as the subject of my remarks. It is possible, after the first slight or partly effective thaw, the place should, if the weather proved frosty, be thrown right open. When the weather again breaks, to be effectively covered over with at least 2 feet of straw; the best of what straw being placed immediately over it. I filled a similar place to this with sixty-five loads on boxing-day, 1859, and with the use of three or four wheelbarrows per week, with an unprecedented hot summer, supplied the last of the same to ice the noble vintage wines consumed in the establishment on New Year's-eve, 1862. This from choice only, as we have an excellent ice-house, the child of past-conceived ideas, upon the rusty-hinged door of which, so illustrative of its usefulness, by a rustic typographer, is the following—

"Last filled in '57—

The same a useless job has proven."

Would that it were a little nearer home it would make a very excellent potato-house.—W. FAWLEY, *Digsweil*.

GROWING MANGOLD WURTZEL SEEDS.

SOME years since I was talking to one of our best growers of Mangold Wurtzel (C. Paget, Esq., of Roddington), when he made the remark, "I wish the seed-growers would sell Mangold seed which would not produce runners." I argued it was not their fault, as they could not save seed from runners as he appeared to think—at any rate, not in this country, as it would not ripen. Experience has led me to alter this opinion, not that I think the evil is caused by saving seed from runners, but by setting late-sown plants for seed. Having selected large fully-developed roots of a new kind for many years I have found the tendency to produce runners lessened each season, till last summer there were only about a dozen in six acres; and I have heard the remark made by a good Lincolnshire farmer that a new variety always produced less runners than an old one. How is this? It appears simple enough to me now. The Mangold is a biennial; it is its nature to grow one season, and produce seed the next.

A good crop of well-grown Mangold is here worth £20 to £30 per acre—a large sum to risk in addition to all the expenses of a second year, and that to produce so uncertain a crop as Mangold seed which in a wet summer may never come to perfection. The growers, therefore, sow seed in August, and plant the roots (then about as thick as one's finger) in the autumn. If well covered with earth these are safe in an ordinary winter, and will produce as much or more seed than large roots the following year. Is not this making the Mangold almost an annual? And is it a matter of surprise it should show a tendency to go to seed when reason? Let seed-growers produce a good article, charge a fair price, and the farmer would be the person most benefited.—J. E. PEAK-OX, *Chilwell*.

STREPLY OF ICE IN PARIS.—Since the frost has set in with such constancy in Paris more than 1,000,000 kilogrammes of ice have been removed from the lakes in the Bois de Boulogne, and deposited in ice-houses established by the Municipal Council of Paris. Previous to the foundation of these ice-houses, the supply of ice requisite for the population of Paris was monopolised by two companies, one of whom collected their ice at St. Ouen and Gentilly, and the other at Villeneuve-Petitang. The consumption of ice in Paris amounts to 6,000,000 kilogrammes in the year, which is sold at 9c., 10c., and 11c., the kilogramme to the retailers, and resold by them at 20c. and 30c. the kilo-

gramme, according to the heat of the weather. The object of the Municipal Council in establishing their ice-houses was to prevent the monopolists from increasing the wholesale price of ice, and to diminish the retail price by selling it at 12c. the kilogramme. Each kilogramme of ice pays a duty of 6c. on entering Paris. The city, consequently, gains 6c. on every kilogramme of ice consumed in Paris, and the greater the consumption the greater the addition of the revenue of the city. The duty on the 5,000,000 kilogrammes annually supplied from the municipal ice-houses amounts to 300,000c. The ice-houses established by the Municipal Council are situated in that part of the Bois de Boulogne comprised between the fortifications and the Auteuil Railway, not far from the lakes of Passy. The excavation for the formation of the ice-houses is 70 yards long, 30 wide, and 15 deep. This immense area of 72,550 yards is divided into ten chambers, capable of containing each 1,000,000 kilogrammes of ice; but, as the waste is estimated at 50 per cent., the ten chambers supply but 5,000,000 kilogrammes. These chambers are vaulted, and are covered with earth to a depth of 1 feet. Large storehouses are erected over the earth to prevent rain from penetrating into the ice-houses. The ice is conveyed to Paris in baskets containing 30 kilogrammes, so that 25 kilogrammes may be found on delivery, the waste on the journey being estimated at one-sixth.—(*Times*.)

CULTURE OF YUCCAS.

A *Very Old Subscriber* would be thankful for a few directions respecting the treatment of Yuccas. Two were given to her three years ago. One bloomed finely the summer before last and died. A small plant has since come up near where it grew. What should be done with it? The other bloomed last summer and still lives. Three or four suckers have come up round the old plant. Should they not be removed?

[The sucker rising from the roots of the dead Yucca will make a better plant than the parent one. Let it be as it is, unless you could give it some good surface soil, and then mulch it, more for the purpose of encouraging the roots to come near the surface than to hold in moisture. All Yuccas send wiry, long roots down no one knows how far, till at last down goes the plant itself, and it is discovered the cause was from the roots getting into cold soil without drainage. Then, as precautionary measures, gardeners make very good surface soils for their Yuccas, and mulch the plants while they are young. They also choose the driest situations for them, and never trench or dig the ground for them so deep as they do for any other plant. The way they do with the suckers is to leave them on a year or two, or more, or only one year, according to the size, then taking them off very carefully, with or without roots, as it happens, at the end of April; they then stick them in in light soil to root in for a year or two, then up with them and plant them out for good in some upland place.]

CUTTING DOWN OLD LEAFLESS HOLLIES.

MY HOLLIES stand exactly in the same predicament as "AN OLD SUBSCRIBER" describes at page 257. That the frost of the last dreadful winter was the cause there is not a doubt, as all our Hollies and Laurels, Bay, as well as Portugal, wherever situated, and even common Ivy, have all shared a like fate. As every rule has at least one exception, so with the Hollies. Some twenty years ago, the old Limes of our avenue were necessarily thinned by the removal of every alternate tree, and evergreens planted in their stead. Now it so happened that one of these, a common Holly, never lost a leaf, while its nearest neighbour (only a Lime between) of the same sort and size, and sheltered exactly alike with every common and variegated one about the place, did not retain a single one. How can this be accounted for? and would it avail propagating off this hero, the best time, and how?

There are two Hollies in particular as to whose condition I would especially solicit your valuable advice. They occupy the points of two flower-beds before the house, are forty years old, variegated, one golden, the other silver (hedgehog variety), and being handsome pyramids I should regret very much to lose them. Till last winter they were very healthy. The leaves all dropped off in the spring, and there was no appearance of vitality till midsummer, when there appeared little shoots from

the main stems and branches, the twigs completely dead. It is my intention to cut back all the branches to the main stem, with the hope of their yet recovering, and postponed this operation till spring, thinking, that if the young shoots were exposed this winter before being hardened, they too would perish. Would you kindly say if this plan would have a prospect of success, or should I cut them down to the surface? In that case I suppose I should select the strongest shoot, and remove the rest the first season. Can you also inform me if the wood of those frost-killed Hollies would be equally serviceable for every purpose with those cut down in the ordinary manner?—A MODERN SUBSCRIBER.

[There is no remedy so sure for frosted Hollies as cutting them down entirely to the surface of the ground; that is to say, when the trees have been entirely frosted and seemed dead for a while, and then sprouted also on the bark. If they were very large trees we would give them two years' chance, and if they got sufficiently clothed, good; if not, no remedy will do. We have never known a single instance during forty years where a Holly got crippled from any cause, and more especially from frost, that it recovered itself like most other trees; and we are quite sure no tree recovers faster from being started afresh and kept to one leader after the old head was gone.]

A FEW DAYS IN IRELAND.—No. 11.

(Continued from page 312.)

KNOCKMAROON LODGE.

THIS picturesque spot, the residence of Gilbert Burnes, Esq., is situated on a steep bank of the Liffey, not far from the Knockmaroon Gate of the Phoenix Park. Immediately outside of that gate three roads diverge, one leading to the small village of Chapel-rood, some five hundred yards distant, one to Castle-nock, and the third going to the pretty little town of Lucan, with the celebrated steep slopes of Strawberry-beds on the right and the Liffey on the left.

Fig. 1 will give an idea of the position of these beds, which occupy a space of about sixty acres Irish, and more than ninety statute acres, and are looked upon as a kind of Dublin institution. These banks are divided into holdings of from two to six acres. Mr. Pressley, the able gardener of Knockmaroon, informed us that the kind of Strawberry chiefly cultivated is called the Chinese—a rather inferior pale colourless kind, but which still brings remunerative prices in the market. Many of the best varieties have been tried on these slopes, but without much success. Many of the best kinds are, however, successfully cultivated in low flat lands of the locality. The cream of the Dublin market for the best kinds of early Strawberries has, of late, been taken by the growers near Cork, where the fruit ripens earlier than around Dublin.

As already intimated, the bulk of the crops from these banks is sold in the city; but on the Sunday afternoons of July and August, vast numbers of people resort to the banks, and plenty of licensed public houses being open after two o'clock P.M., scenes are sometimes enacted that would not be so likely to occur if the visitors could be satisfied with the fruit, or even with dishes of Strawberries smothered with sugar and cream.

Near the Phoenix Park gate is a pretty Elizabethan lodge built with granite, the entrance to a gravel walk 550 yards in length, and communicating with the residence, having a wall covered with Ivy on one side and a line of Elms and Chestnuts on the other side of the walk. Close to the lodge some good-sized Hollies, Arbor Vites, Laurels, &c., had been planted last April, but owing to watering, syringing, and shading in the middle of sunny days, the trees have all done well, and now scarcely present a sign of being transplanted.

A few hundred yards from this on the road leading to Chapel-rood is the carriage entrance, the gates and palisading being in the form of a curved-in semicircle. A massive pier or pillar stands on each side, and in front of each pier in line with the roadway a handsome Chestnut tree. The lodge is plain, substantial, and commodious. The new house being built is also distinguished for simplicity and elegance. The blocks of granite, however, lying in every quarter, with stones, bricks and mortar, earth-heaps from foundations, lining out terraces, building their walls, with an open trench all the way to the river, along with masses of wood of all sizes and shapes, for wall-plates, ventilators, and

rafter sash-bars, &c., all prepared so as to secure economy, efficiency, and substantiality, all presented to the eye of a stranger such a melley of intricacy, instead of the fine plants he was told he should see, but which under such circumstances were huddled into corners to keep them out of the way, that it would have required at least half a day of Mr. Pressley's time to enable us not only to obtain a clear idea of all that was intended, but to carry away with us a picture of what it would all be when finished. Our readers may have less regret on this account, as Mr. Pressley, whose contributions have already appeared in these pages, has promised to give us a full account, and especially of everything connected with the new houses as soon as the works are concluded.

How slight often are the means which almost unconsciously give a tone to our actions and our feelings! One philosopher may contend earnestly, that man with all his vaunted powers is the mere creature of circumstances; and another may argue as zealously that a man is really not worth his salt that could not bend circumstances to suit the purposes of his iron will. After all, however, the stubborn facts will remain, that whilst to a limited extent we may control and master circumstances, these circumstances, nevertheless, will greatly influence our conduct and our thoughts. Thus for years we had thought but little of Thomas Moore and his poetry, but the sight of the statue erected to his memory in College Green at once brought vividly before the vision of our mind many of those sweet melodies in which he sung of the beauties, and prophesied the greatness of Green Erin—the melodies which delighted us even more than the withering sarcasm with which he assailed all that he deemed opposed to his country's weal. Would that such a statue, instead of standing in a museumised thoroughfare, had been surrounded with those beauties of Nature the poet loved and could describe so well.

Here, again, as we stood on this picturesque spot, the name and lineage of the owner seemed to bring before us the described realities of a certain Saturday night, the scene of parting with Highland Mary, the breathing of the independent ode, "A man's a man for a' that," &c., until passing on from the home at Ellisland, we seemed to get a view of the moor farm of Moss-gill, where a noble-hearted sire with horny hands and aching limbs undauntedly and perseveringly contended with a poor soil, an inferior climate, bad seeds, bad seasons, bad crops, and yet never gave up, because, if possible, possessing a keener sense of honour and manly independence than even distinguished his more gifted brother, the great poet of Scotland. But for showing too much of a prying inquisitive spirit into what belongs to the affairs of private life, it would have been interesting to know, by what control of circumstances, or by what merely being guided by circumstances, the son of such a sire and the nephew of such a poet-uncle, came to hold the position of one of the principals in the great mercantile firm in Mary Street—came to be recognised as a man of refined tastes and liberal benevolence, a patron of the fine arts, an enthusiastic supporter of everything connected with gardening, and finally to be the owner of this beautiful place, where those who carry out his wishes speak of him less as a master, or employer, than as a kind-hearted sympathising friend.

Following up the same train of thought, it would not only be interesting, but useful to know the controlling circumstances and the guiding reasons that led to the choosing of this picturesque bank as the site for a new mansion, and the position for a new terraced garden. Besides the making of these terraces, the sight of large and lofty mills in the foreground would have been considered objectionable by many; and more especially when another site just across the road might have been chosen for a mansion and an ornamental garden. This ground, consisting of a somewhat level platform of about two acres, has some fine specimens of deciduous and evergreen shrubs and trees along a drive, and some good specimens of the Pinus and allied tribes in groups, and, no doubt, will now have more. A broad bridge over the public roadway will connect it with the new mansion, it being intended to make the bridge itself into a kind of garden entrance-hall. The simple fact of the fine Wellingtonia having been planted in a temporary manner led us to think that there had been some little consideration before the site of the mansion and the richest part of the ornamental grounds were finally decided on. The present arrangement will combine the advantages of both positions.

For a man engaged in the weighty anxieties of a great business

no more fitting retreat could be found. I have no sympathy with those who, like the elder Repton, would plant out a fine view because the sight would remind one of the struggles and difficulties of the past part of a life, or the trying business avocations of the past day. Still the mind needs repose, and complete change of occupation and of object is often the best restorative rest that can be given. To obtain that complete change, there would be no necessity for planting out a single object whilst examining the matters of interest on this platform. The owner, though only a short distance from Dublin, hears and sees no more of it than if he possessed a mansion amid the fastnesses of Wicklow, or the wilds of Connemara. Even the views are refreshing; peeps through the trees of the Ivy-covered tower of Chapeloid Church; the fine spire of the church of the Royal Hibernian Military School; the Whin and Bramble slopes of the Phoenix Park, instead of the picturesque banks where the terraces now are; and though from a mansion placed well back on that platform, the eye would pass over the Liffey rolling in the valley in front, it would pass over the top of the mills as well; whilst from several points and vistas the river could be seen in the distance, clear and silvery as mirrored lakes.

Before leaving this ground we must notice a fine Wellingtonia now 11 feet 5 inches in height, a most interesting account of which will be found at page 42, in the April 17th Number for 1860. A small plant was procured early in 1855, it was 9 inches high when transferred to a site 5 feet in diameter, well dug, and supplied with good soil, in March, the place being very exposed to test its hardiness. In the autumn of 1857 it had attained the height of 3 feet 6 inches; in the following summer it made only 11 inches of a leader—a proof that it had passed the good prepared soil. In February, 1859, a trench was taken out 20 feet in diameter, and 3 feet deep. Commencing at the outside, and carefully preserving the roots that had passed the five-foot circle, and replacing them in the new soil, consisting of turfy loam two years old, and two barrowloads of bog earth to each cartload of turfy loam. In that summer (1859) it made a leader of 22 inches. It is now the above height 11 feet 5 inches, and this summer made a leader of 2 feet 9 inches, and was of a beautiful colour. Mr. Pressley intends to give the plant the benefit of another trench when it needs it. We should like to know now the height of the fine plants at Bicton, when we noticed some years ago. Mr. Barnes had placed his plants on large mounds, resolving to widen the mounds as the roots got to the outside. We find at the page referred to, that Mr. Pressley had recommended to Her Majesty's Commissioners the planting of four of these fine plants at the four corners of the Wellington testimonial, and if far enough from it nothing could be more suitable.

We noticed, also, handsome, healthy specimens of *Picea pinsapo*, *P. Nordmanniana*, *P. Jeffreyana*, and *Pinus muricata*, bearing cones; nice plants of *Cupressus Lawsoniana*, *Thuja borealis*, *T. gigantea*, *Pinus Sabiniana*; a fine, dense-foliated specimen of *Cryptomeria japonica*, 14 feet in height, and a fine specimen of *Cryptomeria japonica* Lobbi, taller, greener, and denser in habit, and having every appearance of being harder than the common variety. *Cupressus Lambertiana* and *macrocarpa* planted in 1853, then 18 inches high, are now 26 feet in height, and of proportionate diameter. The first-named variety here sends forth its branches almost horizontal and flat, and then droops every point like a Decodar.

The impression on our minds from a first and hasty view was a kind of lingering regret that this snug spot was not chosen for the mansion; but we soon felt convinced that it could have stood no comparison with that adopted for combined artistic and picturesque effect. What, if the mills come in, to remind one of the busy activities of life? Many would rather like to be so reminded, and feel delighted even by the greatness of the contrast. Those who dislike all violent contrasts may either plant out the view of the mills altogether, or block out so much of them as to make them lend an additional interest to the picture.

The sectional lines of the terraces and slopes are drawn to a small scale to get them in the page, but the figures will show their width and the height of the walls. The level of the first terrace in front of the mansion is 80 feet above the level of the river. From these terraces and the mansion fine views are obtained of the distant Dublin mountains, and about midway the fine, tall chimney of the Great Southern and Western Railways' works at Inchicore. Part of the opposite bank of the Liffey belongs to Mr. Burns, and may also be rendered pic-

turesque. The terrace next the mansion, and the one below it, will be turf, and bedded in the picturesque style. A Yew-hedge

probably will be planted at the back of the wall of the second terrace, to break the view of the mills. Trees will be planted in the meadow, which averages 300 feet in width, to promote the same result. In front of the second terrace-wall a new range of glass houses is in course of erection, 170 feet in length. The two centre houses will be span-roofed for Orchids and stove plants. To the right and left of these there will be lean-to houses for forcing fruits and flowers. These terraces are all level from east to west, and the floors in these houses will all be on a level—a matter of great importance for proprietors and visitors passing through them comfortably. The wide slope of 70 feet below the glass erections will be planted with dwarf fruit trees in lines up and down the bank, north, and south. These trees will be a fine, distinct feature when in bloom and in fruit.

Showing terraces and slopes, the width of which is marked; also the mode of obtaining water, by working a wheel and pump, by means of water from the tail stream of a mill.

- A. Pump-house.
- B. Mill stream, dotted line showing opening to pump-house.
- C. New tail stream from pump-house.
- D. Broken line, representing 300 feet of meadow belonging to Mr. Burns.
- E. Dotted line, two-inch pipes up the bank to the mansion.

The position of these terraced gardens will at once show the importance of plenty of water. Previously there had been much scarcity, though every roof had been used to catch all that fell on them. An ample supply is now obtained from the river, and that by a mode so simple, and yet varying so close on the impossible, that very few would have dared to attempt it. There is no difficulty in turning a water-wheel when a head of water can be had, or there is a good brisk flow in the stream; but there were none of these accessories in the present case. We could see Mr. Pressley was very anxious on the subject, and had considerably difficulty in making a new tail race from the pump-house through Mr. Burns' meadow, the fall in 200 feet not averaging more than 6 inches. The tail stream from the mills passes between Mr. Burns' ground and the river. At a curve in that stream, a fresh side being made, an opening was taken out, represented by the dotted line at D, to act at once on the water-wheel at A. This curve is about 100 yards from the

mills. No weir could be placed across the stream, because that would have raised the water on the mill-wheel above. There is nothing, therefore, of what is called a head of water—motion to the wheel is entirely dependant on the flow of the stream from the mills in its course to the river. The force of this may be estimated from the fact that from the wheel to the river there is only a fall of 6 inches.

The wheel is 9 feet in diameter and 3 feet in width, makes an average of six revolutions per minute, and works two double-action pumps. Mr. Pressley informs us that since the middle of November these pumps have thrown on an average three gallons per minute to the upper terrace—a height of 80 feet and a distance of 500 feet. A large cistern is to be made 30 feet higher, so that the height then will be 110 feet. A two-inch metal pipe is brought in a trench from the pump-house right up the bank. Our new friend, who had many difficulties with the new tail stream, &c., must have experienced a great satisfaction and felt a load of responsibility falling away from him when wheel and pumps did their allotted part so nicely. The great credit of the success consists in the obtaining such a motive power, and that from water moving so slowly as to be next to stationary.

What with abundance of such water, the growing interest in the fine specimens on the upper platform lawn, the beauty of the terraces, the combination of the rare, and the lovely, and the useful in the new and older glass houses, the associations of healthy fruit trees in all their varied stages; and what from the clear water of the Lifley reflecting alike sunbeam and moonbeam in the valley below, we feel but too well assured that the liberal proprietor, and the kind, energetic gardener, will have to exercise even a still greater amount of their indulgence in coming years, in order that they may have the privilege and the pleasure of enhancing the delights of the true lovers of the beautiful. R. FISH.

PRUNING THE MORELLO CHERRY.

This tree, like the Peach, produces its fruit upon wood of the preceding year's growth (see *fig. 6*, in which *a* is a one-year-old shoot, and *b* a two-year-old one). It is always trained in the fan shape, and as the object is to have a full and regular supply of shoots in all parts, our directions for the Peach fully apply also to this. The Morello Cherry produces plenty of wood, which must not be laid in too thickly, if fine fruit is desired. This fruit is sometimes cultivated as a standard, and we remember the late Mr. John Wilmot, of Isleworth, showing us an orchard of this kind, in which the trees were annually pruned to give an abundant supply of young wood, by cutting away a portion of the older branches. The trees so treated produced large crops, which would bear comparison with the other fine products of this well-known and successful cultivator. Mr. Rivers recommends working Cherries on the *Prunus Mahaleb* for miniature trees, and such must be beautiful objects for an amateur's garden, and not unworthy of having a small wire cage to protect them from birds. We remember to have seen, at Hylands, in Essex, a large garden of dwarf Cherries covered over with wire. Like the Apricot, the Cherry is very susceptible of injury from large wounds of the knife; they are, therefore, to be avoided, by the timely removal of superfluous growths.

THE GOOSEBERRY.

When young Gooseberry trees are purchased they are often found with large aggregations of suckers about the stems, which not only rob the tree of nutriment, which should be otherwise appropriated, but are a plague to the cultivator during the whole existence of it. All this may be avoided by proper attention to the first formation of the plant when in the state of a cutting. A young shoot, 15 inches long, may be chosen and cut smoothly across at its base, cutting all the buds cleanly out except the three upper ones, which are intended to form the future head. This will give a clear stem of 1 foot in height, from which no suckers will ever arise (see *fig. 7*, A). We urge attention to this point from having seen it so much neglected. The three buds *a a a* at the top of the cutting will each produce shoots, which in the following winter may be shortened to three or four buds; these in the third year will form the skeleton of the future tree, as many being retained as circumstances and the judgment of the pruner may dictate. A well-formed Gooseberry bush should resemble a basin in shape, and stand upon a clear

stem or pedestal of 1 foot in height, for the purpose of keeping the fruit free from the splashing occasioned by heavy rains, which, without this precaution, would spoil much of it. All the branches should radiate from a common centre, neither crossing nor crowding each other.

Fig. 6.

Fig. 7.

The fruit of the Gooseberry is borne upon the young wood of the previous year, as also upon spurs along the older branches (see *fig. 7*, B, in which *a* is young wood, and *b b b* older spurs). One great point of good management is, therefore, to provide a succession of well-placed bearing shoots, gradually removing the old and enfeebled branches. It is well to shorten the points of the young shoots a little, as it prevents them from becoming naked of spurs at their bases, which they are apt to do, the sap always flowing with greater force to terminal buds than it does to those which are situated lower down. Gooseberries are sometimes trained with tall single stems and weeping heads, or open basin-shaped ones, and sometimes as pyramids. Pretty and interesting as are these forms, they may be considered rather as ingenious displays of artistic skill on the part of the gardener, who has ample means for its development, than as really useful or remunerative in a superior degree. And then we do not find them adopted either by market gardeners or prize Gooseberry-

growers. Sometimes this fruit is trained upon a wall, and for this purpose we think vertical training the best form. Where the fruit of the Goose-berry is gathered green for bottling, or for jars, the trees may be left thicker of wood than where it is intended that they should perfect their fruit, and *vice versa*.

In shortening back old branches care should always be taken to cut to a rising shoot—*i.e.*, one whose tendency is to keep the tree upright rather than to bring it to the ground. The produce of trees thus managed will always be plentiful and good, and the advantages of order and method be as apparent in cultivating this humble fruit as the results of our advancing knowledge are evident in the higher departments of fruit culture.—H. BAILEY, *Gardener, Nuneham.*

NEW BOOKS.

THE ROSE ANNUAL.—By the publication of the "Rose Annual" Mr. Wm. Paul lays the Rose growing world under an obligation by his spirit and enterprise. Knowing something, as we do, of the getting up of such a publication, we are aware at how much loss it must be accomplished, and that only his desire to keep his friends and the public in general well informed on the subject could induce him to continue it. The four Roses selected for portraiture this season are Beauty of Waltham Cross, a seedling of Mr. Paul's own raising; Marquise de Foucault (Tea) and Souvenir de Comte Cavour (H.P.), both raised by Monsieur Margottin; and Catherine Guillot (Bourbon), raised by Guillot of Lyons. They are executed in Mr. Andrews' best style. *Beauty of Waltham Cross* received a first-class certificate from the Floral Committee of the Royal Horticultural Society, where we had the opportunity of seeing it; it promises to be a useful hardy Rose of the Jules Margottin type, of which fine Rose it is, indeed, a seedling. Its hardiness was proved by the fact, that it withstood out of doors the trying ordeal of last winter. *Marquise de Foucault* is stated by Mr. Paul to be a comparatively old Rose, having been raised in 1854, between Stroncho (T) and Mrs. Bonquet (B) (query China?) In 1855 it was nearly lost, and hence has not been let out until last season. Mr. Paul considers it will be best suited for pot-growing. Thus two old Roses in this section came out this year, the present, and l'Enfant Trouvé. The figure of Souvenir de Comte Cavour does not do that flower justice; and either the bloom from which it was taken was an inferior one, or else it was reproduced from a French drawing. From what we saw ourselves of the flower we agree that it will prove to be one of the best of the forthcoming brood; but the petal is more shelly, and the flower more cupped than in the plate. Catherine Guillot, too, underrated that exquisite flower. As it was, Mr. Paul says, taken from a small bloom, we are quite sure this flower will take very high rank amongst its fellows in the same class.

Mr. Paul gives a very interesting summary of the events of the annus memorabilis 1851-62, the most destructive yet we believe likely ultimately to be one of the best for Rose-growers ever known. He rightly attributes the past destruction of Roses, and indeed of all things, not only to the frost, but to the exceedingly unripened state of the wood, and considers Rose-growers need not be discouraged. It will, we believe, have cleared our gardens of many useless flowers, and led to a wiser introduction of newer and improved varieties. In the favourites of 1861, he enumerates about twenty-four as likely to be valuable varieties, giving the palm to Catherine Guillot, Duc de Cazes, General Washington, Madame Furtado, Princesse Mathilde, and Triomphe d'Ameins, and condemns, as we have, Reine des Violettes. He then enumerates the various Rose shows, and gives a useful list of the number of times each Rose has been exhibited, from which we gather that the most numerously exhibited Roses were Comtesse de Chabrilant, General Jacqueminot, Lord Raglan, Madame Knorr, Madame Vidot, Victor Verdier, and Gloire de Dijon. Finally, he gives us a chapter on the forthcoming brood, and descriptions of eighty, warning us at the same time against the notion that we are to take the owner's description of them as correct. In fine, we can honestly say, that there is collected here much information on the subject of Roses, old and new, likely to be most valuable to all who take an interest in the queen of flowers. An advertisement on the cover announces a new edition of Mr. Paul's "Rose Garden."

This we think is a move in the right direction, and the experience of the past ten years will, we doubt not, be ably brought forward in his new work.

WORK FOR THE WEEK.

KITCHEN GARDEN.

DURING weather like the present a number of operations may be proceeded with which are generally deferred to the spring. Ground should have the necessary turnings to bring it to a friable state by the time that it will be wanted for spring cropping. *Asparagus*, a heat of about 55° should be maintained in the beds; if things are necessary, a narrow one entirely around the bed is preferable to a broad one, or a portion only, as a strong heat is not necessary. *Beans* and *Peas*, protect those that have made their appearance above ground, either by covering with light dry soil, or by sticking on each side of the row small boughs of the fir, or any other evergreen. Sow a succession in the open ground, and between the rows of *Peas* try a row of round *Spinach*. Follow up with energy and system the hoeing, surface-sirring, and dusting among advancing crops. Destroy mice. *Mushrooms*, the beds to be made as wanted, using a portion of fresh turfy loam with the droppings. *Onions*, the ground intended for them would be benefited by a top-dressing of well-decomposed rich manure, which should be forked in and well knocked about on frosty mornings. *Potatoes*, a quantity may be put together in a box and covered with soil, and the box placed in heat; this will cause them to sprout, and forward them considerably for planting in the hotbed. Make small hotbeds for sowing *Radishes*, and *Early Horn Carrots*, *Cauliflowers*, and *Walcheren Broccoli*, *Lettuce*, and various other things which will be found useful in the spring if the autumnal sowings should fail. Sow a small batch of *Celery* for the first crop on a slight hotbed. *Cress* and *Mustard* to be forwarded as usual.

FLOWER GARDEN.

Any alterations that may be on hand, involving the removal of a considerable bulk of soil, cutting walks, or anything which can be judiciously done now, should be pushed forward as expeditiously as possible, in order to have the hands at liberty for the ordinary routine of spring work, which will soon be demanding attention. Deciduous trees and shrubs may now be thinned out and pruned, if such is required; evergreens, however, had better remain untouched for the present. Planting, too, should not be done, except in extreme cases, at this season. The *Hollyhocks*, planted in borders are very liable to the attacks of slugs, which greedily feed on the fleshy roots; a dusting of soot occasionally will make them less palatable.

FRUIT GARDEN.

The general pruning and training of wall trees and espaliers may be proceeded at all times, except during severe frost. *Appricots*, *Figs*, *Peaches*, and *Nectarines* are, however, better left for some time to come. *Goose-berreries* and *Currants* planted in rows 10 feet apart, and trained as low espaliers will bear well and economise space, as vegetable-crops of various descriptions can be advantageously grown between the rows. Newly-planted trees of all kinds to have their roots protected from frost by a mulching of short litter or dung. Prune Vines out of doors without delay. Cut out the old wood from *Raspberries* and the canes not wanted for fruiting. Replace decayed stakes, and tie to them the canes neatly; small twigs of any tough willow are generally used for the purpose. Dress with light manure, and dig the ground between the rows. The pruning and thinning of trees in the orchard may still be continued.

STOVE.

Some of the plants that have commenced their growth may require shifting. A portion of the stock of *Gesneras*, *Gloxinias*, and *Achimenes* may now be plunged in bottom heat to start before potting them. As the principal kinds of *Begonias* will now be showing bloom, they should be staked carefully, to preserve their fine foliage from being damaged when removed, as they may be, if required, to adorn the conservatory. Still be cautious in the application of more fire heat to *Orchids*; it is far better, the season being early, that they start somewhat later with a free growth than to make a premature and feeble one. Care to be taken that a due proportion of moisture is maintained in the atmosphere; although the majority require to be dry at

* *The Rose Annual* for 1861-62, by William Paul, F.R.H.S., author of the "Rose Garden." London, Kent & Co., Paternoster Row.

the root during their rest season, nevertheless, they require a moistish atmosphere when in a state of motion.

GREENHOUSE AND CONSERVATORY.

Although it is not advisable to shift the general stock of greenhouse plants for a few weeks to come, nevertheless, under some circumstances, a few plants may require fresh potting. Many softwooded plants require to be headed back, or pruned, at this season, and require a sufficient time to produce shoots an inch long before they are in a fit state to be repotted. Attend to the training of Tropaeolums and other climbing plants on wires or trellises. A forcing-pit is indispensable to keep up a regular succession of Tulips, Hyacinths, Narcissi, Cytisuses, Azaleas, Cinerarias, and other such early-forced flowers as may be required at this season. Care to be taken that Camellias receive no check, or their buds will be endangered. It will be necessary to examine softwooded plants, in order to remove decayed leaves, and make an arrangement that will give them liberty to receive the full benefit of light and air. Turn over and prepare compost for Pelargoniums.

FORCING-PIT.

Bring in a successional lot of bulbs: it is presumed that they have been potted for some time, and that the pots are full of roots, when success may be expected to follow; but if they have been lately purchased and potted they will not bear the excitement of forcing. In all such cases several weeks of root-action are necessary before they are fit to be subjected to the application of heat. Pinks, after they have made a little growth, require to be removed to a cooler place, or the buds will fail. Gardenias require a warm moist atmosphere, which may be slightly increased if they exhibit activity. Get all the hardy forcing plants, if not already done, under the protection of the greenhouse stage, or any other such place protected from frost; it is also advisable to excite them gradually before they are introduced to the forcing-pit. Temperature of the forcing-pit to be from 60° by night to 75° by day with sunshine, to shut up early with a moist atmosphere; but a little air to be given, unless the external cold is very severe, before leaving the fire for the night.

PITS AND FRAMES.

The stock of bedding-out plants should now be looked over, and if the quantity of some sorts is too limited for the demand at bedding-out time, a portion should be removed into a warm house to produce cuttings for propagation. It is, however, advisable that bedding-out Geraniums and other such plants should be well established, and of tolerable size, before they are transplanted to the open bed, as fresh-struck plants of such are apt to grow too fast and bloom late in the season. As severe weather may now at any time be expected, a good supply of litter should be in readiness for extra covering if required.

W. KEANE.

DOINGS OF THE LAST WEEK.

In our last week's gossip, near the end, the words "Robin alone in it" should have been "Robin alive in it." I just mention this for three purposes. First, to thank the printers for deciphering so well my hurried writing, as well, if not better, than I could do myself if I had the manuscript ten days after it was written: I fear it is a besetting sin with me. When a correspondent's letter comes in my way that I have to con over and over, perhaps a dozen times, before I can make out the meaning clearly, I just try and place myself in the situation of the printers, and, for a bit, don't I write plain and legibly, every i dotted and every t crossed, and stops all right, &c. But, heigh ho! a hurry comes, and the pen cannot more a quarter fast enough for the words that are clamouring for room; and, I fear that many little errors are entirely the fault of the writer. Then, secondly, I want to impress on the minds of correspondents, writing to the Editors for information, the importance of writing legibly, and not to cross or interline their letters with small scratching, that it requires a microscope to make out; but to think that if their eyes are young and good enough to see a pin on gravel 10 yards off, other folk's eyes may not be so good as theirs. And, again, to write the words fully, and not leave us to judge what sd and th— are intended to mean; we would far sooner have "no heed" for "no end," and misspelling in abundance, though the sooner all gardeners spell well the more delighted we would be. If information is desirable, it is also very desirable that the persons willing to give it to the best of their ability should have as little trouble as possible in finding out what is really wanted.

These remarks do not, by any means, generally apply. Gentlemen's letters are generally written like print, ladies' like copper plate, and gardeners' ditto, showing clear intellectual perceptions however hard and horny the fingers that held the pen; and, in the clearness of the arrangement, showing what advances have taken place since Mr. Loudon started the "Gardener's Magazine," as we had it from his own lips that for several of the first volumes every article sent had to be rewritten, except those from one correspondent (Mr. Gorrie). Would that that philanthropist could now see the results of his labours. And, then, thirdly, though Mr. Robin did outlive, by some means, our *sulphur fumigation*, we never found anything else that did. Flies, newts, toads, and frogs, if we did not see or remove them, or if not covered over with earth, generally lost their lives. And what we wish especially to press on every reader is the necessity of making sure that the wood of deciduous trees is thoroughly hard and ripened before burning sulphur in the house in which they grow. There is no plan better for settling the scale, &c., than such a smoking; but every green bit of wood will be sure to suffer. We have done Peach trees in a similar way, but the ripeness and hardness of the wood are essential considerations, and the house ought to be opened next morning; and, if the weather should be sunny for a day or two, the house should also be shaded until all smell of sulphur has gone. We have lately had several inquiries on the subject; and what we want to impress is, that when the wood is hard and thoroughly ripened, burning sulphur is a good servant. In every other case it is a devastating master. Unless the conditions are sure, be content with washing and other means instead of so using sulphur. It is also best to burn sulphur in a house when the woodwork and the house, as a whole, are dry. When wet, there is apt to be such a chemical combination as would affect the colour of the paint. Once we burned a quantity of Laurel leaves with the sulphur, and the rafters became of a shining dark blue, from the formation of a prussiate of lead. We tried to wash it off and failed, but in about a fortnight the atmosphere changed them gradually to their natural colour.

KITCHEN AND FRUIT GARDEN.

Much the same as last week. When Vines in pots are rising two years old—that is, had two summers' growth, they may be started in any house with an average temperature of 50°, and so may Peaches, Apricots, and Cherries, though 45° will be sufficient for the three last at first, and the two last should never have above 55° at night until the fruit is set, and plenty of air given when in bloom, and even a little shading if the weather should be very bright. For younger Vine plants—say struck from eyes last January, and intended to fruit about the end of May and the first part of June, a bottom heat of 75° will be of great advantage to them, increasing it to 80° and 85° as the Vines get into bloom. For all early forcing in pots, bottom heat will be an advantage, provided mere growth is not encouraged instead of the fruiting part. Thus Peaches and Apricots out of doors often go blind because there is no reciprocal action between roots and tops, because the wall is sooner heated than the roots at the bottom of the wall, and hence the importance of any screen that will keep the blossoms back until warmth also brings the roots into action. When trees are in pots we can prevent all this by giving the roots a push on, rather in advance of the buds, so that when they expand and open there shall be plenty of sap ready to sustain them. This bottom heat must not be carried too far, or the roots will lose their vigour and robustness, and also be apt to be burned. For Peaches about 60°, Apricots a little less, and 55° for Cherries, would be about high enough until the fruit was set. Another thing, as alluded to above—too much bottom heat will so encourage leaf growth, as to discourage fruit-buds so much as to cause them to be thrown off, or shrivelled up. For instance, in the case of Strawberries. I speak not of April or May, but of the beginning of January. Plugging the pots in a mild hot-bed of leaves is very apt to cause the roots to come through the pots into the leaves, and the lower leaves are thus so much encouraged, that the central fruit-bud may be starved or shrivelled. When early Strawberries are thus plugged the heat should be moderate—little above 60°; plenty of air given, and the pots should stand on a hard substance, such as tiles or boards, that the roots may be induced to ramify in the pot, instead of coming outside of it.

This latter remark should apply to all fruiting and flowering plants that are to be forwarded with bottom heat, and which

are intended afterwards to stand exposed on a stage or platform. Rightly used, this bottom heat is ever a powerful auxiliary; but, like liquid manure, it should not be abused. This brings us to some queries as to potting now plants of Vines and Peach trees intended to fruit early this season, with or without bottom heat. If the plants are in a good condition for fruiting, we would rather keep them in the pots in which they are, and top-dress with rich compost, and give manure water as needed. If we were obliged to shift by having the plants sent with balls, we would plant the pots in a bed of tree leaves out of doors, covering the pots all over, and making sure that the roots averaged 70° to 75°, whilst the tops were exposed to the atmosphere, with, perhaps, an evergreen branch stuck among them. When the roots were running freely, then place glass over the plants, or remove them under glass, and if still with a little bottom heat all the better. But in the case of well-ripened Vines—say in eight or twelve-inch pots, we would prefer fruiting them in these pots and top-dressing as above; and where showing the fruit in pots was no object afterwards, then we would widen the hole at the bottom of the pots and allow the roots to go out as they liked, either in a bed of soil, or of coal, decomposing, fermenting matter, that gave a little gentle heat at first. The plant would go on without receiving any check until the fruit showed and was set; and then the increased room for the roots would give nourishment to the fruit, provided the foliage was not allowed to take all the running, but stopping and disbudbing were duly attended to.

FORCING FLOWERS.

The importance of a mild heap of tree leaves can hardly be over-rated for the forcing of all hardy shrubs, plants, and bulbs. Everything will bloom all the better if the root action precedes that of the bud action. How nicely the Hyacinth and Narcissus do when this bottom heat is judiciously applied at this season! How well it answers with all deciduous shrubs, as Lilacs, Thorns, Rhododendrons, Azaleas, Deutzias, &c.; and the same may be said of many herbaceous plants, as Musk, Fumarias, Lily of the Valley, &c. Of course, they will come in any house where heat is applied, but always better when bottom heat can be judiciously given: hence every tree leaf is of importance for getting artificial heat now, and a stock of compost afterwards.

PROPAGATION.

In autumn many things do best when struck cold, though they take longer time, and in the spring of the year the whole of the plants intended for grouping in the flower garden, and which do well from spring cuttings, will answer best when placed in a heat averaging from 55° to 65°, and considerably higher at bottom than at top. Verbenas in such cases will strike like couch grass—so much so, that we frequently make a bed on purpose, and stick it full of cuttings about 1½ inch apart, so as to dispense with pots and their substitutes, taking the frame off as soon as they have struck, and protecting with boughs, &c., until planting time. Even such hardy things as Chrysanthemums when struck in spring are all the better for a little bottom heat, and to be plunged in a mild heat after getting their first potting, and hastening them gradually to the open air. In fact, the right use of bottom heat at this season from simple means is a matter of no little importance.—R. F.

TRADE LISTS RECEIVED.

Descriptive Catalogue of Annual, Biennial, and Perennial Flower Seeds. W. Thompson, Tavern Street, Ipswich.—This is a very copious and excellent selection. The plants are not only arranged according to the natural system, but there is an alphabetical index, and each species is briefly described, so that it is really a very useful catalogue for either the amateur or gardener to keep for reference.

TO CORRESPONDENTS.

*** We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the "Journal of Horticulture, &c.,"* 162, Fleet Street, London, E.C.

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

We cannot reply privately to any communication unless under very special circumstances.

HEATING CONSERVATORY. *Jan.*—From the ground plan shown, the pipes might so under the shell all round, and if 9 inches from the sides of the conservatory, they would harm them but little. A lower plan might be to have the front border edged with ornamental ironwork, stout enough to conceal the pipes, or to form the pipes the sashes. The edging to the central bed might also be so done. If these should be objectionable, we would rather have the pipes in the side path-way, and either have iron gratings with stone sides, or stone flooring, and brass grates in the stone. The iron grating would be best. In such a beautiful house we would confine pots to the sides, and have a bed in the centre. The appearance could be changed by plunging pots in the bed. A stage in the centre, and a covering over the pipes, would be roughly disapproved; it would be a mingling of what should be distinct. If stage at all, have it all stage. The bed, in the circumstances, would be the handsomest. Close to the pathway it might be planted with Swiss moss; and green moss might be used in the centre, covering the plunging in, so that only a few fine, tall plants need be planted out permanently.

DETECTING ONCHIDS. *(A. B. C.)*—It will be more prudent not to order the hardy Onchids from the nurserymen till about the first week in April. They will then be rooted and pushing their buds. If you desire to have a considerable number of species, you would be more certain to get them by advertising for them. Many nurserymen do not advertise at all, and those who do, do not always particularise their whole stock.

DUB. *(A. St. Alban's Subscriber.)*—Your drawing of the bulb is sufficient. From it and the leaf you sent we should say it is some Nerine, that is going to bloom too late, or some bulb very near to Nerine; but there are five hundred kinds of bulbs which will grow, at some stage or another, just like your drawing and like the leaf you sent; so no one could be certain of the name from the look and leaf. When it blooms, if it is a Nerine, all the swards unite at the bottom in a swelling, or "gibbous union," which is the family crest. If the stamens do not thus unite it is not a Nerine, and you must send us a bloom or two with the full length of the peduncle, or flower-stalk, in a tin case, or in square wax to prevent it being flattened or put out of shape. At the same time say where the bulb has been kept for the last two years, when it went to rest, or if it did rest how long it remained dormant, and at what stage in the growth of the leaf the bulb usually blooms.

SMALL CHARCOAL. *(F. J. L.)*—We have not "J. B.'s" present address; but you may obtain it from a small charcoal at any large charcoal dealers most easily. As it had been so at the place we know far distant from London. We should prefer fuel in a small greenhouse, the small coke and breeze which you may buy at the gasworks for a trifle.

VINES GRAPPLERS IN ICE. *(A. B. C.)*—As your Vines are so high and strong, through ripening of the wood stems, and the more prostrates than many others, a dressing of horse dung on the border, or superphosphate of lime will be good—say a quart of a hundredweight of superphosphate to 500 square feet. From your description of the Vines, however, we should not be surprised if the roots need raising. It may be, however, that the unusual summer of 1860 was the cause of the unfruitfulness, by not ripening the young wood.

HEATING A COLD PIT. *(An Old Subscriber.)*—So far as we can see there is no difficulty at all in the matter. The space between the pits is of no consequence whatever. If you place the pipes in a hollow arch, and open at the end into the cold pit, the most of the heat will thus enter it; and if at the end next the propagating pit there were an opening to shut or open at pleasure, you might thus have a constant succession of fresh air, somewhat heated, pouring into the pit. As being more effectual, and also more out of the way, we should prefer the pipes to be placed next the front of the cold pit. The heating will be quite sufficient to keep out all frost, &c., but not to force things very early. We presume to it the mode of connection with the pipes in the propagating-house, or with the boiler, is understood, as there are no questions on that subject. The tilting the sashes will do well enough, and it would advise* by a pit to break the wall for ventilation in it most of the year, and to be shut in the winter when building. There would have been less necessity for moving the sashes. Even now a few slides inserted in the front wall, 12 inches long, by 3 inches or 4 inches wide, just over the pipes, might be an advantage.

FORCING LABURNUMS.—E. M. will be obliged by "O. B." stating at what age, and how he propagates Laburnums for forcing.

PAST-CASE FOR EXPORTING PLANTS. *(An Old Subscriber.)*—Make it of wood, one inch thick, with level-related corners; the top 1½ in. d., and one side only glazed, with strong wire net over the glass. It need not be absolutely air-tight; but the glazed side must fit close enough to exclude sea water.

BLACK MUSCAT OF ALEXANDRIA. *(A Subscriber.)*—This Grape was in the collection at Chiswick Gardens about five years ago. It is not there now. We are told that it was well known about Paris. Whoever gave it a bad character was entirely wrong. It is a very fine white, or citronia, is a stove evergreen shrub, native of Jamaica, with yellow, sweet-scented flowers. You will find an account of it in Don's "General History of Plants," &c. 88. We do not know the walk you mention. It is certainly no authority.

NAMES OF FRUIT. *(J. H. G. Garswood.)*—The Apple you have sent is the Count of Wick, so your third net was quite right. (P. L. Y.)—Your Pear is certainly not Knight's Marchion. The true one is a round Pear, and one of the best in cultivation. That which you are now growing for it is quite another.

—No. 1 is Pearson's Plate, a capital dessert Apple; 2, Caville Blonde; 3, Count of Wick; 4, Duval's Seedling.

NAME OF PLANTS. *(J. B.)*—Yours is a very small fragment, but it looks like *Deeringia Amherstiana variegata*, an East Indian shrub, cultivable in a

warm greenhouse. *Spiraea Lindleyana* is a pinnaet-leaved deciduous species. There are: no evergreen shrubby *Spiræas* (*H. H. Mayer*).—1, *Aspidium fragrans*; 2, *Adiantum tenellum*, a small var. of *hispidulum*. We have had no experience with the Holly fern planted in the greenhouse this winter. Being rather a difficult species to cultivate, we should advise your trying it, and reporting the result. Pot firmly. (*Cleome Rosey*).—4, 1 and 5, *Abies Menziesii*; 2, *Pinus excelsa*; 3, *Pinus cephalonica*; 4, *Pinus pinaster*, robust; and 7, the same, less robust; 6, *Juniperus chinensis*; 3, *Pinus pumilio*; 3, *Abies concolor*.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

CHRISTMAS POULTRY MARKET.

It is said one half of the world knows not how the other lives; and it is certain that the other half has not the slightest idea by what means, and in what manner, those things that are immediately necessary to their comfort and well-doing are brought to their doors and into their dwellings. The children's books of the present day are far more replete with information and sound knowledge than were those their parents read when they were nearly grown up, thirty years ago; and Peter Parley has done much for the rising generation. Again, good illustrations have done more; a correct and plain picture will teach more, and, above all, give a more correct idea than sheets of letterpress. But there are some things that cannot be drawn and engraved. Among them is Leadenhall Market at Christmas time. We will endeavour to describe it. No one can form an idea of the enormous quantity of food consumed, or rather sold, during eight or nine days before Christmas-day. Most people make and receive presents during that time; and we believe it is a fact, that a man at the head of a very large retail business in the City marked a hare and gave it away. From wholesale men and others it came back to him (the identical hare) three times during the week. Whether as an expression of obligation for favours during the year, or from a good and laudable observance of an old custom that urged those who had it in their power to distribute good cheer among their connections and dependants, we cannot say; but it is certain enormous purchases are made by the large City houses for distribution among their customers. Distillers and brewers send to publicans; woollen-drapers to tailors; millers to bakers; timber merchants to builders; builders to architects, and so on. A large firm will spend in Turkeys only from £200 to £300, and many add thereto a hamper of Game and a Stilton cheese. Then, among the large buyers of poultry in the shape of Geese, come the holders of goose-clubs. These are well-to-do publicans. About August placards in the windows state the goose-club has begun. Every man who pays in a small weekly sum has his goose and a bottle of spirits at Christmas.

There is generally a lull before the busy week sets in. Every one in a shop or at a stall, from the master downwards is aware that a heavy time is coming. All the odd corners are cleared out, everything is removed from the premises, and the experience of years is brought into play to multiply accommodation and to increase facilities. Those who, wishing to see the course of the Christmas market, went to Leadenhall one day too soon—that is, before the goods came in, would be surprised to find "empty benches," and men who were husbanding their resources by hardly giving an answer to those who put a question to them. In a description we have read of a fishery in Italy, it is said that news having been brought that the fish are off the coast, all the fishermen drew up their light boats, and form in listless groups on the quays. At last, as far as the eye can see, there is a ripple that slowly but gradually increases. All strain their eyes, but none will give the first warning, because of the laughter that follows a mistake. Several have the same impression; and at last, doubt ceasing, all cry out "The Fish!" and every man to his boat, whence in a quarter of an hour he is killing as best he can.

Just so, the shops all swept and emptied; the master sitting, it may be on a chair or on a hamper, and the men standing about. Buyers are careless, seeing they have a week before them. Jokes are passing. Salesmen say, "Things will be very short;" buyers say, "The weather is very bad." Salesmen say, "Things are bought very dear in the country;" buyers say, "There is no one to give a price in town," and badinage goes on till a truck appears at the top of one of the passages leading into the market.

It is very well to talk about the men of olden time, and the burdens they could bear. "Nonsense all, my merry masters."

People used to talk about the giants of the days of chivalry, when men went in plate and chain armour, "cap à pic." When some of the noblest and oldest of the land furnished the armour of their ancestors for the Eglington tournament it was a world too small; and when the Lord Mayor treats the cockies to a "knight in complete brass armour," "ditto in steel," "ditto in chain," "ditto in a Milan suit." He once wrote to the Colonel of the Life Guards, asking the loan of the four tallest men in his regiment to be knights in armour for the day. On comparing the men and their "stubborn suits," it was found they were too tall, too stout, and too wide; and the first magistrate of the city sent for the four smallest of the Light Dragoons kept at a long low building near the Kensington Gate, for escort purposes.

Put two of your men "of the olden time" to that hand-truck, and see if they will run up the hill with it. A long, narrow truck, with two handles, running on two massive iron wheels about 5 inches in diameter, shod with an iron semicircle at bottom, which turns up, and thereby prevents the load from slipping off, bearing now four huge hampers. Only those who have packed and carried poultry know how closely it lies, or how heavy it is. The sight of the men leaning to their burden is as the fish to the boatmen. Every man looks up. "Eastern Counties!" says he who has pushed behind; while the front man (albeit the streets are frozen, and perhaps the temporary spots at the plugs are besieged by shivering boys and maid servants fetching water) takes off his hat or cap, wipes the water from his smoking brow, and eases his panting chest. "Many?" asks the salesmen. "Don't know; we have about a hundred tons below in the street." These, the Eastern Counties, bring the best and largest Turkeys, huge Geese, and average fowls. But this truck is like the broomstick that was sent for the beer—it never stops. It is always running up and down, fetching its load. It is not alone. The stream has set in; the Great Northern, the North-Western, the Great Western, all pour in supplies. One brought this year 900 tons one morning. Now the market loses all shape and form. There is barely room to pass between the piles of hampers that threaten to fall down. Talk of beetling cliffs, we are not sure the overhanging hampers would not be quite as fatal. Few people have any idea of the weight of three score of fat Geese. The work of the market begins. The huge flats and hampers discharge their contents. The shops so empty yesterday are now full of Geese, Turkeys, and fowls. The Turkeys hang in double and treble rows; and some idea may be formed of the value of the stock as it arrives when we say the row that is just put up in that shop will make £60. The old tradition of Turkeys is 1s. per lb.; but that holds good only to a certain weight. Taken as an average it may be called the present value.

What will be said of a salesman taking in a day £1000 in small sales of casual passers-by? It is perfectly true. Imagine the Christmas market has lasted two days; spite of wholesale and retail buyers the quantity of goods increases. Not only is the market piled up till circulation becomes almost an impossibility, but the hide market adjoining Leadenhall is also full of waggon; it has become impossible to unload, and, therefore, the horses are taken out and the goods are watched. The shops at market will not shut up any more till Christmas is over. The retail poultryers have covered their fronts with cloths. Policemen patrol and divide the watch with sleepy men. Here and there snoring will tell you that some are snatching a few hours sleep; and, if you look, you will see them curled up in some straw. It will be but a short nap. The public was in possession of the market at twelve o'clock—it took an hour to put away; and, before five, the waggon will be unloading. About six the retail poultryers begin to arrive from all parts, buying is a real business with all these men, and, for an hour there seems a hope that the stock will decrease. It is only a hope. The everlasting trucks are at work again, and the man in the shafts, as he is jocosely called, is suddenly brought up in his effort to drag three hampers, 5 feet wide, through a space of 3½ feet: this causes a stoppage, and then it takes half an hour's patience on the part of the police to restore things to a proper flow. This suffices to show the amount of goods pouring into the small area covered by the market; stop it for a few minutes and you will be astonished at the mass it forms.

Now, then, having viewed the market, and seeing it lighted with gas *a giorno*, loaded with goods that it would seem hopeless to expect can be eaten while avert, let us view some of the principal actors in the scene. Just imagine the mind of a large salesman

during the week. He has two or more thousands of pounds worth of goods before him, all belonging to different people, and which it made up of small sendings. Do any of our readers recollect the new Foreign Secretary of the Republic in "Jerome Putrot?" Installed in his new office, he is at once told there is a misunderstanding at Tiflis, a coolness with Trabzon, and an affair at Teheran. No marvel if he mixes one with the other. So the salesman has twenty-one cock Turkeys from T. S. Fakenham, seven y hens from F. T. Fakenham, thirteen hens from G. L. F. and a hundred from F. I. G. The same in Geese.

TRIMMING SPANISH FOWLS.

I was much gratified at seeing in your "Letter Box" of last Tuesday, a strong condemnation of the practice of trimming Spanish fowls over the eye, &c., and an exposure of the disgrace that would be expected from the Judges on any detected culprit.

There is a prevailing opinion existing amongst amateurs, and confirmed by your own remarks upon the shows, that the trimming of Spanish fowls is becoming general—encouraged, probably, by the non-infliction of the threatened judgment. As this may arise from the difficulty of deciding whether a bird is trimmed or not, perhaps the suggestion of a magnifying-glass may not be unimportant.

If the requisite points may, without penalty, be produced artificially, one great stimulus is removed for breeding them naturally; and the result would be ignominious to the laudable and interesting amusement of "the poultry fancy," and must also prove detrimental to poultry sales. For who would give £10 for a bird if he expected that after the first moulting it would be only worth 2s. 6d.?—AMATEUR.

PHILOPATERON SOCIETY'S ANNUAL SHOW.

ON Friday last the annual Show of the birds belonging to the members of this Society was held at the Freemason's Hall, Great Queen Street. It may, perhaps, be desirable to inform some of our country readers that this Exhibition differs entirely from an ordinary show, inasmuch as there is no competition for prizes, and the birds are exclusively the property of the members, who incur the great trouble and expense of engaging the Hall yearly for the pleasure of inviting their friends to see their truly magnificent collection of birds. The Hall was filled with the highly ornamental pens belonging to the Society, and there were many hundred birds exhibited.

The *Fowlers* occupied the most prominent position at the end of the Hall. Mr. Eden, of Salford, exhibited some magnificent Blues, and one of the grandest pair of Black-pied birds that we have ever seen. Mr. Butts' birds were, as usual, the object of great attraction; his Blues and Whites being particularly elegant. Some of Mr. Haynes' Pouters were particularly good. We noticed especially a pair of Mealy, and some Yellows that for size and soundness of colour were highly commendable. Mr. Tegetmeier also exhibited some exceedingly good Whites of great elegance of shape.

The *Carriers* were extremely good. The style of Mr. Haynes' birds is too well known to need description. Mr. J. also exhibited a pen of very first-rate birds, rather heavier in style than Mr. Haynes', but of undeniable excellence. Mr. Chalker, of Plymouth, and Mr. Parkinson also forwarded good specimens.

Amongst *Sheriffed Tumblers* Mr. Lucy's Almonds were pre-eminently beautiful for their extreme goodness of colour and markings. Mr. Esquilant's were much noticed for their exquisite form; and his Mottles and Tumblers generally fully maintained his reputation as a most skillful breeder. The Blue and Red Beards and Almonds of Mr. Archer were fully up to his usual standard of excellence. One of the greatest features of the Show was the extraordinarily good character of the *Parls*, of which two large pens were shown by Mr. Stevens, of Axminster and Mr. Eden. One of the Yellow cocks of Mr. Stevens appeared to us as the best bird of that colour that we have ever seen. The *Turbits* of Mr. Stevens were very good, not only in colour but also in form. Mr. Wicking, who, after a short absence from the fancy, has returned to a pursuit in which he was so successful for so many years, exhibited three pens of German birds, two of *Stallers*, and one of very excellent White-berred *Bird Priests*. A large pen of *Archangels* was shown by

Mr. Stevens, but they were not in quite as good feather as his other birds. Mr. Harrison Weir's pen of *Fantails* fully maintained his ancient reputation as having some of the very best birds of that variety. The only important varieties not exhibited were *Ossls*, *Trumpeters*, and *Runts*.

The Exhibition was delivered by a very good performance of music by Messrs. Shapcott. The attendance of visitors was almost inconceivably great, and the Show may be said to have passed off with great success. The absence of the mingled feelings that necessarily result from a competition for prizes, the extraordinary merits of the birds exhibited, the character of the visitors, and the general completeness of the arrangements, render the Philo Show the most agreeable runnings of the kind in the kingdom. We therefore hope that the prosperity of the members may continue to increase.

And when they next do have a show,
May we be there to see.

ABERDEENSHIRE POULTRY SHOW.

This First Show of the Society was held in the Music Hall, Aberdeen, on the 1st and 2nd inst. We are informed that it was a very satisfactory gathering, and that it would have been still more so if it had not been held at the same time as the Perth Exhibition. The following is a list of the awards:—

POULTRY.

SPANISH.—First, B. Samerville, Cattle Market, Edinburgh. Second, G. Taylor, Inverury. Third, W. Hay, Aberdeen. *Chickens*.—First, W. Hay, Aberdeen. Second, J. Reid, Fetterleicher, Fyvie. Third, B. L. Reid, Balauch, by Oldmeldrum.

DORKING.—First, Madame Thomond, Park House. Second, Mrs. J. Wagstaff, Westerton, Huntly. Third, Dr. Wilson, Oldmeldrum. *Chickens*.—First and Third, Madame Thomond, Park House. Second, G. Taylor, Inverury. Highly Commended, J. Anderson, Ruthven House, Meikle. Commended, Mrs. J. Wagstaff, Westerton, Huntly; Mrs. Ironside, Brae Cottage, Keithhall.

CORNHEN.—First, G. Murray, Aberdeen (and very highly commended for cup). Second and Third, Madame Thomond, Park House. *Chickens*.—First, J. Reid, Fetterleicher, Fyvie. Second, Madame Thomond, Park House. Third, Mrs. W. Papper, Belhelvie Village.

GAME.—First, H. E. Brown, New Stone, Perth (also winner of silver cup). Second, S. Pope, Aberdeen. Third, T. Douglas, Aberdeen. HAMBURG Silver of gold-pencilled.—First, Mrs. White, Athol Place, Perth. Second, G. Taylor, Inverury. Third, J. Gordon, Manar. Commended, A. Hay, Aberdeen.

H. Hatched Silver of gold-pencilled.—First, G. Taylor, Inverury. Second, W. Hay, Aberdeen. Third, Mrs. G. Davidson, Aberdeen. Commended, G. Taylor, Inverury.

POULTRY (any variety).—First, S. Pope, sen., Aberdeen. Second, W. Hay, Aberdeen. Third, S. Pope, Jun., Aberdeen.

BASTARDS any variety.—First, J. Edwards, Aberdeen. Second and Third, J. Anderson, Ruthven House, Meikle. Commended, Madame Thomond, Park House.

REDDISH POULTRY.—First, Second, and Third, Madame Thomond, Park House.

ANY OTHER VARIETY.—Highly Commended, Madame Thomond, Park House.

GEES (any colour).—First, J. Alexander, Firdon, Hillside. Second, J. Gordon, Manar. Third, G. Tomp, Jun. Field, Cults.

EGGS.—Aylesbury.—First, Mrs. J. Wagstaff, Westerton, Huntly. Second, G. Davidson, Belhelvie Village. Third, Sir J. D. Elphinstone, Bart., M.P., Logic-Elphinstone. Commended, G. Tomp, Janefield, Cults.

Ducks (any variety).—First and Third, W. Forbes, Whiteford, Pitcairney, Cumbrodale, W. Strath, Aberdeen. Second, J. Mitchell, Aberdeen.

TURKEYS any colour.—First, Mrs. B. Wilson, Hayfield, Hilton. Second, A. F. Williamson, Caskin Mains, Blackburn. Third, Sir J. D. Elphinstone, Bart., M.P., Logic-Elphinstone.

DIGGONS.

TURKEYS.—Highly Commended, W. Wilson, Aberdeen. Commended, J. Hay, Aberdeen.

FANTAILS.—Highly Commended, G. Clammers, Aberdeen.

POULTRY.—First, J. Hay, Aberdeen. Second, F. M. Rae, Aberdeen.

RULES.—Highly Commended, J. Hay, Aberdeen. Commended, J. Hay.

CANARIES.

YELLOW PIGEON.—Cock.—First, K. Campbell, Aberdeen (and winner of entrance of the Test bird in the Show). Second, J. Hunter, Aberdeen. Third, A. M. Blair, Aberdeen. Highly Commended, W. Jamieson, Aberdeen. Commended, W. Strath, Aberdeen. Fourth, J. Mitchell, Aberdeen. Second, W. Wilson, Aberdeen. Third, W. J. Rontledge, Aberdeen.

BLUE PIGEON.—Cock.—First and Bird, W. Ogilvie, Aberdeen. Second, W. Murray, Aberdeen. Commended, W. Wilson, Aberdeen; J. Mitchell, Aberdeen. Bird.—First, W. Jamieson, Aberdeen. Second, A. M. Blair, Aberdeen. Third, K. Campbell, Aberdeen. Highly Commended, J. Mitchell, Aberdeen. Commended, A. Ferguson, Woodslee.

TRICKED.—Cock.—First, J. Macdonald, Aberdeen. Second, A. Wilson, Aberdeen. Third, J. Mitchell, Aberdeen. Highly Commended, K. Campbell, Aberdeen. Bird.—First, J. Macdonald, Aberdeen. Second, K. Campbell, Aberdeen. Third, W. J. Rontledge, Aberdeen.

COMMON CANARY.—Cock.—First and Second, Mrs. E. Evans, Broadford Cottage, Aberdeen. Bird.—Highly Commended, S. J. Mitchell, Aberdeen.

MULE.—First, S. J. Mitchell, Aberdeen. Second, W. Gordon, Aberdeen. Third, J. J. Gordon, Aberdeen.

PRIZES GIVEN BY A MEMBER OF THE ASSOCIATION.

SPANISH COCK.—Tritie, B. Samerville, Cattle Market, Edinburgh. Highly

Commended, Mrs. White, Athol Place, Perth. Commended, W. Hay, Aberdeen.

DORKING COCK.—Prize, R. Walker, Hillside House, Portlinton. Commended Mrs. Ironside, Brae Cottage, Kithlithal.
COCHINS—CHINA COCK.—Highly Commended, J. Reid, Fetterfield, Fyvie.
GAZE COCK.—Prize, W. Hay, Aberdeen. Highly Commended, T. Douglas, Douglas Hotel, Aberdeen. Commended, Mrs. Bennet, Alerde n.
 Silver Cup to the Owner of the best Pen of Fowls in the Exhibition.—H. E. Brown, New Scene, Perth, for Game Cock and pair of Hens.

JUDGES.—Of Poultry, Mr. John Kidpath, Edinburgh; Mr. W. W. Johnston, Broughly Ferry; Mr. Robt. Copland, Silvermoss. **Pigeons and Canaries.**—Mr. M. Clelland, Perth; Mr. Mitchell, Perth; and Mr. Darnit, Aberdeen.

PLYMOUTH AND WESTERN COUNTIES POULTRY EXHIBITION.

THROUGH the indefatigable exertions of an untiring and persevering Hon. Secretary, the Plymouth Poultry Exhibition has, we believe, become an established fact; and whilst congratulating Mr. Sandford and the Committee on the success which they achieved at this their second Exhibition, we also rejoice at being able to congratulate our readers on the probability of an annual treat such as we enjoyed on Wednesday and Thursday last—for treat it was, if only to take a walk round the different classes for Game fowls collected together in the splendid Assembly Room adjoining the Royal Hotel, on entering which we could but be struck with the excellent arrangements for the comfort and safety of the 300 pens of valuable poultry collected there. As a proof of the excellence of the arrangements, all the Game fowls were on a level, taking the whole of the top rows; therefore they showed to a great and equal advantage, whilst those birds beneath them were sufficiently high to admit of their being seen with but little difficulty.

But to review the different classes, commencing with Black-breasted Red Game, in which Mr. Swift obtained first with a noble pair, well deserving the honour they gained; hard run, however, by Mr. Mathews, whilst many of the highly commended pens were but a short way behind. But the gem of the Game fowls, however, was to be found in the first-prize pen of Brown Reds containing such a cock as we seldom, if ever, saw—in the very best of condition, perfect in feather, and hard as a board, with a hen well worthy of him. To this deserving pair we need scarcely say the cup was awarded as the best pair of Game fowls in the Exhibition. We believe Mr. Sandford, the fortunate owner of this much-to-be-coveted bird, refused £10 offered for him by Mr. Archer, of Malvern, or his representative. Mr. Burgess also exhibited an excellent pen. In Duckwings, the winners of the first prize travelled all the way from Beverley, but still were shown to great advantage. We need scarcely say they were Mr. Adams'. Mr. Dawson was a good second in the "any other variety" class. The first prize went to a good pen of Blacks; the second to Whites.

In Spanish, Mr. Rodbard had to succumb to an excellent pen of Mr. Lane's, which, if we mistake not, were the Birmingham winners. We thought the former gentlemen were not in the condition he readily exhibits them in. Mr. Heath's well deserve the prize they won.

Dorkings afforded another and a greater triumph to Lady Louisa Thorne, who obtained both first and second prizes with magnificent birds; whilst a good pen of Rose-combed exhibited by Lady Julia Cornwallis, had to be content with a third. But amongst the commended pens were to be found many worthy of prizes.

In Buff Cochins Mr. Tomlins's were not up to his usual standard; he, therefore, had to yield the laurels to a superior pen of Mrs. Fookes'; whereas in the class for any variety Mr. Ford had it all his own way, taking both first and second.

The **Hamburghs**, were weak in numbers, and, if we except Lady Julia Cornwallis's Silver-spangled and Mr. Martin's Silver-pencilled, poor in quality; Lady Cornwallis taking both prizes for her class, and the cup for the best pen of Hamburghs in the Exhibition.

Pollards were represented by one pen of Silver only.

In the "Variety class" the first and third went to Brahmas; whilst the second and fourth went to Indian Game and Crevé Cours respectively.

Game Bantams were in great force, mustering thirty pens, being nineteen of Reds, and eleven of other varieties. Mr. Cumm and Mr. Bayly taking the prizes for the former; and, in the latter, Mr. Rodbard obtained first with a pretty pen of Piles,

which were immediately claimed at the price they were entered at—£5 10s., and, doubtless, the fortunate purchaser was much pleased with his bargain. Mr. Cumm's Duckwings also well deserved their honours. In Sebrights Mr. Lewis's Golden and Silver were perfect, and with them he obtained both first and second prizes, Gold taking the precedence. Mr. Horton's pen of Blacks was first in the variety class, and hard run Mr. Rodbard's Pile Game for the medal; but it was eventually awarded to the latter pen.

As usual Mr. Fowler reigned supreme in **Ducks**, taking both first and second for Aylesburys, and first for Rouens, with splendid birds; his second-prize pen of Aylesburys being immediately claimed at four guineas. In the class for Ducks of any other variety Mr. Sandford obtained first with a capital pen of East Indian, Mr. Bayly's well-known pen of Brown Culls being second; whilst Mr. Martin's was third.

In **Dorking cocks**, Lady Julia Cornwallis's well deserved the prize she won.

Game Bantam cocks mustered sixteen pens of as good birds as often compete together. The cup and sweepstakes were, however, awarded to a beautiful little Grey, the property of Mr. Forest, and we shall be mistaken if he does not yet add to the stock of plate with which he has already helped to deck his master's sideboard.

The **Game Cocks** were a show in themselves: twenty-two of the best birds England can produce entering into a spirited competition for a handsome seven-guinea cup, in addition to a sweepstake of 10s. 6d. each. It, however, went, and we think most deservedly, to one of the best Black Reds we ever saw, the property of Mr. Archer, and it would be difficult to find a better model of what a Black Red Game cock ought to be; and, as he walked round his roomy pen, we could not help remarking that he looked like one of the right sort—one that would fight amain with credit to his owner and himself; as, after all, that ought to be the standard, as, if cock-fighting is not now indulged in (and it is not at all desirable that it should be, nevertheless), a Game cock that could not or would not fight is not a Game cock at all: this is a fact which some of the Game breeders of the present day seem quite to have lost sight of, and let their feelings of humanity carry them a little too far. Mr. Burgess's second-prize bird is, however, not to be classed among these, as he was evidently both ready and willing to do better with anything or any one who may give him cause. There were too many other birds in this class well worthy of mention for us to have time or space to enumerate them; but out of the whole twenty-two pens, there was not to be found a bad bird amongst them, and that is saying a great deal.

The show of **Pigeons** was limited to Carriers only; therefore it was not large, but unexceptionably good; Mr. Square and Mr. Goss taking the principal prizes. Mr. Holman also showed excellent birds.

The weather was fine and the attendance good, everything going off to the satisfaction of all parties; and we do say Mr. Sandford is well deserving of the most hearty thanks of the whole poultry community for bringing about such a result—for through him was the Show established; through his exertions has it been brought to the position which it now holds in the poultry world; and through him was it that exhibitors had such a treat afforded them last week as they seldom have in the West of England; the entire management doing the worthy Hon. Secretary the greatest possible credit, as there were no delay, no confusion, no mistakes, and, therefore, no complaints.

Long may Mr. Sandford live, and may Plymouth Poultry Exhibition go on year by year steadily improving, must be the hearty wish of every poultry exhibitor in the United Kingdom.

GAME (Black Reds).—First, R. Swift, Southwell, Notts. Second, S. Mathews, Chilton Hall, Stowmarket. Highly Commended, Rev. G. S. Cruwys, Cruwys Morchard, Devon; S. Dupe, Evercech, Bath; E. Archer, Malvern; V. Sandford, Chatsworth Lodge, Mansfield; J. Rodbard, Aldwick Court, Wiltshire. (An extraordinary good class.)
GAME (Brown Reds).—First and Cup, V. Sandford, Chatsworth Lodge, Mansfield. Second, J. Burgess, Burleydam, Whitechuck. Highly Commended, T. Shaw, Kirkham, Lancashire; J. Brackelidge, Chew Magna, Bristol; W. Dawson, Selly Oak, Birmingham. (An extraordinary good class.)

GAME (Duckwings and other Greys and Blues).—First, H. Adams, Beverley, Yorkshire. Second, W. Dawson, Selly Oak, Birmingham. Highly Commended, S. Mathews, Chilton Hall, Stowmarket; R. Swift, Southwell, Notts. Commended, A. M. Sloper, Seend Park, Melksham; S. Dupe, Evercech, Bath.

GAME (any other variety).—First, J. Weeks, Bromyard, Worcester. Second, J. Camp, Farnside, Southwell. Highly Commended, W. Dawson, Selly Oak, Birmingham; Rev. G. S. Cruwys, Cruwys Morchard, Tiverton. Commended, V. Sandford, Chatsworth Lodge, Mansfield.
SEABRIST.—First, H. Lane, Milk Street, Bristol. Second, J. Rodbard, Ald-

was liberally supplied. Early in the spring this hive, also in my town garden, showed great activity and forwardness, and was removed into the country about the end of March. On inspection the combs filled but about two-thirds only of the interior—a positive refutation of the idea expressed by your Oxfordshire correspondent at page 283, that such hives are not worth keeping through the winter. This was by far the best working hive I had. On the 17th of May I drove out every bee, obtaining a magnificent swarm, with which my second Langstroth frame-box was colonised. The parent stock was at this time densely filled with combs and brood down to the floor-board. Cutting these combs out of the skep, I fitted them as well as I was able into another set of frames, retaining them temporarily in place with soft lead wire used by gardeners. Adjusting these in my third Langstroth-hive, I looked about for bees to unite to it to hatch out the brood and form a good colony. I fixed on No. 10—a very weak lot possessing a fine queen, a small patch of brood, and a more handful of bees. So wretched had been the appearance of this hive, that only a few days before I had cut out the combs believing there was no queen, but unexpectedly found a very fine one, with a small piece of brood-comb. This, with a few of the other combs, I placed in a small box, intending by degrees to build up, as it were, a serviceable stock, or have a queen ready for any emergency at the time of making artificial swarms. Here, then, was just what was required: the combs of No. 10, fixed in frames, added to those of the driven stock (No. 6), made up the whole number (ten), required. The following day I transposed this artificial stock with a pretty strong one, which supplied the amount of population requisite for rearing the brood. Both the hives, that peopled with the driven swarm and the one with the transferred combs, thrived admirably and rank among my finest stocks.

No. 7, "the adjuster-hive," early in the year promised well. The bees did not take to the super so early as I expected. After partially filling it, they threw off two large swarms. The second issue being almost as large as the first. The super, though containing a good deal of honey, was also made the receptacle for a large quantity of brood. After the issue of the second swarm all the queens must have been lost or destroyed, as the bees fell off in numbers; and while looking about for a spare queen to give them, they were overpowered by a vigorous onslaught of wasps. This hive was at a considerable distance from town, or it would not thus have perished for want of a timely gift of a royal heil.

No. 8 was an octagon-box like No. 2, and also treated like it or an additional bar. But here the likeness ended. Though early furnished with super accommodation, the bees chose to swarm, and—must I confess it?—the swarm flew off, no one except the fortunate finder being the wiser until afterwards.

No. 9 may be cited as a pretty little case of super-posing, which I see on reference to my journal turned out as follows:—A box which had been worked as a super, containing about 20 lbs. of sealed honey, was placed under No. 9 the previous autumn, in lieu of feeding, of which the hive stood much in need. On the 16th of April, I wished to reduce the doubled hive to one compartment only, but on re-moving the lower box I found a quantity of brood, none being visible, so far as I could determine, in the stock-hive, and, therefore, re-stored it to its original position. On the 23rd I changed the place of the boxes, and put what had been the lower one on the top of the stock. The adult bees and those from the sealed brood as it hatched out gradually went below; but the eggs and the youngest part of the brood remained undeveloped, and by the end of the month the box, once more a super, quite deserted by the bees, was removed. This No. 9 came only under the rank of "moderately good" at the time of the April inspection; but it rapidly improved, and notwithstanding that many bees were taken from it to strengthen a weaker stock, afforded a beautiful super of about 20 lbs. weight. This might have been increased, but from its location at a distance from my house, additional room was not afforded them so soon as it was required.

I must defer the consideration of the remaining hives in my apiary for another Number of the Journal.—S. BRYAN FOX, Exeter.

(To be continued.)

VENTILATING HIVES DURING WINTER.

In reply to the inquiry made by Mr. W. Johnson, in page 308, I beg to disclaim all intention of recommending the system

of non-ventilation during winter, which is as yet only on trial with me, and I am especially careful to recommend nothing to others which I have not fully and fairly tested myself.

Some years ago I was induced to doubt the advisability of ventilating bee-hives during winter, from observing instances in which it had so retarded breeding that the colony remained weak the whole of the ensuing summer. I also considered it a state of things that would be very unlikely to subsist among bees in their natural condition, and these reasons have induced me to try the opposite system.

It is a well-known fact that aqueous vapour is present in the air at all times, but more in proportion as the air is warmer. Now, as the temperature of a healthy hive of bees during winter has been proved by Huber's experiments to average above 80°, which is, of course, very much higher than that of the external atmosphere, a similar effect is produced to that which is often noticed in crowded rooms during cold weather. Not only are large quantities of moisture condensed on the windows, but it is seen also to trickle down the very sides of the apartments. This effect is owing to the warm air being chilled by coming in contact with cold walls, when it at once parts with a considerable portion of the water which it had previously held suspended, and which in the case of wooden bee-hives is deposited on their interior surfaces. The result is, that top, sides, and floor-board become ultimately so saturated with moisture as to be totally unfit for their original purpose, and disease supervenes, which either greatly weakens or entirely destroys the whole population.

This unfortunate state of affairs may doubtless be avoided in a great measure, by having recourse to a system of ventilation which checks the deposition of moisture by lowering the temperature of the interior of the hive. This, however, appears to me only the substitution of a greater evil for a less one, inasmuch as Ligurian bees certainly continue breeding during the coldest weather, which breeding must inevitably be put a stop to if the internal temperature be not kept up to its natural height.

My first idea was to counteract this tendency to accumulate moisture by making boxes of thick wood; and, with this view, have used many an inch and a half in thickness throughout. After a fair trial, these thick boxes have, in their turn, been condemned as having failed to fulfil their object. When once fairly saturated with moisture I have found it very difficult to dry them, whilst their weight is so great as to render them almost unmanageable.

I have hitherto considered that the equable temperature of a well-protected bee-house would preserve even wooden hives from this very great evil, whilst exposed straw hives would be equally exempt, owing to their being so much better non-conductors of heat than those made of wood. I have, however, now lying before me a letter from a distant correspondent, who asks advice in this very emergency; the hive in question being both of straw and wood, and having the advantage of being placed in a store-room, whence the bees obtain access to the open air through wooden blocks substituted for bricks in the external wall.

What enhances the difficulty of this question is the fact that results vary so much in different hives under apparently precisely similar circumstances. Of my own twenty-six stocks (all of which are on the non-ventilating system), about twenty are in perfectly good condition, whilst in two of the remaining half-dozen, a great number of bees have fallen victims to disease engendered by excessive moisture.

In answer to "A. W.," I stated my intention of trying unpainted boxes not exceeding seven-eighths of an inch in thickness. I may now say that the results of this trial are so far favourable.

On the other side of the Atlantic, where the evil is even more severely felt than with us, owing to the universal employment of wooden hives and the extreme severity of the northern winters, the question is deemed an open one, as may be seen by the following quotation from Mr. Langstroth:—"The best apiarists are still at variance as to how much air should be given to bees in winter, and when their hives should have upward ventilation, or not." He recommends upward ventilation during winter, the bees remaining in the open air; whilst Mr. Quinby advocates their being placed in a dark room, either inverted or with the crown-boards removed.

In opposition to both these authorities we have Mr. Harbison an excellent practical apiarian, who has taken out a patent for

* I have, however, never gone to the extent of Dr. Mackenzie, who recommends that wooden hives should be 2 inches thick.

the use of straw mats, which he applies internally at the top, sides, and back, removing the two side frames and the glass from the back window to admit of their introduction.

Borrowing a hint from this last-named gentleman, I intend trying the effect of lining the interior of wooden hives with rush matting, which is the most appropriate material I can think of, and which being a pretty good non-conductor may have the effect of abating, or possibly doing away with the evil. My frame-hives have sufficient space at the top, back, front, and sides to admit of its temporary introduction during winter, whilst any new hives may be made sufficiently large to admit of the matting becoming a permanent institution. In due time the result of this experiment will be communicated by—**A DEVONSHIRE BEE-KEEPER.**

SUPER-POSING.

WHEN I transmitted you my last remarks, page 227, on the above subject, it was not my intention to have again alluded to it; nor would I have done so but for the very opportune letter addressed by your excellent correspondent, "B. & W.," page 247, to his friend, "A DEVONSHIRE BEE-KEEPER," as to the "solution of the super-posing problem."

"B. & W." first treats of bees vacating supers for their stock-hives, and, however sensible his remarks are, they do not apply to the discussion under review. He next takes up the applicable case of the union of stocks at the end of the season, with a free passage upwards to the combs, which was duly stipulated for in my advice to "A. W." at page 78; and, with the exception of the dubiety expressed as to the desire of "A. W." to get his bees to ascend, which a glance at page 38 would at once satisfy him was the soul of the query, his surmise as to the probable result is quite in unison with my actual and universal experience; and here, therefore, much pleasure in placing him on the ascending side of this controversy, and compliment him as the only southern apianan writing on it who seems to possess a clear idea of the first principles of the storing system.

In discussing the subject some of your correspondents, apparently not practically acquainted with storing, conform to the procedure of bees in anthers—one thing with these movements, in stock-hives another and quite different affair. The skilled apianan, taking advantage of their undeviating practice of storing honey at the very topmost part of the hive, places thereon a still higher "alp" in the shape of a shallow super, admitting by means of contracted end or other communications the honey-gatherers only; studiously excluding as far as practicable, for obvious reasons, the royal mother, greedy drones, and main body of the bees; and, by means of this artificial adjunct (totally unfitted from its shallowness for a stock), he removes the finest portion of the store for his own benefit.

On the other hand, quite the opposite course is pursued in uniting stocks in bar-hives. The slides or crown-board (same thing as to result), having been withdrawn from the under colony, thereby affording a free and uninterrupted communication between every comb, the lower invariably ascend and amalgamate with the higher, as "B. & W." so shrewdly guessed, being one hive under one queen and government. Indeed, I may mention it is the practice of many of the famous Ayrshire bee-keepers placing their swarms in two of their octagon-hives at the out-put; and I have myself found the combs wrought from the bars in the upper box resting and attached to the bars of the lower, the thickness of the bar the only separation between the two combs. On the union being effected, if at the end of the season, as in the case before us, the bees must naturally be puzzled to find to them the strange anomaly of honey stored in the centre of their hive (formally top of the lower), and thinking it extremely bad generalship to leave so valuable a portion of the commissariat unprotected without the lines, live upon it, calling in requisition the transport service, and move the remainder within; and guided by the same meretricious instinct that causes the dormouse to retire at the approach of winter to that snug nest where she had previously laid up her store, so the bees similarly retire to the upper portion of their hive, where their store had been placed in anticipation, and there subsist the long winter through on the fruits of their industry.—**A RENFREWISH BEE-KEEPER.**

P.S.—Since writing the above, I have just seen your issue of the 7th inst., and not having "B. & W.'s" capital treatise at

hand to refer to (a friend having borrowed my copy), I can hardly believe he really recommends therein attempting the union of stocks in bar-hives without first removing the top-board, and only allowing so contracted an aperture for communication, as afforded by "a one-inch or two-inch hole in the top of the lower hive."

If "The English Bee-keeper" so fences, this may partly account for the rather hazy opinions put forth by English apianans as to the results of the union of stocks.

"A STUARTON APIARIAN'S" query regarding the uniting two bar-hives, and his allusion to his "never having removed the top-board," surely savour of irony. The taking off such from a "Stuarton" hive would be a task somewhat akin to that imposed by our Scotch proverb of "Taking the breeks off a hielman," for the very ostensible reason that they were never on; the slide serving the purpose in the one case, what the kilt does in the other.

QUEEN BEE'S STING—INTERBREEDING—UNFILLED LIVES.

"A DEVONSHIRE BEE-KEEPER" has certainly shaken my confidence in what I said as to the unmistakability of the queen bee's sting. I could not now persist in the conviction that it was not her mandibles which surprised me, although I presumed at the time the twinge to come from their antipodes. The moment I experienced it her release was instantaneous, but then the insertion of her sting would be instantaneous, and certainly that instrument was not left behind, otherwise I must say her jaw was severe.

The nearest bees to those of the cottagers I mentioned were his Grace the Duke of Marlborough's, about a mile off; mine are nearly two miles away.

Bees would certainly not deteriorate where from forty to eighty hives were kept—their relationship would be so divided with a constant renewal of lives going on. It is where a few only are kept that a depreciation of breed would take place, and only a few were kept by the cottager. The old barbarous brimstone-pit system of "taking" the annual progeny was the rage; and some three or four old, very old, painted straw hives fixed upon the front walls of the house for ornament, were only kept for stock; and what stamina of bees to expect from these I need not explain to "A DEVONSHIRE BEE-KEEPER." Last winter told its fatal tale upon them.

People often exclaim to me, "What fine bees yours are!" and I wish I could procure a swarm of the progeny from "B. & W.'s" Tasmania, all the way from thence, to cross with them. I am quite sure mine would not become less in consequence. But if I had lived in Tasmania some years, and allowed myself but three or four old skeps to breed from, notwithstanding the ever-so-near vicinity of "B. & W.'s" drones, I should undoubtedly have found my bees become perceptibly smaller than those which I now cultivate.

As to the unfilled hives, everything I write is from my own experience, and three of that ilk were not profitable to me. Why I like my hives to be quite completed in their combs by the autumn is, for the bees to be quite ready for our early excrement bloom to work the honey in the supers, instead of expending it to complete their combs in the skeps. If I do not make a market of my early honey, the late—viz., the lime honey is seldom of use for that purpose; for here, in fine, hot weather when the limes are in blossom, a dark honeydew is apt to be engendered on the beech trees, which the bees collect and disfigure the sample.—**UPWARDS AND ONWARDS.**

* *Anglais, Trowers.*

OUR LETTER BOX.

CANARIES (H. M.).—Your greenhouses will be an excellent place for the breeding cages. These (3 feet by 1 foot by 1 foot) are not too large.

ASKED ON TROWERS (H. H.).—Any of the horticultural builders who advertise in our columns would supply you with a plan, if you send them particulars of what you require.

PAPER CLOTHES (A Constant Reader).—We never before heard of such a manufacture. Collars for ladies and gentlemen are made of canalised paper at a price cheaper than the cost of washing those made of a more durable fabric; but we do not know any one who would be bold enough to wear a garment made of paper. If there is such a patentee as you say, we have not heard of him. Why not go to the Colosseum and hear the lecture?

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last thirty-five years, the average highest and lowest temperatures of these days are 43.8° and 39.7° respectively. The greatest heat, 57°, occurred on the 1st in 1852; and the lowest cold, 8°, on the 31st in 1857. During the period 134 days were fine, and on 164 rain fell.

PRESERVING ICE.

FROM crossing flowers we pass to a cross on the ice, which is the more natural amusement in the winter.

I was beginning to think that the practical thinkers on the rules and methods for keeping and for wasting ice, had been so chilled with what had been said of the ways of Nature with ice, that we should have no breakers, no skaters to speak of, or no sliders either, till the ways of Nature should have been forgotten once more, and our own ways might then be set up with less risk of being chilled by adverse criticism. I say, I was beginning to get into the dumps with myself for not having pounded the subject more completely, as they do the ice at storing time, in order to have made the impression which was sure to end in printing it. But then I thought the lull might have been caused from the fact, that the practice, of the principle, of keeping ice was kept out of view in the explanation of the principle, or natural law, which governs the whole question.

There is no question of the day, and none of the darkness of night, certainly, in which it is more essential to hold closely to the natural laws which govern and which practically affect the subject of discussion, than the question about the preservation of ice. I did propose to myself that another chapter was necessary for the explanation of the practical application of the rules which we had to deduce from the laws referred to, and so explained. But the ruling passion of the mad craft of crossing flowers had been more powerful with me, and kept me off the ice chapter to this very day. But on this day I had to answer some questions about the practice of keeping ice in stacks out of doors like hay-stacks, or corn-stacks, and ricks, if there is a difference between them. They were short questions from an "OLD SUBSCRIBER," who is in a young situation, or one which was new to him not long since, judging from the name of the place and the county he wrote from. The ruling passion was still uppermost till the last week's Number of this Journal came in. But just hear the answers I had ready on the paper about ice-stacks when that Number of this Journal came in.

Ice-stacks were the next expedients after the failure with ice-houses, and it was not necessary to bring them into the discussion of the causes of that failure. Ice-stacks out in the open air like corn-stacks, being surrounded on all sides by currents of air, keep ice from melting not nearly so fast as where the best attempts for excluding currents have been adopted—that is to say, in ice-houses. In order to understand properly where ice-stacks would be best placed, you have only to consider two simple laws of Nature which refer to this question.

First. *The law of damp, so to put it.* Keep damp as much as is possible from ice, and you have done all that can be accomplished on that law, or side of the question. Keep it also as much from heat as is possible, and then there is no more possibility of assisting the keeping of ice. The law of heat being the second law referred to. Then the question is this—

Is damp more likely to come into a deep, low hollow in a plantation, or under trees, than into an elevated position in the same plantation, or under the same trees? The next question is like it. Is heat more powerful, or greater, in an unsheltered hollow facing the sun, or on a hill side with a south aspect? And the third question is this—Is the heat of the air or sun less on the north side of a hill, or on the opposite; and in which of all the positions does the law which governs the melting of ice—the law of currents in the air, get the greatest play or power to prevent damp, supposing damp to be only ten times more destructive to ice than heat?—that is to say, so many degrees of damp heat is only ten times more destructive to ice than just as many degrees of dry heat. But in reality the comparison is more near seventy to one than ten to one, and 50° of damp heat will assuredly consume ice more than seventy times faster than 50° of dry heat, provided the air is in free motion at the time.

The whole subject of keeping ice hangs on these few questions. Surely no one acquainted with country life can feel any difficulty in saying in which of the positions stated the sun has less force, and where the winds blow the keenest. The due north of a hill, bank, or building, free from shade or shelter, is where the heat or air has less force for melting ice. But the wind—the source of the law against damp—having most power at the top of a hill, bank, or brae, keeps the ice-stack just so much from the top as will allow the shadow of the summit to pass over the top of the stack, and no more, and you may safely say that is the best place for it, in the eye of science, or in theory: practice must, however, determine how nearly the best place for you or them.

In all this, and in all that I have said about the natural principle of preserving and of wasting ice, I do not, or did not, express a single opinion, except in the very last paragraph about the drain from the ice-house being converted to an air-drain. All that I had advanced was either from natural law, which none can gainsay, or from my own practice, not of a year or two, but of thirty-two years' full practice, and part of the time more practice in one year than some have known in the course of a life-

time. Then, to bring in mere opinions against facts which cannot be controverted is departing from the question.

My good and honest friend, Mr. Robson, is wrong altogether. He first misunderstood the drift of what I said about the natural conditions under which ice is either saved or preserved, and he is out altogether in his own memory about ice-stacks and old sayings on that head of the subject, and I can put him right from a more tenacious memory.

He says ice-stacks were discussed in "London's Gardener's Magazine" as early as 1824. No such thing; the Magazine was not commenced till the beginning of 1826, and for the ten years succeeding there is not a single word in it about keeping ice in stacks; and, writing from memory, I do not recollect that the subject was ever discussed in the Magazine at all. Mr. Robson, however, is a most useful man; for he comes down on us fast Ninruds, and puts on the drag when he sees a steep hill, although he may be "puzzled," as he says he is, on the subject of our gradients. He is as good a gardener as either of us can claim to be, and is as honest a man, and as unassuming too, as ever stepped in shoe-leather, and he always puts his objections free from all personalities—and that is just what I want in my old age the rising race of writers to do on all occasions, no matter under what provocation they may take to the pen way. All the practice, honesty, and fair dealings in this world, however, go but a very short length of tether on the side of any man or subject who or which has no more than the best and most sound opinion to bring in aid of fair discussion. I would not give a Ribston Pippin for the opinion of the best man under the British Crown, if I had the value of a Collin to set against it from any known principle or law of nature. Indeed, although I shall not live to see it, civilisation is not far from the point at which man will cease altogether from intruding his private opinions upon public discussions—facts and principles must then go hand in hand to solve all difficult questions.

Yet I shall give an opinion without putting more stress on it than is here asserted. I think that I have read every word that was worth reading in the English tongue about keeping ice, and it is my firm opinion the best thing I ever read on the matter was that article on ice-stacks in the last Number of this Journal—I mean that which is headed "An Economical Rustic Ice-Preserver," and signed "W. Earley, *Digswell*." I never recollect having seen Mr. Earley's name in print, and I have not the least personal knowledge of him, so that considerations of that kind can have no hold on me; but such "considerations" never go with me farther than to prevent me telling a man he was a fool if I thought him so. The whole essence and the secret of all that has been said about ice-keeping are down firm as ice in July in that article, or else I am no judge in the matter.

In the first place, it is the first article in our language in which the great and only fault of the first American way of preserving ice, as explained by Cobbett, is avoided. In the second place, the plan which Mr. W. Earley explains is a cross-seedling between Cobbett's ice-house and the more recent English ice-stack, and the seedling possesses the good properties of both parents without the faults of either; and in the third and last place it seems to me to show signs of being the head of a new race of seedlings as it were, which, being so round and so compact already, the florists of this cooling fancy will have many generations of seedlings from it ere they can be said to have any improvement on the parent of the race.

Cobbett's ice-house has been all along approved of as the best mode for keeping ice; but it had a fundamental error in it, at least in our climate, and all our English ice-stacks have hitherto been made on a wrong principle; but they, the ice-stacks, were a great improvement on the more wrong principle of the common ice-house. Those who do not know how Cobbett's ice-house was made may now see exactly how it was, only that it was more permanent and more costly than the "Rustic Ice-Preserver" of Mr. W. Earley.

Cobbett put in a long row of posts in a circle, and another row of posts in another circle, 2 feet or 3 feet, I forget the exact figure, out from the first row, and stuffed the interval between the two rows of posts with straw; he also braided, or tied, the tops of both rows with sea-tangle, and he put on a beehive-like roof, or say as nurserymen pack hampers of plants, a very conical top, which was very thickly covered or thatched with straw. As far as all that went Cobbett's plan was the very best yet hit upon; and in packing the ice in it I used a very deep layer of straw over the more deep drainage, which was

rough wood and faggots on it. The bed of straw soon rotted from the melting, and, as in the pent-up ice-house, the damp held about the straw much longer than it would without the straw, and the confined air was saturated into the state of vapour—the grand and arch destroyer of ice in all places and climates, above ground or under it, and Cobbett had no means for letting off this vapoured air—no ventilation in fact; all that error has been avoided in the "Rustic Ice-Preserver."

The error in our ice-stack has been the laying of the straw covering on to the body of ice without the shape of the stack being such as to prevent the rotting of the straw by damp. If you could make just a sugarloaf or cone-like ice-stack, and put the first lining of the covering of "drawn straw," as they use it in thatching, and straight on end, the chances of rotting the straw from the melting would be at a minimum, and the rest of the covering might be of tumbled-about straw—or dry leaves, which are still better over a straw lining. But the best plan of all is not to touch the ice-heap with anything whatever, and to have a small opening at the top of the cone to let off vapour, if it ever came. I finish by congratulating the inventor of the "Rustic Ice-Preserver."

D. BEATON.

TREATMENT OF NEGLECTED CAPE BULBS—STEPHANOTIS FLORIBUNDA.

I HAVE the charge of a collection of Amaryllids and other Cape bulbs in various stages of growth. They have been rather neglected, and I want your advice as to how I ought to treat them. 1st, At what stage of their growth should I report them? 2nd, In what compost? 3rd, In what sized pots? I believe that *Valloia purpurea* requires different treatment from the rest.

What is the lowest average temperature at which *Stephanotis floribunda* will thrive and flower? I have a fine plant of it in a large pot, and purpose placing it in a house averaging about 50° in winter; but which on an occasional night, perhaps twice or three times in a winter, has fallen to 38° or 40°. Would such temperature for a few hours at a time be very injurious to it? and would you advise me to plant it out in the border, as I can do over where the hot-water pipes pass across the house to the far side (it is a span-roof vinery), or to keep it in a pot?—ALICIS.

[*Valloia purpurea* being an evergreen must be watered and kept growing slowly all the winter. The most of the others are deciduous—that is, lose their leaves and remain stationary or at rest for a considerable time; and during that period, if the pots stand in a temperature of from 45° to 50°, and on a moist floor, they will scarcely need any water whatever. As soon as flower-stems or leaves begin to show the pots may be moved, and, after removing the surface soil, be top-dressed with loam and old cow-dung, get watered, and placed where there will be from 5° to 10° rise of temperature, which will cause the flower-stem to come stronger. Such bulbs may be accelerated just like a Hyacinth, but they seldom flower so well as when thus allowed to come when they like, and by marking the first flowering ones a regular succession may thus be obtained. In obtaining fresh bulbs, the pots may have the least thing of bottom heat to encourage free rooting, but the top of the bulb should be kept cool so that little or no excitement should be given until the pot is filled with roots. To help this at potting, only about a third of each bulb should be covered with earth. Now, as to plants in pots and established, the best time to report them is after they have done flowering—say a fortnight afterwards, and then give heat, light, and water in abundance, to encourage growth until the leaves begin to show signs of ripening, then gradually withhold water until the pots are placed in their resting-quarters, and if on a moist floor give no more water as detailed above. Brown fibry loam suits them best, with top-dressings of rich compost, and manure waterings after they begin to move; and, lastly, the size of the pot must be in proportion to the size of the bulb, and its strength—it is best to err on the side of small pots, as the process of growing is sooner finished. A six-inch pot will grow a fair-sized bulb well. For one almost as large as your first an eight-inch pot might be necessary, but extra flowering will ever be procured when the pot is rather small for the size of the bulb. In potting established plants cover three-fourths of the bulb.

The *Stephanotis* will stand very well in an average of 50° in winter, with a rise of 10° to 15° from sunshine. If your house gets often to 38° to 40°, the plant will be sure to die. If merely at that for a few hours at a time, it might not matter much but you will find it better hardly ever to have it below 45°

We lost a promising plant from the house cooling below 40° for several nights. You would have a better chance than we had by planting it over the pipes as you propose, and you might do something by keeping the plant rather dry in winter. Your plant will have plenty of heat in summer as it gets up the roof.]

CULTURE OF KOHL RABI.

IN answer to "WESTMORLANDER," experience teaches that this is much harder and more certain to yield a crop than any of the Turnip varieties. Of the Kohl Rabi, the best variety is the Purple-topped, and its produce of bulbs is commonly twenty-five tons per acre, and of leaves two tons. One and a half pound of seed produces enough plants for an acre. The seed should be sown in February in drills a foot apart, the seed-bed being well dug, and the soil moderately rich. When the plants are full 6 inches high, in May, plant them out in the field in rows 18 inches apart in the row, and the rows 2 feet apart. The soil should be trenched or ploughed deep as for Turnips, and well manured. The plants must be hoed between occasionally to keep down weeds as well as to loosen the surface of the soil. The leaves may be stripped and given to cows, &c., late in autumn, but it is not a good plan to attempt obtaining a second crop of leaves, as it would, even if successful, injure the nutritive quality of the bulbs. These must be trimmed and stored the same as Swedish Turnips. They remain good all the winter if kept cool, dry, and dark.

VISITS TO FRENCH NURSERIES.—No. 6.

MONS. CACHET, ANGERS.

IN bringing to a conclusion these rough sketches of those French nurseries which I had the opportunity of visiting during my late sojourn, I can truly say it has been a labour of love to record the pleasure that I experienced, not only in seeing how things were managed in that country, but also in telling of (not the politeness merely, but) the genuine *bonhomie* and cordiality with which one was invariably received. As I have said before, I have but little doubt but that this was in a great measure owing to my being fortunately under the wing of Mr. Standish, whose hospitality at Bagshot is so well known both by his own countrymen and foreigners; and yet I do think that if one went there with the desire of seeing, as I did, he would experience much of the same sort of kindness.

I do not know that I can more appropriately close these papers at a season when we are watching the opening buds of our Camellias than by a notice of what I must consider the Camellia nursery, *par excellence*, of Europe. A very large word that, it will be said. Yes, truly. And do you leave out all the Belgian ones and the English growers? Yes, as far as I know or can hear, every one of them. The Belgians are rich in small plants, and some English nurseries have very large ones; but for beauty and symmetry I never saw anything to equal Mons. Cachet's. The climate is favourable, and his skill is great, so that one may expect great things, and in this no one, I think, would be disappointed.

I speak of the Camellia as the great feature of this nursery, but there are many other things very successfully done. Ericas, Epacris, and many other hardwooded plants were in abundance. The pots were plunged in beds, and seemed to be doing excellently. Conifers, also, received a due share of attention, as they seem to do in most of the French nurseries; but the glory of the nursery was the Camellias.

The grounds are somewhat narrow, and are intersected in various places by some high hedges, and in the alleys occasioned by these the Camellias were placed. Plants were there from 8 feet to 12 feet high, every side equally furnished; the bloom-buds well set, and the foliage of that rich glossy hue which so marks the health and vigour of this lovely tribe. While in one of the open spaces stood a noble standard Camellia in the open ground fully 20 feet high; and at the end there was a long house into which the plants were put for the winter, and which, must in blooming time be a perfect maze of beauty, and in which was a fine plant of *Agave vivipera* in bloom, and from which, as it is viviparous, Mons. Cachet had obtained two hundred bulbs; while he seemed greatly to rejoice in a quantity of seed saved from *Agave microcantha*, these fine-foliated plants being in much request in France.

It may, perhaps, be interesting to notice (although impossible for us in our cold northern climate to follow it), his mode of culture. The cuttings for stocks are put into pans, and placed in a shady part of the garden without any bell-glass or covering whatever, and here they root in about two months. They are then potted off and placed in heat, where they rapidly make root. During the first year after the plants are worked they are k-*pt* in pots; but after that are planted out in the open ground, in a place suitably prepared for them, and here they remain for three or four years, acquiring, of course, great vigour. At the end of that period they are taken up and potted, and are really magnificent plants. They are then placed in the alleys between the hedges to which I alluded, and remain there all the summer, only to be removed into the house to bloom during winter and spring. As far as I could see, the compost used was precisely similar to that we are in the habit of using here; and any remarks on this, or indeed on the mode of culture to be adopted here, are rendered superfluous by the excellent papers now appearing in THE JOURNAL OF HORTICULTURE from the pen of Mr. Anderson.

We generally find here that the white and light-coloured varieties are more tender than the dark red and rose-coloured ones; and so it is in the open-air cultivation. With regard to sorts I could not discover that there was any great difference of opinion; and that here, at any rate, we and the French are tolerably *en accord*. The larger plants comprise, of course, the older varieties and double white. *Imbricata*, *Princess Bacciochi*, *Montaroni*, &c., abounded. But there was one kind of which Mons. Cachet spoke in the very highest terms as the queen of Camellias, which was quite unknown to me, *Mater Rosa*. It is described as a *veined* rose, beautifully imbricated, of large size, very handsome foliage, and altogether the very beau ideal of a Camellia. I have asked several Camellia-growers if they are acquainted with it, and they reply No. It was procured, as a great many novelties in this tribe are, from Italy, and does not seem to have reached us yet, though I believe my fellow traveller pretty well took all Mons. Cachet's stock. I should be really obliged if any of the readers of this Journal can inform me whether they are acquainted with it. We shall soon see whether it bears out the glowing descriptions given of it, as the plants purchased by Mr. Standish are rapidly coming into bloom.

By-the-by, why has the Royal Horticultural Society excluded nurserymen from showing Camellias at their Camellia show, save only in single plants? There are several things in the schedule at which, as a florist, I should take exception; although where so liberal a list is provided it may seem ungracious to do so. A great step forward has been made, but even now we florists have to complain. Are we greater growers, I wonder, than other folks? and are we like the frog in the fable, fancying we are of more importance than we really are?

And so adieu for a season to La Belle France: and with no one better can I close my papers than Mons. Cachet, or with no better place in one's memory than Angers. Our visit there was a bright spot—a time *ercta notanda*. I cannot hope to revisit it; but I have visions before me of a run through the Rose nurseries around Paris in June next, with the addition to our party of one of the heartiest Rose-growers in England. If it be accomplished, the readers of THE JOURNAL OF HORTICULTURE who have been interested in these stray notes shall have something of it. *Au revoir!*—D., *Deid.*

ICE IN STACKS.

SEEING in this Journal a few weeks since a great deal of writing about keeping ice and ice-houses, most of it written by Mr. Beaton, I was surprised he did not say anything about ice-stacks. As I think he has been very successful in keeping ice in stacks, I should be very much obliged if he would answer the following questions:—Should the ice-stack be open to the wind and the sun, or under the shade of trees and as much out of the way of wind as possible? And if the ice is 2½ inches or 3 inches thick, should it be broken as much as one can, or not?—AN OLD SUBSCRIBER.

[Ice-stacks were the next expedient after the failure with ice-houses, and it was not necessary to bring them into the discussion on the causes of that failure. Ice-stacks out in the open air, like corn-stacks, being surrounded on all sides by currents of air, keep ice from melting not nearly so fast as where the best attempts for excluding currents have been adopted—that is to

say, in ice-houses. In order to understand properly where ice-stack would be best placed, you have only to consider two simple laws of nature which refer to this question. First, the law of damp. Keep damp as much as possible from ice, and you do all that can be done on that side of the question. And there is but one more side to it—the heat side: keep it also as much from heat as possible, and there is no more possibility of assisting the keeping of ice. Then the question is this, Is damp more likely to come into a deep low hollow in a plantation or under trees, than into an elevated position in the same plantation or under trees? The next question is like it:—Is heat more powerful or greater in an unsheltered hollow facing the sun, or on a hill side with the same aspect? and the third question is this, Is the heat of the air or sun less on the north side of a hill than on the south side, and which of all the positions does the current of air get the greatest play? The whole question hangs upon the answer, and surely no one can feel any difficulty in saying in which of the positions the sun has less force, and where the wind-blow the heaviest. The due north of the side of a hill or bank free from shelter is where the sun heat has the less force; but the wind having most power on the top of the hill or bank, keep the stack of ice just so much from the top of the hill or bank as will cast the shadow of the summit over it and no more, and say that is the best place for it. The east side is the next best. Low situations to be avoided; and as in the shade of trees damps come sooner than in open plains, avoid when deep is likely to come. Do not pound the ice, but fill up all hollows and spaces with pounded ice.]

COMPARATIVE COST OF ROOFS FOR LEAN-TO HOUSES.

I HAPPENED the other day to be looking over the cost of lights for "Louises for the million," and found that for lights 12 feet in length, so as to give ground width of a house 10 feet, the price is for a house 20 feet long £20, or £1 per foot run. This, it must be understood, is for the roof only. As I was on the point of building a lean-to house 60 feet long, I was thinking of ordering the lights above referred to; but on finding that the roof only would cost £30, exclusive of railway carriage, I consulted my carpenter, and asked him for his estimate of a fixed roof, intending to ventilate the house by sliding shutters in the front and back walls. It must be understood that I asked him to give me his estimate for the roof only, that I might compare it with the cost of ready-made lights. The difference is so remarkable that it is, I think, worthy of being recorded; and it will, I think, show your readers how cheaply a lean-to house may be glazed even if they pay more than I have stated.

1. 40 rafters, best fir timber, 4 inches by 1 inch, each 12 feet long, and 18 inches apart, chamfered, planed, painted, and rebate formed by taking on a slip of 1½-inch board, 3d. per foot, 8s. each	6 0 0
2. 120 feet of sash for bottom and top of house, 4 inches by 3 inches, planed and painted at 2d. per foot	2 0 0
3. 720 feet glass at 2d. per foot	7 13 4
Glazing and putty at 8s. per 100 feet	2 17 8
Labour in fixing rafters to plates, not morticing but nailing them on	1 0 0
	£11 11 0

By this method of building I have a strong roof with large glass (15 inches by 18 inches—60 feet long and 12 feet wide for the above sum). To purchase lights ready made to form a roof of the same dimensions, I observe, by referring to advertisements of cheap lights I repeat, I should have to pay £30, and even this is really a low price for a roof 60 feet by 12 feet, compared to old-fashioned prices. But what I wish to point out to your readers is the enormous difference between a home-made roof and lights purchased ready made. I therefore refer them to the above estimate, and earnestly advise all those who wish to build verities to form their roofs as I have directed. The supporting walls, as must be the case if ready-made lights are purchased, are at the discretion of the builder, and may be either of brick, stone, or three-quarter-inch boards rebated and painted; there is only one thing necessary—there must be

1. At the present price of timber this is a high charge.
2. Six-inch sash glass can be bought at 2d. per foot.
3. The "trade" charge this price for glazing only, it was the price paid for it done at the Crystal Palace at Sydenham; and clever fellows, I have heard, could do a "trifle" more than 500 feet per diem. 4s. per 100 feet for painting and glazing is a liberal price.

sliding shutters for ventilation, both in the front and back walls. In houses built with these cheap fixed roofs Grapes may be grown in a large portion of Great Britain, without artificial heat, in great perfection.—OBSERVER.

SOIL ROUND FRUIT TREES—MANETTI ROSE STOCKS.

ALL the orchards which I have seen in this county (Somerset) have the ground growing right round the stems, and are constantly fed with sheep and yearlings. The trees apparently do well. Would they be better for the surface being cleared as you recommend "B." last week? What mischief does the grass do? I ask the questions, having an interest in the matter.

I have planted some Manetti stocks to be budded to Roses, many of them have two and three shoots springing from the collar or just above. I shall mulch them with litter to get the bark to run. I want to know if I am to cut back to get young wood, and whether I am to bud the laterals or the main stem? Should not the bud after it has grown be planted below the surface?

I suppose your answer to Apple trees equally applies to ornamental trees, &c., standing on a lawn; if so, what is the plan to hide the bare space? I have forgotten to ask you in the proper place how can I best take out twigs or layerings from the stocks which I wish to bud this year? I have fifty stocks.—EDGARLEY.

[Beyond all doubt the trees in orchards, whether in Somerset or elsewhere, would be more healthy and less choked with moss on the stems and branches by having a circle about 8 feet in diameter kept clear of weeds and grass by occasional hoeing and forking in a little manure on the surface. Some good authorities think that it would not pay for the doing, but we differ from that opinion. All trees are benefited by the air being enabled to penetrate freely to the roots.]

If you bud on unprepared stocks of Manetti you will never be free from suckers. All the buds of Manetti stocks should be cut out below where it is worked when the cuttings are first made. Your stocks are stools, and no stocks at all, and our advice to you is not to bud one of them. They are in their present state a great deal worse than useless for the purpose of budding. Make cuttings of them at once (but it is rather too late), 6 inches in length, and the two top buds only to be left out; cut out all others.]

CHEAP ICE-HOUSE.

HAVING but recently come to this place where there was no ice-house, I was visited by a neighbour during the hard frost of last winter. He described his ice-house to me; it appeared so simple, that I began, finished, and filled it before the frost was over. I opened it in May, and had plenty of ice daily till October. As it is very easy to make, and inexpensive, I describe it in case you think it worth offering to your readers.

On a steep bank I dug a circular pit, 12 feet deep, and 12 feet in diameter. A drain leads from it to a pond; the end of the drain being below the surface. The part close to the pit is of lead, bent so as to form a trap. The sides of the pit are walled with hazel rods and fern, or other litter, stuffed between the earth and the wattle as the work proceeds.

Strong rough poles are used to form the conical roof and covered entrance, which are of the usual form. Two doors of larch branches, between which straw is stuffed when the house is filled complete the woodwork, and the whole is thatched 3 feet thick with heather.—G. G. W.

APPLYING LIQUID MANURE TO FLOWERING PLANTS IN POTS.

In my great authority, "The Greenhouse Manual for the Many," I find weak manure water recommended for Camellias this month; and, on the same authority, I have usually applied it very weak to all plants on the first appearance of their flower-buds. Now, in one of your December Numbers I find you giving a charge never to apply it to any plant from September to May. I am generally a successful grower, most especially bloomer, of the common greenhouse plants. I have never lost a

Camellia; but, although my Azaleas have been most prodigal of bloom, after a year of great profusion I have lost my best plants, although they have been artistically attended to. Do you think this can be owing to the forcing nature of the manure water, or the over-blowing of the plants? I have now a beautiful *A. triumphans* covered with flower-buds—would you advise my thinning them? If you desire it, I should like to give you an account of my success, as an encouragement to my sister amateur gardeners, although it would be a practical refutation of Mr. Anderson's opinion that fine-flavoured Grapes cannot be produced in the same house with well-flowered plants.—A. Z.

[There is no rule without exception. In the months you name, in fine sunny weather, we would help *Chrysanthemums* with manure water; we would do the same with *Cinerarias* and *Primulas*. In continued dull weather clear water would be as good. We would also give weak manure water—weak, mild—to *Camellias* swelling their buds; in dull foggy weather we would rather give it weaker still. In the case of *Azaleas* the manure water should be weak if given at all, and of a cooling nature as that from old cow-dung; very hot manure is apt to injure the plants afterwards. A little rotten leaf mould, or cow-dung three years old, laid on the surface would be safer than much manure water if not weak and cool. Unless excessively thick we would not thin the buds much, but cut all off as soon as done flowering, allow the plant to rest for a fortnight, and then raise the temperature, or take it where the heat is from 55° to 60°, and use the syringe freely to set fresh growth going. We shall be glad of the information and encouragement you offer.]

TREATMENT OF AN OLD WALL INFESTED BY WOODLICE.

THE wall that the Peach, Nectarines, and Apricots are against of which I have the management, is full of large old nail-holes, and the mortar out of the joints 4 inches and 6 inches in a place. There is a vast quantity of woodlice harbour in the wall, the upper part of which wants taking down and rebuilding for about 4 feet, and the lower part pointed. This would make a good job of it, but I cannot get that done. I obtain plenty of good fruit, but, do what I will, the woodlice spoil the looks of half of them. I was going to make a mixture of gas tar and fine-sifted coal ashes, and put something that would mix with it, perhaps oil, to make it to the consistency of whitewash, and get a white-wash-brush and slush it into all the holes and joints; but a second thought struck me, that when hot weather came the gas tar would injure the foliage of the trees. Please give me advice, if that will not do, how I can take proceedings against them? All sorts of trapping I have tried, and shall still follow up; but trapping after the fruit begins to ripen will not save the fruit, for they eat holes at the stalk of the fruit, and there remain in them. There are only a few stragglers to be caught then.—WORCESTER.

[We do not see how you can do well without fresh pointing such a wall. If the tar had been applied early in autumn it might have done, as the smell and ammoniaical fumes would have been pretty well gone before the trees came into bloom and leaf. Now it would not be so, and every spot of tar that lighted on the tree would be injurious, and the fumes would be so too. Even tar, however, would not fill the joints, and the woodlice would get there as soon as the tar was hard and inodorous. The nail-holes might be thus filled; but nothing will do for the open joints at the upper part of the wall but fresh pointing. As a makeshift, the following is what we would recommend:—Get a large pot and a moveable fire near the wall, unvail the trees, and lay them in bundles a little from the wall, wash the wall from top to bottom with water near the boiling-point, injecting it with a syringe or engine into every seam or crevice. That will pretty well do for all live vermin and eggs too. Then make up some linewash with fresh hot lime rather than that from top to bottom, so that it will run into every hole and cranny. This would be too light for the well-being of the trees, as the reflection of heat would be too powerful; but this is merely intended as the ground colour, and for filling all the holes. Then make up linewash of the usual consistency, but to every three parts of hot powdered lime add one part of sulphur, and one of dark Roman cement. This will make the colour much darker, and render it more adhesive. We may consider that after this

there will be no sow bugs to speak of in the wall, but there may be at the bottom of it. To prevent them climbing as the weather gets warm, run a bush along the bottom for 6 inches wide with coal tar, and with a fourth of oil in it to keep it moist. Whenever it get dry and inodorous repeat the process, and trap with all enticing things at the bottom of the wall.]

LONGFORD HALL.

LONGFORD HALL, the seat of John Ryland, Esq., is a modern mansion, situate at Stretford, on the great flat of land which commences at Manchester and extends to Altrincham in Cheshire, a distance of nine miles in a southerly direction. This vale is about seven miles broad. The land is in many places light and sandy, producing excellent crops of vegetables, which are grown largely to supply the wants of the citizens of Manchester.

I had occasion to visit Longford Hall a few days ago, to see and have a friendly chat with my old friend Mr. Adams, the gardener there; and though at this dull season of the year there was not a grand display of fruits and flowers, yet I saw so much and so many good points in gardening, that I was tempted to take notes, and am now writing them out for the benefit of the readers of our JOURNAL OF HORTICULTURE. I like to visit a garden in winter, especially a garden like that at Longford, where there is a large quantity of glass-covered structures. The gay conservatories show a greater contrast to the deep repose of the flower garden, and the early-blossoming Vines, Peaches, and Nectarines, &c., give a pleasing expectation of early fruits, whilst the open walls and orchard trees are all in a naked quiescent state.

At this time of the year we do enjoy our greenhouses and fruit-houses a great deal more than in summer, for the simple reason that the plants are in action, giving us the hope of early fruit; but in summer our attention, admiration, and enjoyment are divided almost equally with the out-of-doors productions of a well-managed garden, as with the hothouse department.

It is somewhat difficult in such a large place to choose a good starting-point in describing it. Perhaps the best will be where I entered the long range of forcing-houses. The entire length is 470 feet, divided into six compartments. The gardener's comfortable cottage is at the west end. I wended my way there, and very conveniently there is a door opening from his house into the range of houses. Through that door Mr. Adams conducted me. The first house is for the growth of Peaches and Nectarines. This house, 115 feet long and 15 feet wide, is a lean-to, and had evidently been put against the wall long after the wall had been built. The trees are old, and have suffered greatly from untoward seasons, but since they were covered with glass the wood has improved, and is now thoroughly ripened and thickly covered with blossom-buds, showing the great benefit these trees have received from being covered with glass. The front glass being upright, young Peach trees have been planted near to it, and a trellis made to train them to. This trellis is a segment of a circle, and is not raised too high; therefore, the trees will never shade those on the back wall to injure even the lowest branches. The object aimed at here is to obtain as much fruit as possible from the space covered; hence even the pillars that support the roof are clothed with Vines which have grown remarkably well, but when the Peaches have filled the trellis I think these Vines will shade them too much, and will have to be removed. The next house is a Peach-house, also 120 feet long, and the same width. It is planted similarly to the first, only on the front trellis standard Peaches have been planted by a former gardener; and in order to bring the heads down the long stems are sloped in a slanting direction sufficiently to spread out the branches to the trellis, giving them a rather odd appearance, but they have nearly covered the trellis, and are very healthy, producing, I was informed, very excellent fruit. This house is just started forcing, and the Peaches will soon be in blossom. The adjoining house is a lofty greenhouse put up to break the uniformity of the long range, and is used to force Azaleas and Camellias into early blooming. Passing through this we entered into a large viney 43 feet long and 21 feet wide. This is a noble house, and is well furnished with healthy young Vines four or five years old. The Vines are all planted inside. A broad walk leads down the centre, with pillars on each side to support the roof. A Vine is planted to each of

these pillars, and the roof is covered with Vines, one to every rafter. On several of these there were hanging many bunches of fruit, chiefly Muscats, when I saw them on the 16th of January this year. On the border I observed a considerable number of Figs in pots loaded with young fruit, which will be very early in perfection. Apple means of heating this large house are provided. The hot-water pipes are 6 inches diameter. A double row of ascending pipes with an under return-pipe are laid on short pillars near the front, and a double row at the back. When in full fruit this house must have a rich appearance. The Vines are very strong and healthy, and appear to be quite at home. The front wall is built on arches, which admit the roots to travel outside when they need that extension.

The three adjoining houses, each 50 feet long, are all vineries also, forced at different periods so as to produce fruit in succession; but inside there are pits, which are used for succession Pines. In order to give the rafter Vines their needful rest, they are brought down, pruned, and laid lengthwise close to the front windows, which are kept constantly open, except in very severe frost. To keep the cold wind from blowing in, a second row of lights is fitted up about 15 inches from the real front windows: upon these a long broad-enough board is nailed, and that board forms a very useful shelf to place low plants upon.

Around the Pine-pits there is a walk, and at the back a border in which Vines are planted. To give these a check and a rest they are, after being pruned, brought close down to the border, and whilst at rest are covered with mats; the cool earth and the covering keep them quiescent enough during the winter months. By these contrivances the houses are made almost doubly useful. Pines and stove plants are grown in them all the year round. At the time of commencing to start the Vines the extra lights are removed and the real front lights closed, and then the Vines gradually begin to push their buds, and when sufficiently advanced are at once tied up to the rafters. All the Vines throughout the whole range are pruned on the spur system. The understratum of all soil on the borders of all these vineries being a very thick bed of sand, and that well drained, there is no stagnant water: hence there was no necessity to raise the soil much above the general level; but a gentle slope is given to the border for the purpose of throwing off heavy rain, as well as casting more of the heat from the sun.

This finishes my remarks on the united long range of houses. On emerging from the farthest door we came upon a small propagating-house and a small fernery, both very useful for their respective purposes. At a right angle with the long range, and a sufficient distance from it, there are two houses built expressly for the purpose of growing Melons and Cucumbers. When I was there they both were occupied with the latter in bearing. The form of these houses is a rather steep span roof; I do think a lower elevation would have been better. There is a five-foot walk in the centre, and borders 3 feet wide on each side. In these borders the Cucumbers are planted in the richest soil that can be made; and, in order to supply ammonia to the air, there are troughs fixed on the pipes filled with water and horse-droppings from the stable; the gaseous matter given off not only feeds the plants but keeps down the red spider. There are four pipes to give top heat and others under the borders to give bottom heat. Excepting the sharp angle of the roof I think these the best houses for growing these kind of fruit I have seen. I must also think that more piping for top heat would be an improvement, more especially during the winter months.—T. APPELEY.

(To be continued.)

CYCLAMEN HEDEREFOLIUM AND NEAPOLITANUM.

IN THE JOURNAL OF HORTICULTURE for December 3rd, page 183, there is a notice of the two Ivy-leaved Cyclamens, *C. hederifolium* and *C. neapolitanum*, the former blossoming in the spring, and the latter in the autumn. I shall be much obliged if you or any of your correspondents will inform me by what characters the two species may be distinguished from each other, in addition to the difference of their time of blossoming.

A Cyclamen which has always been considered *C. hederifolium* grows, or did once grow, at Bramfield, in Suffolk; and a gentleman who many years ago brought the plant from that locality, and who has ever since cultivated it in his garden, obligingly sent me in May, 1860, two roots which he had raised

from the original stock, informing me at the same time that the plant blossoms in the spring, and that he had no remembrance of having seen it blossom at any other time. But to my great disappointment the roots he sent me blossomed in the following autumn, and, passing over the spring, they blossomed again last autumn, and the blossoms and the leaves they produced appeared so like those of a Cyclamen I have long cultivated as *C. neapolitanum*, and which I believe it to be, that hitherto I have failed to discover any difference between them.

That the Bramfield Cyclamen blossoms in the spring is confirmed by the description of Sir James E. Smith, which accompanies the figure in "English Botany;" but he adds that in a cultivated state it sometimes blossoms in the autumn. This statement, together with my own experience of the roots from the Bramfield stock, has suggested the query whether the two plants are really distinct species; whether the plant which in Italy invariably blossoms in the autumn, does not in the colder climate of England sometimes blossom in the spring. In such cases it may be supposed that the heat of the summer has not been sufficient to form the latent flower-buds in time for their development in the autumn, and that, therefore, the blossoming has been retarded till the spring; and it may be that the roots having acquired this habit generally retain it, or retain it until they are removed to a warmer situation. In his "English Flora," Smith gives April alone as the time of flowering of *C. hederifolium*; whilst our more recent Floras, I believe all of them, give the autumn as the only time. Smith does not appear to have known any other locality than that of Bramfield; but a Cyclamen which the authors of our more recent Floras consider identical with the Bramfield plant, grows wild at Sandhurst, in Kent, where, as I am informed by a gentleman residing in the neighbourhood, and to whom, also, I am indebted for roots, it invariably blossoms in the autumn, never in the spring.—HALESLEIGH.

[There is little doubt that Sir J. E. Smith, Lindley, and Don, all three described in some of their publications the Cyclamen neapolitanum of Tenore for *C. hederifolium* proper of Clusius; and there is as little doubt that Tenore, finding their mistake, applied the name neapolitanum to the one which has been universally cultivated in England as *hederifolium*, and which is the same as the identical English Cyclamen found in Suffolk and in Kent; but in middle Italy alone, it is said, is where it is quite at home. However, Clusius's original Cyclamen *hederifolium* (*Cyclaminus hederifolius verno tempore flores*) is said to be as common at Naples as neapolitanum; therefore there is, and has been for some time in England, not only the mistake as to name, but two plants have been confused the one with the other. Our British Cyclamen is certainly the true neapolitanum of Tenore; and if Clusius had not, nearly two hundred years before, named the spring-flowering Cyclamen of Southern Italy *hederifolium*, our British plant would have better deserved that specific name. There are only three European Cyclamens considered as distinct botanical species by those who have had good opportunity of studying them and long practice in their culture, and the three are more or less Ivy-leaved. First in order is Clusius's spring-flowering Calabrian plant; the second is Linnaeus's European, a native of Northern Italy along the Alps; and lastly, this plant of middle Italy, called by Tenore neapolitanum, after Naples, his own town, round which it abounds, and where the northern limits of Clusius's *hederifolium* are said to rest.

After they have been long in cultivation they vary much from seed; and as by seeds only they can be increased, their botanical distinctions, which are few, are soon so much blended that the original descriptions would now be of little avail. Neapolitanum is the most varied in the leaves, some being quite as in the Irish Ivies; some have triangular leaves; some are five-angled. All these variations are not found on one plant; but the seedlings of any plant of neapolitanum will exhibit these diversities; and there is an irregular broad band of white and purple on the under surface of all the leaves in their different variations. The under side of the leaves of the true *hederifolium* is plain purple, as in cum, and only marbled on the upper surface, and the bulb is not nearly so strong as that of neapolitanum. I am still without these three Cyclamens pure and simple.—D. BEATON.]

THE ISABELLA GRAY ROSE.—This beautiful Rose I believe seldom flowers until four or five years old. I have one in flower now (20th January), only eighteen months old. It is a

beautiful Rose, the perfume (though faint), is like the Sweet-briar. The plant I have flowered was grown in a different manner from the rest. I expect to flower all my plants next summer under the same treatment. If I succeed I shall let you know, and also the way I treat them.—JOHN ANGUS, *Gardener, Enniscoe.*

CONDITIONS NECESSARY FOR PRESERVING ICE.

I TAKE the liberty of responding to the invitation of your very able correspondent, Mr. Robson, in expressing my views as to the conditions most likely to preserve ice for the longest period of time, and to note a little of my experience in the matter.

It may be remarked in the first place, that ice is simply water deprived of its caloric or heat; and as soon as its temperature is raised beyond a given point the solid state gives way to the fluid. Keeping this well-known fact in view, one would really think that there could exist but very little difference of opinion as to the conditions necessary to preserve water in this cold and solid form. Evidently, this will be most fully accomplished in proportion as we manage to prevent heat from getting at our stored mass of ice; and failure or success will depend entirely on the conducting or nonconducting powers of the medium with which the ice is more immediately surrounded. There may, however, be great difference of opinion as to the best means of securing such conditions as are most desirable.

Most fully do I agree with Mr. Robson's views (as opposed to those promulgated by Mr. Weston)—namely, that a current of summer air is the most likely thing in the world to get rid of ice at the shortest possible notice. In this respect I remain, as yet, one of the old school. It cannot have escaped the notice of the most superficial observer, that under no circumstances do snow and ice vanish so quickly from our fields and headlands as during the prevalence of a high mild wind; and that frost and snow stick longest to the ground in those "hollows and dells," where most sheltered from a current of air. The great capacity of warm air for moisture accounts for this. Every particle of air, as it rushes along in a breezy day, imparts its heat to the snow, melts, and lies up its quota and carries it away. Nor is it conceivable that a current of air, in the dog days, rushing through an ice-house and playing upon the ice, can have a contrary effect.

It has already been remarked that there can be but little difference of opinion as to the fact, that the best way to preserve ice is to keep heat from it. Surely there can be no surer way of defeating one's object than to allow a current of air, with the heat of summer, to pass through the ice-house. Heat may find its way to the ice through many mediums; and depend upon it, Mr. Robson is quite correct in distinguishing water as one of them, and in recommending double or hollow walls; and besides such a precaution, the outside wall should be surrounded with the most porous material—such as pure sand, and the most complete drainage should be secured all round and below the level of the lowest part of the building, to prevent water rising by capillary attraction. Over and above all, and extending beyond the boundaries of the building, there should be a thick roofing of straw, reeds, or heather, or whatever is the best non-conductor and warder-off of wet.

Anything that most effectively prevents heat by the medium of air in currents, water, &c., from getting at the ice must, in the nature of things, give the best security for its safety. I have had experience of two ice-houses standing close to stagnant ponds, and in which ice never kept well; no doubt moisture by capillary attraction was the cause.

I will conclude these remarks by saying, that I would care very little whether an ice-house were at my command here or not. The nature of a large portion of the ground makes me entirely independent of any such structure, and conditions are afforded which I consider first-rate for preserving ice. To explain, I have only to say that there are immense embankments, in and around our woods, of pure sand to a great depth. There are millions upon millions of loads of sand with which we propagate our plants. There is nothing more required than to choose a well-shaded knoll of this sand, and dig a hole in the side of it something like an ice-house. Into this hole you might turn a water-course; it would all disappear as it ran. Here, then, are what I consider conditions most desirable for preserving ice—perfect freedom from anything approaching to an accumulation of moisture, with acres of the same sand around

the spot. The ice is put into this pit in the usual way. When filled, there are placed over the ice and round the shoulders of the knoll some 4 feet deep of dry straw, and the whole is thatched over to defy wind and rain. A tarpauling over all would be an improvement; but without such the ice keeps first-rate. Here is a lump of ice surrounded with a dry non-conducting medium, and the result is most satisfactory. In what way would a current of air entering at the base and passing off at the apex improve it?

Previously, little was thought of these sand-knolls for preserving ice; and there was only a little put into the pit to be used before that in the ice-house. Any one at all conversant with ice-preserving principles could easily see that such a position afforded the very best security for stored ice. The pit has been enlarged, and from sixty to seventy cartloads put into it, and it keeps far better than ever I saw it keep in any ice-house, and comes in for our late autumn and winter supply.—D. THOMSON, *Archerfield Gardens.*

SOWING ARCTOTIS GRANDIFLORA AND SALVIA PATENS.

A *Subscriber* would be glad to know the height and colour of the *Arctotis grandiflora*, what time the seed should be sown, and whether it would look well in a bed with a border of Sweet Alyssum.

And also, when the seed of *Salvia patens* should be sown to flower in July.

[The average height of *Arctotis grandiflora* may be said to be from 10 inches to 15 inches. The colour is a light yellow; but the plant is not at all suitable for bedding, only as a good knoll to plant on a border of mixed flowers. The spring is the time to sow all plants in general—some few in the autumn, and still fewer at the time the seeds are ripe, be the season what it may. Then the best time of the spring to sow *Arctotis* or any other seeds which require half-hardy treatment, varies in every place in the three kingdoms, and is done entirely under sheer necessity in nine cases out of ten. In the tenth place the man of the place sows all his seed, of this class before February is out, some of them as early as the first week of the new year, because he has plenty of room under glass to keep the seedlings going, and plenty of men to look after them; and the nine persons out of ten go on severally on the same tack, only so much behind. Each sows as early as his means will determine on to the very end of April, and some have to do the whole without a square of glass from the 20th of April to the same day in May. The best time for every one is to sow on the very day on which his or her room and the garden arrangements will admit of its being done. First consider your ways and means, and sow seeds in January, February, March, or April, according to that good old rule.

The seeds of *Salvia patens* to flower in July, should be sown just fifteen months before that July, not one day later. In some places, however, by sowing the seeds in January, and by first-rate work the seedlings, or many of them, bloom in August and September following; but in nineteen out of twenty cases the seedlings are only just showing for bloom as the frost is coming. For all real and useful economical work, *Salvia patens* ought to be sown as a biennial in May to bloom the following year.]

IVY EDGING FOR FLOWER-BEDS.

My employers have been travelling lately in France, and in the gardens of the Louvre and Tuilleries they have seen some beds edged with Ivy. Can you inform me if it is the common Ivy, or what variety it is they use? Also how it is planted, and what is the after-treatment.—WORCESTERSHIRE.

[Your employers had no need to go to Paris to see the common Ivy planted as flat edgings, in-doors or out of doors. Our own nursery reporter explained the plan in these pages six or seven years back, and he highly approved of the plan, which is as old as any of our readers.

Mr. Weeks, the celebrated no-boiler-system man, was the first person, we believe, who made Ivy edgings; and any one may make them any time of the whole year, but the end of April would be the best time. Any kind of Ivy would do, variegated as well as green; and plants from 6 inches out of a

coppice, to 10 feet or 12 feet from a nursery in pots are equally good for the purpose, and the training and trimming are just the same as for Mangles' Variegated Geranium.]

MANGLES' VARIEGATED GERANIUM.

I AM very glad that Mr. Smith gives us hopes of some day possessing a gold-edged Geranium, with all the good properties of Mangles' Variegated one. Some how Mangles' Variegated has been one of my greatest favourites, if not the most favoured one of all, for a great many years. True, there are some now possessing a more clear white margin, and with a more robust constitution, keep better through the winter; but there are none that grow so quickly and cover an allotted space so soon as this one, and few people complain of having too much of it, that I shall be glad to hear of its free-growing qualification being transferred to one of another hue. Flower is a secondary consideration in a Geranium like this, and in fact, is so in all variegated Geraniums; for, with the exception of Brillante, I do not know of any variegated one that does not look better without flowers than with them, while Brillante is the most profuse bloomer I have, but its grey-looking foliage seeming in the distance neither variegated nor plain-leaved, is much against it for effect.

What I admire in a variegated Geranium for bedding purposes is not what I believe florists have been endeavouring to attain. I like a leaf as deeply tipped as will be with pure white, but at the same time it ought to wrinkle, and its edges turn upwards in a cup-shape, and not reflex and turn downwards as most of the plain-leaved ones do, and also many that are esteemed as variegated—as, for instance, Alma, which though possessing a broader margin of white than most others, nevertheless neutralises it very much by the edging turning downwards instead of pointing up, thereby showing the central or plain green part most. I admit there is some merit in Geraniums of this class when viewed as potted plants, or as close under the eye as these plants usually are. This is not the main thing that is wanted in bedding plants; but as I have before stated my views on bedding Geraniums, I will not go over the matter again, but will simply say that I shall be glad to hear of a gold-edged Geranium having the free-growing qualities of Mangles' Silver-edged one being to be had; and I do not despair of an energetic, patient, and persevering cultivator accomplishing this, and whether this fact be accomplished by seed, or subjecting a plant to such treatment by application of some chemical liquid as will induce it to assume the required hue and become permanent that way.

I may also say, that though Mangles' Variegated Geranium rarely produces seed, yet it sometimes does so without artificial impregnation. The first time I observed it doing so was in 1852 or 1853, and the seeds seemed perfect, but I do not remember the result. I have on hot seasons seen it produce occasional seeds, but it is a shy one that way. Neither are seed-pods wanted in the flower garden, however useful they may be to the raiser of new varieties; but I shall be anxious to know the particulars of any case which tends to alter the foliage of a Geranium or anything else; and if the plant in question be induced to put on a yellow jacket, I see no reason why other kinds should not do so likewise.—J. ROBSON.

BLOOMING TOM THUMB GERANIUMS IN POTS.

RAISING BEDDING PLANTS FROM SEED.

I SHOULD be glad to know what sized pots Mr. Fish refers to in speaking of his four profuse-blooming Tom Thumb Geraniums (Dec. 17, page 235). I am intending to purchase a dozen or two young Tom Thumbs this spring, which will probably be sent to me in small pots. In order to promote free blossoming, should they be left in the same pots this season, or at once put into those in which they may remain "a dozen years?" Our soil is a strong heavy clay, in which all plants grow to leaf more than to flower, and are apt to be distressingly rank and luxuriant; therefore the pot system would be especially desirable if moderately small pots would do.

Would such seeds as *Lobelia*, *Citraria*, *Petunia*, *Phlox*, &c., be likely to germinate if sown in pots at the end of February, and kept in a room the temperature of which is seldom under 50°?

I want strong healthy plants for bedding in May or June, but have no greenhouse nor means of forcing. How should it be

managed? In the room referred to they would only have a gleam of sunshine late in the afternoon. Would a lower temperature with a great deal more sunshine suit them better?—FYLTONIA.

[Mr. Fish's plants spoken of are in 14 or 15-inch pots, and are about 1 foot in height. You must not think of such pots for a number of years, or you would neutralise the object you have in view. Suppose you get your plants in March or April in small pots, you might when established give them a shift into five or six-inch pots if they are strong and bushy, and less if they are not, doing this a fortnight or three weeks before turning-out time. That size will be quite large enough for bedding purposes. When you want a few extra large for staring centres, or to make a fine mass as introduced specimens, then you may gradually give them larger pots; and when they come to stand in from eight to twelve-inch pots they will not need repotting for years. Even those in six-inch will do several years without repotting if carefully kept and fresh top-dressed. But for the expense of pots and extra care afterwards in dry seasons, a more brilliant mass of bloom would be produced from Scarlet Geranium-beds if the plants are plunged in their pots.

We should sow all the seeds you name in light sandy soil, a little moist, and but slightly covered with white sand and a little very fine soil in it—say in the first week of March, and place them in the warm room, covering each pot with a square of glass, or a piece of thin paper or glazed muslin—the glass would be the best. As soon as the seedlings in a pot appeared more it close to the window, and give a little more air by raising the glass a little on the side next the light. When more want getting to the window, remove the first, now growing and partly hardened, to the cooler and lighter room. That, however, should range from 40° to 50°. Here they will gradually get more hardened off, and when large enough must be pricked off rather thickly into other pots. It will be as well in the case of *Lobelia* to prick off in little patches, and not to trouble with individual plants. In fact, this may be done with all, each patch containing some half-dozen plants, and these may again be divided as they become larger and can be more easily handled.]

METEOROLOGY OF 1861 AT FROME.

THE past year came in with tears, and the first few hours of its existence it was subject to the wind. Having recovered this slight indisposition, it buckled on its armour and asserted its iron-bound authority, though not with the severity of its predecessor, nor more than the season required to keep things in a healthy state. From the 20th it was unseasonably mild. February came in mild, and continued so the greater part of the month, and with rain two days out of three kept the land wet, and amongst the plants of bedding stuff dan-ping-off was very prevalent, although the wind was blowing hurricanes most of the time. March came in with its well-known characteristics—hail, wind, and rain; and although the atmosphere was mild, owing to a continuance of rain the earth was too cold for the well-being of vegetation. Rain fell on the three first days of April, afterwards it was dry and warm with two exceptions. On the whole, the weather was all that could be wished for, and rapid strides were made both in art and nature. May came in dry and mild, and many that were pressed for room (self included) put out bedding plants and all seemed to go on well till the 8th, when about 2 inches of snow fell, with the thermometer gradually lowering till it reached 33°. Fortunately it remained there, but everything in the shape of protection was laid hold of and made the most of, so that nothing suffered. There was considerably less than the average of rain, which proved an advantage to the crops generally. The low and wet lands did not recover from the past summer and winter till the end of the month. With the exception of a few blighting winds June was a favourable month for vegetation. Up to the present time the crop of hay bids fair to be a light one on poor and low lands. The quantity of rain that fell was somewhat below the average, but being distributed over eighteen days, and not falling in heavy storms, almost every drop was available. No symptoms of the Potato disease are yet visible.

July, as a growing month, was of the very highest order. Seeds with all the complaints came up well and flourished. The weather was not so favourable for haymaking as could be desired, yet there was a good deal of hay put together well. Rain fell on twenty-four days, but in many instances only in slight showers, and often in the evening or night, and, there being a

good drying breeze most of the time, soon put matters to right for the day.

August was the warmest month, which is not generally the case. The nights being warm, the ripening process made rapid strides. The harvest good, and the prospect of a cheap loaf appear reasonable.

Although the average temperature of September was 10° lower than the previous month, and nearly four times the quantity of rain fell, yet nothing could be more reasonable, for both the grass and the root crops, with almost every other crop, had begun to feel the effects of the dry, warm weather of August. The earth being thoroughly warm it sucked up the rain as it fell, and vegetation grew with a rush. There was very little variation in the day and night temperature, and only one frost during the month.

October, as a whole, perhaps its equal may not have been in the memory of man. There was not a single frost during the month, and the fields were as green and the flowers as gay as in the month of September. The temperature has usually decreased from 5° to 6° from September; but in this instance it has only decreased 1° on the day temperature, and the night temperature averaged 2½° higher. Nothing could be more favourable for the maturing of the summer's growth for the next season.

The month of October having been a summer month in temperature, the foliage had scarcely received a tinge of its autumnal beauty and splendour when November entered upon its duties, which have been more varied than usual, and of a most determined character. The tempest and the storm have been at work on sea and on land, and have left many melancholy mementos of their track. Rains have fallen to a greater extent than during any previous month during the year, and with the earth saturated with moisture the monarch of the icy regions issued his despotic mandate, and in the dead of the night asserted his iron-bound authority over the length and breadth of the land, crushing and withering the first faint gleams of autumnal beauty at one fell swoop into winter's cold embrace. The dull, foggy days so characteristic of November, have been but few, which is some little compensation to the gardener for an excess of rain and the severity of the frost of the 18th and 19th.

December, on the whole, has been reasonable and favourable, as being exempt from snow, and rather less than the average of rain; and although the frosty nights and a prevalence of north-east winds were favourable in keeping vegetation in a state of rest, they were very searching to tender constitutions.

—THE DOCTOR'S BOX, Frome, Somerset.

HEATING BY A HOT-AIR STOVE.

AFTER reading Mr. Beaton's plan of constructing a stove for a greenhouse by hot air, I was induced to try if I could make it answer in a small one attached to my garden, which is about 15 feet by 8 feet. The mode I proceeded upon was this—I built first the fire-place, which is about 15 inches wide by 2 feet long, arching it with firebricks and setting the bricks with fireclay; I had all these bricks cut to a "templet," so that I had no trouble in setting them. After finishing the arch I grouted it with a thin liquid of ground fireclay and water, which filled every crevice—that is, supposing any to have been left after setting. I afterwards covered it—that is, the arch, with a layer of sand whilst the liquid was wet: this appeared to make an excellent finish of it, and I feel assured that this arch is as tight

as though it was one solid arch of fireclay. I next built a brick wall on edge on each side of the fire-place 6 inches distance, then a nine-inch wall all round 6 inches from the other side walls. The chambers between these two walls I conducted the smoke through, the flue commencing at the farthest end of the fire-place to the right, passing between the brick-on-edge wall and the outer wall, then by the front under the ashpit, which is, by-the-by, 2 feet below the surface; again under the brick-on-edge wall and the outer wall to the left of the chamber, at the farthest end of which I placed the chimney. I began to be afraid of this answering at first, for there was no draught; on lighting the fire the smoke preferred coming out of the door-plate to travelling so circuitous a route. I persevered with it, and as the flues gradually became dry, so gradually one perceived the draught to improve, which is now excellent when the damper is open. By conducting the smoke in this way I think you get as much heating surface as Mr. Beaton will with his glazed-tile piping traversing the interior of the chamber, which I greatly approved of, but was afraid they would not stand the required heat, and which might be liable to breakage in the joints. Two well-jointed flues cover in the air-chamber, which is 6 inches from the top of the arch to the underside of flues. Is this capacity sufficient to keep up a continual supply of hot air? for at times, especially in very windy weather, there is a back-draught into the chamber. My stove is built 3 feet from the greenhouse, so that I have to communicate the hot air through a sheet-iron tube 9 inches by 3 inches, which I found lost a great deal of heat by being exposed to the atmosphere; I remedied this by covering it with a thick felt, three-quarters of an inch, and covering the latter with a wooden box. The tube on entering the greenhouse is continued at right angles nearly close to the front window to the centre of the house; over this tube I have placed a Waltonian Case, which I supply with hot air from a three-inch upright tube (out of the main tube) which goes into the aperture intended for a lighted lamp. I find that by this means I get a temperature of about 66°, which I should think would be sufficient for raising tender or half-hardy annuals in, or for striking cuttings, &c.; the case has no water in its tank. I have not tested its efficiency, but have no doubt of its answering well.

In the interior of the air-chamber I have placed an iron vessel containing water, about 12 inches long, 3 inches broad, and 3 inches deep. Will this be sufficient for keeping the air moist enough, or will it be too much if water is kept constantly in it? I supply the water by an iron tube through a hole in the flag which covers the chamber.

To what use would you put the top of the chamber outside? the flugs being kept at a good heat as long as a particle of fire remains; they are 6 feet by 4 feet. Would you cover them with glass?—F. M.

[You have made a capital job of it; and now you might have a two-light frame over the flugs for a warm pit, the flugs to be in the very centre.]

NEW AND RARE PLANTS.

PHYLLAGATHIS ROTUNDIFOLIA (Round-leaved Phyllagathis).
Nat. Ord., Melastomaceae. *Lin.*, Octaudria Monogynia. Called also Melastoma rotundifolium. Native of the moist woods of the interior of Sumatra. Another of the justly popular beautiful-foliaged plants. Leaves above, deep, rich, glossy metallic green, tinted partially reddish; beneath bright red.—(*Bot. Mag.*, t. 5282.)

RHODANTHE MANGLESII var. SANGUINEA (Blood-coloured Mangles' Rhodanthe).
Nat. Ord., Composite. *Lin.*, Syngenesia equalis. Native of Western Australia. "The present variety, whether mixed with the species or kept separate will prove a very valuable introduction for ornamenting our flower-beds."—(*Ibid.*, t. 5283.)

BEGONIA KUNTHIANA (Professor Kunth's Begonia).
Nat. Ord., Begoniaceae. *Lin.*, Monocla Polyandria. It has also been called B. lucida and Gaertnia Kunthiana. Native of Venezuela and Caracas. "Few species exceed this in the richness of the colour on the under side of the leaf, contrasting well with the dark glossy green of the upper, and in the size of the flower."—(*Ibid.*, t. 5281.)

DENDROBIUM TRIADEMUM (Three-lobbed Dendrobium).
Nat. Ord., Orchidaceae. *Lin.*, Gynandria Monandria. In-

roduced by Messrs. Rollisson, of the Tooting Nursery; supposed to be native of the Malay Archipelago. Flowers white slightly tinged with pink. Blooms in September.—(*Ibid.*, t. 5285.)

VERTICORDIA NITENS (*Glistening Verticordia*).

Nat. Ord., Myrtaceæ. *Lin.*, Polyandria Icosandria. Called also *Chrysostrich nitens*. Introduced by Messrs. Veitch, from Western Australia. Flowers yellow, in a dense corymb. Blooms in August.—(*Ibid.*, t. 5286.)

VIRESIA XIPHOSTACHYS (*Dagger-spiked Viresia*).

Nat. Ord., Bromeliaceæ. *Lin.*, Hexandria Monogynia. Believed to be from Brazil.—(*Ibid.*, t. 5287.)

BOLBOPHYLLUM BARBIIFORME (*Bearded Bolbophyllum*).

Nat. Ord., Orchidaceæ. *Lin.*, Gynandria Monandria. Native of Sierra Leone. More curious than beautiful.—(*Ibid.*, t. 5288.)

PRUNING THE RED AND WHITE CURRANT.

The directions for forming the Gooseberry bush apply equally to the Currant, and its management as to pruning is much the same. It produces its finest fruit upon the young wood, and it is therefore essential to keep up a succession of young bearing shoots, as the fruit is less good when produced on branches which have borne for several years. The fruit is much improved in size and colour by shortening the young shoots after midsummer, leaving no more foliage than can perform its proper functions, and fully exposing that which is retained to enable it to do so. The Currant is a valuable auxiliary to the dessert when grown upon a north wall, and for this purpose may be trained vertically and spurred-in.

THE BLACK CURRANT.

The form in which this tree should be trained is similar to the preceding, but as its fruit is borne principally on the young wood it is necessary to leave a larger proportion of such shoots at the time of winter pruning. The rule may be to have as many as can be exposed without shading or crowding each other. The Black Naples is the best to grow. The Black Currant does not grow so stiffly as the other sorts, and its branches are more liable to break down when laden with fruit. We find it advantageous to support a few of the branches with short stakes, upon the principle that prevention is better than cure. Fruit is also produced upon small spurs on the older wood; but as these are not abundant, dependance must be placed on the young wood principally. This is more apt to produce suckers than the other kinds, and therefore, the formation of the cuttings must be carefully attended to. We are not aware that any other form of growing it has been tried, excepting the bush with open centre.

THE RASPBERRY.

The fruit of the Raspberry is produced upon suffruticose stems, which spring from the ground either in the same or the previous year. In most of the kinds it is produced upon lateral shoots, which are borne by the previous year's canes. This fruit shrub differs from others of its class in the stems not being persistent, but only of annual duration. They are of an herbaceous rather than a shrubby character. The object of the cultivator should be to get these annual shoots as strong as possible; and, as a multiplicity of suckers are thrown up by all the kinds (but the true yellow Antwerp, which propagates with great shyness), they must as soon as they can be seen be reduced to two or three shoots, which are to form the canes for next year's crop. Care must be taken to secure them from the action of the wind by securing them to stakes, and whenever the preceding year's crop of fruit is over, the removal of the old canes will be an advantage to the young ones. Two or three canes may be tied to a single stake at the distance of 5 feet each way. This distance may startle the amateur, but where it can be given it is a decided advantage; and those who cannot afford so much must bend to circumstances and do with less. At the time of winter pruning the points of the shoots may be shortened a little, and fresh stakes put to them, which completes the process for the season.

The formation of the flower-buds may be retarded, and a late crop of fruit obtained by cutting down some of the shoots to within two or three eyes of the ground. New and vigorous shoots will be produced from the eyes, which will not form their fruit till later than the others, and thus the season of this desirable fruit may be much prolonged. The Double-bearing is a valuable kind, and should have the canes of the alternate

stools cut down to two or three eyes annually. They will thus give fruit almost till Christmas in mild seasons. The finest fruit is in all cases produced upon the strongest and best-ripened canes. Full exposure is therefore necessary to obtain these, and single rows will, on this account, always be found most productive.

THE FILBERT.

A well-managed Filbert should have a clean stem about 2 feet in height, and be free from suckers. The branches should radiate from this central stem, and assume a basin-like form. Its maximum of height should not exceed 6 feet. Filberts in Kent (a county famous for their cultivation) are generally planted as rooted suckers, which are left to grow uncontrolled for two or three years, and then cut down—a vigorous shoot results, which must be headed to the desired height, denuded of its lower buds, and only three or four shoots encouraged to grow to form the foundation of the future head. These must be shortened again at subsequent prunings till the required number of branches is obtained, introducing a hoop into the head, and regulating the distances of the main branches by means of it.

Fig. 8.

The fruit of the Filbert is produced upon the upper part of the young shoots, and upon small branches which spring from the part at which the shoots of the preceding year were shortened. The male blossoms (catkins) are produced separately from the female ones (*fig. 8 A* represents a shoot in which *a a* are female flowers, and *b* the male ones). In pruning, care must be exer-

cised to leave a sufficient supply of these male blossoms for the fecundation of the female ones; and therefore the trees should not be pruned till early in the spring, when their development is obvious. A crop of the fruit is often lost for want of attention to this; and it has been found by experiment that where a tree has itself been deficient in the supply of these, the cutting them from other trees, and suspending them over the females, has resulted in producing a good crop. The pruner must therefore insure an annual supply of these small productive twigs.

In the third year the last year's shoots left to form the head of the tree, will make lateral shoots, which must be suffered to grow during the season, and cut back to short spurs, from which the future bearing-wood is destined to spring. The leading shoot must also be short-ned two-thirds of its length to insure its breaking regularly, and I keep it full of spurs. The subsequent management consists in shortening the young leading shoot, and cutting out old and barren wood, so as always to have a

succession of young, healthy, and fruitful twigs. When the trees become too large every other one may be cut back to within 6 inches of the stem from which they spring; young shoots will again put forth, which must be treated in the same manner as the young tree. Fig. 8 B represents a bearing branch from a Filbert bush which has been pruned.

It is the practice to plant Apple trees and Hops in Kent with the Filberts, but in our opinion light and air are of as much consequence to Nuts or Filberts as to other plants. We are accustomed to see the Hazel grown under a direct canopy of unbragous timber trees; but should we not get larger returns if underwood were grown in one plantation and trees in another? and would not single rows of Filberts, minus large Apple trees, be more productive, and yield fruit of a larger size and better quality under the influence of light and air, than they do when overwhelmed by a dense canopy of foliage? — H. BAILEY, *Nuneham*.

TACSONIA MANICATA.

SUCH frequent reference has been made to this plant recently in our pages, that we think its portrait, history, and description will be acceptable.

It is of the *Natural Order Passifloræ*, and *Monadelpia Pentandria* of Linnaeus. For the following notes we are indebted to "Paxton's Flower Garden," where a coloured drawing of this species may be seen:—

THE GAUNTLETED TACSONIA.— Bracts entire, united at the base, downy, longer than the tube of the calyx. Leaves downy on the under side, smooth on the upper, divided below the middle into three serrated lobes. Leafstalks with several glands. Stipules roundish, toothed in a crested manner.

We believe this species to be unrivalled among climbers, for the brilliant scarlet of its gorgeous blossoms. Placed by their side, the red coat of an English soldier becomes dull and pale. It is a native of Peru, and probably common there, for many botanical travellers have observed it. Humboldt and Bonpland brought some varieties from the city of Loxa; Hartweg says that it is found in hedges near that place; and it forms No. 1294 of Linden's Herbarium, gathered by his collectors, Funck and Schlim, in the province of Merida, at the elevation of 7000 feet above the sea.

It forms a rambling climber, with grey three-lobed leaves and large scarlet flowers, whose tube is almost concealed by three downy bracts, from which circumstance we presume that Jussieu give it the name of the gauntletted (or manicate); it must be owned that the tube of the flower may not unaptly be compared to an arm thrust into a large, loose glove. The coronet consists of two principal rows of short violet teeth, planted on the green tube of the calyx-lining.

Upon what precise ground the Tacsonias are separated from the Passion-Flowers is by no means clear. De Candolle relies upon the former having a very long tube to the calyx, and a scaly coronet; but in this plant the tube is as short as in any Passion-Flower, and there is nothing peculiar in the coronet. Meisner's analysis brings out no more; and it is impossible to gather any distinction after comparing Endlicher's prolix descriptions. Nevertheless, there is something very peculiar in the appearance of Tacsonias, and we trust that in time a real distinctive character will be discovered.

The species was introduced by the Horticultural Society. Its flowers have been produced abundantly in the conservatory of A. F. Slade, Esq., of Chiselhurst, from whom we received specimens on the day of the June Exhibition at Chiswick. Upon comparing them with the finest colours there, nothing could be found to equal them in brilliancy. Others have been less fortunate; and it is understood that the plant is a bad bloomer. We understand, however, from Mr. Ansell, the gardener at Chiselhurst, that it only requires plenty of room, when it soon becomes loaded with flowers. No doubt it refuses to produce anything more than leaves when pruned much, as it must be if restricted in space. In this respect it behaves exactly like other climbers—Bougainvillæa for instance.

FLOWERS OF TACSONIA MANICATA.

A FEW weeks since one of your contributors claimed half of Mr. Beaton's donkey for having flowered the above gorgeous climber. He says, I think, it was like *Tacsonia mollissima*. I write now from memory, not having the Number of THE JOURNAL OF HORTICULTURE at hand; but it occurred to me at the time that your correspondent had never seen *T. manicata*, and I fear there are many others similarly circumstanced. No doubt they have bought plants for *manicata*, and some have bought seed for it; but I know many have been disappointed, and I fear many more will be, especially if they have a bloom like *T. mollissima*.

T. manicata was first flowered at Kennel House, — Sladé's, Esq., by my friend the late John Ansell, the collector for the first unfortunate Niger expedition under the patronage of His late Royal Highness Prince Albert. It was a plant received from the Horticultural Society, and planted out in one of the conservatories, and allowed to ramble and attach itself to the wires near the glass at the top of the house, allowing its laterals to hang down in festoons. There it flowered in 1818 or 1819; I cannot remember which of the two years the first time, but the flowers are not the colour of those of *mollissima*, but are a gorgeous intense orange scarlet—shall I say more intense than a Tom Thumb Geranium? Well, if not surpassing it they are equal to it, if petal was laid on petal. There is as much difference between the two kinds as between an old scarlet cock which had once belonged to a private soldier, but is now found covering some poor wretched mendicant, and the new bright scarlet cock of the Colonel of the regiment, while the rays which are almost black increase this intensity. The bloom is about the size of *Passiflora coriacea*, and is an ordinary greenhouse creeper, but must have room to grow the current season like a Banksian Rose and will flower the next; but the pruning-knife must be kept away from it except to cut back the points or unripined wood of the lateral growth ere the spring growth commences. But where to obtain it true I know not. I called at Kennel a few days since; but found it had grown out of bounds, as Mr. Eyres, the present gardener and steward informed me, and was cut down and thrown away.

Messrs. A. Henderson, Pine Apple Place, correctly described it in their catalogue of 1851, and no doubt it might be obtained of them, or of the Messrs. Rollissons, true; but whoever wishes to have the best of all the *Passifloras*, the most gorgeous greenhouse climber, have it warranted true, and not *mollissima*, plant it out in a mixture of loam, leaf, or vegetable soil, and sand, with good drainage, let it have room to grow one year. They may then claim the donkey's half fairly.—NICKERBOUR.

"JOHN'S GOT SOMETHING TO SAY!"

VARIOUS are the salutations which this exclamatory title will call forth—from the growl of the bilious "Well, say on!" to the humorous invitation of the gentle "Well, John, let us hear." "John's got something to say!" was the speech of a bright-eyed girl to her father on the approach of their young gardener, who was coming towards them, evidently big with some momentous subject. "Th-th-there's some Mushrooms!" (John stammers a bit, poor man.) "Good," says his master, "let us look at the curiosity." They all tramp off to the little back shed where the bed is made up. John very gingerly uncovers it, and points to a little white speck or two about the size of a pin's head. "Yes, so there are; scarcely ready for getting, though." "N-o-o," brings out John with a long-drawn sigh. "Ah, well! never mind—it'll be bigger to-morrow," says the master; but I don't see any signs of more." "Oh, but there is, there will be—there'll be oceans, millions!" (John's temperance is sanguine, you'll perceive.) "Well, John, we'll keep straight with them."

A few days pass over; then a week—a fortnight. John has kept out of his master's way. At last they meet down the garden-path face to face, and the master says, "Well, John, what's become of the Mushrooms?" "W-w-well, (John goes through a bewildered pantomime with his hands and fingers), you see, sir, it crowded capital at first, and then the little beggar began to look sick and brown, and at last when I touched it it fell off;" and John looks intensely disgusted at the impotency of the little agaric. "That was only one, John; where are all the rest?" John begins to hold his head down, and probably to wish he had not been so positive. "I don't know!" at last he desperately confesses. "Well, let us look at the bed," the

master says. They look at it. "What made you water it, John?" "Why, I thought it wanted it." "I don't think it ought to have b-on watered, John, but we'll see." So he looks up every authority in THE COTTAGE GARDENER, from Messrs. Errington and Weaver down to Messrs. Fish and Robson; and they all maintain that the bed should be rather dry than wet. These are all shown to John, who spends nights and nights reading at the kitchen table with a phalanx of volumes before him. He sits the picture of dogged perseverance with elbows on the table, his hand on each side of his head, his fingers thrust through his shaggy hair, and he reads, till, on rising to prepare for bed, he looks so bewil-dered that his fellow-servants burst out laughing, and jocosely inform him that he is about ready for —, the nearest lunatic asylum. But, however, there are fruits from this close application, for he determines to try again, and informs his master next morning that they'll have some Mushrooms yet. The master, full of the milk of human kindness, and knowing that "the best-laid schemes o' mice an' men aft gang a-gley," smiles, and hopes they may.

John makes up his bed this time of horse-droppings that have been thrown in a heap and heated to let off the rank smell and to sweeten them. Before, the bed was made up of horse-droppings that had lain thin in a shed and dried a bit, but never allowed to heat. He beats it firm with a mallet, puts in the trial stick, determined that he will steer clear of the rock of fire; because, has he not read "on no account are you to spawn till you are satisfied that the heat is declining?" The bed is made 10 inches to 12 inches thick. John feels the trial stick every day, and at last pronounces it "all right." He spawns it, covers up with some strong soil, beats it firm, and, as he gives the finishing stroke with the back of the spade, he apostrophises the bed—"There, my boy, you'll do now." John's excited imagination sees innumerable dishes of Mushrooms from his pet bed. He switches about his work whistling and singing; and on meeting his master walking in the garden with a friend, he cannot contain himself, but, in defiance of etiquette, he salutes them enigmatically, with "Th-there'll be some now!" The master smiles, and the friend says, "What marvellous exploit is John up to?" It is explained to him, and, being a fellow of infinite jest, he relishes it. Poor John afterwards remembers with remorseful feelings his impetuosity; for the gentleman, whenever meeting him, very dryly says, "Well, John, how about the Mushrooms?"

Kind reader, do you not see the point of the query? John's pet bed, after waiting weeks and weeks, showed no signs of bearing. He goes to his master, and, scratching his head, ruefully exclaims, "We're done again, sir!" "No Mushrooms yet, John?" "No, drat the Mushrooms. What's to be done now, sir?" "Oh, don't give in, John; try again." And so John goes back to his authorities, and digs in the horticultural field right heartily. He at last discovers what he considers the grand secret—that he let the heat fall too low before he spawned. He communicated this to his master, who said, "Well, John, you must mind that next time. You'd better tell Henry to save you some droppings." So John goes to Henry, and excitedly shouts out, "Henry! save us some good droppings—droppings that'll grow Mushrooms, and don't give us any of your common stuff!" "If you're not off'll —," The rest of Henry's speech is lost by the rapidity with which John vanishes out of the stable, slamming the door behind him. Henry saves the droppings, however. They are spread out and dried a little; and John made up another bed, spawned when the heat was from 75° to 80°. His confident swagger has left him; he makes it with much fear and trembling; and when spoken to about it, he "hopes there'll be some this time." Six weeks pass over; then, to John's inexpressible delight, the bed becomes speckled over with Mushrooms in miniature, which speedily develop into a size fit for table. To see him carrying his first dish in was a sight you would not soon forget. John remembers the lesson, and when visitors come he simply explains his way of making a bed:—"Get your droppings, spread 'em out, turn 'em over a time or two; and then when you think you've got plenty for the bed put them in, the newest and dampest at the bottom. Either tread 'em or hammer 'em till they are as solid as a brick. Make it 10 to 12 inches deep—for, don't you see (here John's voice becomes impressively mysterious), it's almost impossible for it to get above 80° or thereabouts?" So when you're sure as it's about that, make holes in it 9 inches apart; break your spawn about as big as a walnut, soil it down 2 inches, and it'll be O.K." (an Americanism that John often uses—it

is the interpretation of the words "all correct;" spelt, in Yankee slang, "or korrek.")

John cannot quite forgive the backward-in-coming-forward spirit of his charges; for he concludes, irreverently alluding to them in his choice vernacular, "Mushrooms is ruin beggars!"—
WAIT.

WORK FOR THE WEEK.

KITCHEN GARDEN.

THIS department should now be in a state of preparation to receive the spring crops, and every spot of ground to be now trenched or dug. *Broad Beans*, make a sowing in boxes or pots, to be afterwards placed in some warm house or pit. At the same time a crop should be planted in the open ground where it is in good condition. *Carrots*, make a sowing of Early Horn on a slight hotbed, either to succeed the former sowing recommended, or to come in for a first crop. Where the soil is light and dry a sowing may be made on a south border. *Onions*, those who are short of old ones, or who wish to grow some to a large size, should now sow some White Spanish in a box, to be placed in heat. The underground sort to be planted now in the open ground. *Peas*, sow in pots or boxes for planting out in March; sow two crops also in the open garden, one of an early sort, the other of any approved sort which does not come in so quickly. *Radishes*, sow another crop in a frame where there is a little bottom heat, or they may be sown where early Potatoes have been planted; a crop should also now be sown on a south border.

FLOWER GARDEN.

See to bulbous plants, stir amongst them and protect if necessary. Look over and correct the general outlines of ornamental plantations. Break into all straight lines, form bold recesses when space will admit, and endeavour to produce picturesque effects.

FRUIT GARDEN.

Continue pruning and nailing wall trees. Weed Strawberry-beds and fork up the soil between the rows, but not more than 2 inches deep. Destroy all suckers that may have made their appearance in Goose-berry-plantations, and finish making new plantations where required.

STOVE.

Shake out and repot, and place in bottom heat, some *Clerodendrons* in variety to grow on for specimens, and to take cuttings from for young stock; likewise *Aphelandras*. These plants delight in light fibrous loam in a rough open state, a good portion of charcoal both amongst the soil and for drainage, and a portion of coarse sand; and, when the pots are full of roots after their first shift, they enjoy a liberal supply of clear liquid manure. Some of the *Orchids* which are commencing growth to have a little water applied around the inside of the pot, as the collar of the plant is very susceptible of injury from wet. As the days lengthen and light strengthens more heat and humidity may be applied. Reshift any of the *Orchids* that may require it, making use of fibrous heath soil. Set traps for woodlice and cockroaches.

GREENHOUSE AND CONSERVATORY.

The degrees of heat to be applied to these structures will depend in a great measure upon the state of the external atmosphere. If high cold winds prevail, little or no air to be admitted, as sufficient in boisterous weather will force admission through every nook and crevice. Place suitable trellises to the *Tropeolums* that are not already furnished, and pay attention in due time to their proper training. *Ericas* to receive attention as to water, and also a free circulation of air. *Eperisces*, *Correas*, *Polygalas*, *Acacias*, &c., will now begin to bloom freely, and, consequently, require frequent attention in watering. The *Acacias* when in bloom require a liberal supply. Young vigorous plants of *Polygala*, *Muralia*, *Pultanea*, *Oxylobium*, *Dilwynia*, *Eriostemon*, *Chorozema*, *Horra*, *Leschenaultia*, *Pimelea*, &c., should have all their young shoots stopped in due time. Clear off all dead and decaying flowers from *Camellias* almost daily; and should any plant throw out a strong shoot, it is advisable to stop it, so as to produce an equality of strength in the wood and regularity all over the plant. Any early-flowering plants that require removal from the conservatory to be introduced into the forcing pit, stove, or any other structure where there is plenty of heat to produce young wood. Any nice compact plants of *Scarlet Geraniums*, which are intended to make speci-

men plants for vases, baskets, or single specimens on the lawn during the summer, should now be shaken out of their pots and repotted in fresh soil. Give them, if possible, a gentle bottom heat for a week or two until they make fresh roots, and keep a moderately moist atmospheric temperature of from 45° to 50°. After they have established themselves remove them to a light airy part of the greenhouse, to be repotted into large-sized pots or tubs in April, and with the ordinary attention given to such plants they will become splendid plants by June. Apply air daily and freely in favourable weather to all free-growing *Pelargoniums*, and when the flower-buds can be felt on the early plants occasional applications of clear, diluted, tepid manure water to be given. Let every plant have sufficient growing room, and stakes to be applied in due time to those that require them. The varieties of *Kennedy*, *Zichya*, *Hardenbergia*, and *Gompholobium* to be furnished with suitable trellises, and to be timely and neatly trained. The *Cinerarias*, if under-potted, or have been standing near the heating apparatus during the late severe weather, must be sharply looked after, or they will soon become smothered with green fly. Fumigate them in time, and assist those which are coming into bloom with a little clear liquid manure once a-week.

FORCING-PIT.

Introduce bulbs, *Roses*, *Pinks*, *American shrubs*, *Lilacs*, &c., in steady succession. Keep up a bottom heat of 75°, and an average surface temperature of 60° at night and 70° by day, with air occasionally. Keep a watchful eye daily over every article, or some kind of vermin will quickly deprive you of the *Rose-buds*, *Pinks*, &c. Slightly fumigate often, and occasionally apply small quantities of flowers of sulphur in a diluted state with a brush to the pipes when cold, but never apply when the pipes or flues are hot.

PITS AND FRAMES.

Should the weather prove open, begin to water slightly such plants as appear to be suffering from want of moisture. Pick off all damp and decaying leaves. Fumigate with tobacco, but the operation requires great care and discrimination, if the plants are infested with green fly. Pot off the autumn-struck cuttings of *Scarlet* and *Ivy-leaved Geraniums*, *Fuchsias*, and *Verbenas* from the store-pots where there is sufficient room, and where there is bottom heat to excite the roots gently into growth. But where these advantages are not to be found, an increase of stock can be made from the store-pots of *Verbenas*, *Petunias*, *Heliotropes*, &c., by introducing a few of the choicest sorts into some warm, light situation in the houses or pits at work to furnish an abundance of cuttings for striking in a one-light frame made up of well-prepared fermenting materials, which are to be obtained in most places.

W. KEANE.

DOINGS OF THE LAST WEEK.

The changes of the weather have rendered the *general doings* mere work of routine to keep all right, and beyond that the operations have chiefly been confined to three things; there having been a minimum of labour, as respects cold pits, &c., as the covering put on on Friday remained untouched until Wednesday, except a slight fork-over of the litter on a particularly frosty morning, to break the line of radiation and conduction. On Wednesday morning, there being signs of a heavy fall of rain, the litter at all dry was removed into a shed for further use, as its protecting power depends so much on its dryness, and we are obliged to economise the material.

The first job, then, was wheeling soil and manure where needed, and carting soil to the lawn to place round some of the *Pinus* tribe planted on mounds, so as to give them more feeding ground, having removed the turf before the frost set in. The turf will be replaced as the weather moderates.

VINE-BORDER.

The second job was wheeling out old soil from the back of a vinery, for 6 feet or 7 feet in width, and 2 feet or more in depth, which had once grown *Peaches*, when *Vines* were planted, so as to go over the roof thinly. Since then the *Grapes*, being the most valuable, were allowed to monopolise the roof too much for the *Peaches*; and having been cropped extra heavily, it is the intention to plant *Vines* at the back, so as to relieve those in fruit to a certain extent, and then the front ones may also be gradually renewed. The part of border thus made can be raised a foot higher than before, so that after drainage, a layer of concrete at the bottom, and some 9 inches of rubble covered

with litter and fresh leaves, there will be about 20 inches to 24 inches of fresh soil, which, as it is open and turfy, will sink considerably. The concrete we expect will get so hard that roots will have a job to get through it, even though it be not more than 3 inches or so in thickness. We have several inquiries how to make such concrete in the best manner, and, therefore, some of the minutiae may be acceptable. The great essentials to success, then, are fresh-burned lime, and the reducing that lime by breaking to a fine powder, so that there shall be no little lumps, for each lump will be apt to fly afterwards, and make holes alike for roots and water. We only had a quarter of fresh-burned lime for the purpose, or we would have laid the concrete a little thicker. The space was about 10 feet in length by 7 feet in breadth. The bottom was beaten firm, and then a layer of gravel was placed over it a couple of inches thick, and also beaten down firm and level. With a deeper coating of concrete that would not have been required.

Now to the concrete making. The lime was emptied on the dry floor of a shed and broken with heavy wooden mallets, passed through a fine sieve, and the refuse broken again. Whilst this was going on some rough sandy gravel was sifted through a one-inch sieve, to exclude all the stones that did not pass through. The lime when sifted made four large barrowloads. Each of those had five barrowloads of gravel added to it, and mixed well with spade turning, then water was added to mix it still better into mortar, and as quickly as possible put into a barrow and wheeled to the place, and spread and levelled at once, beating it level with the back of the spade. Then the second barrowload of lime was brought and mixed in a similar manner, and so on with the rest. Where nicety is required, and the necessity of making the most of the lime, much of the success will depend on the thorough mixing and laying the concrete down as quickly as possible; hence one barrowload at a time is better than more. If the gravel has much earthy matter in it, three or four parts will be enough to one of lime. When it is sandy and flinty, five barrowloads may be used. If the sandy matter is soft and red, there should not be so much used. If this were done the concrete will smoke and set quite hard. It is best to err on the side of having plenty of lime. We have known lime used that had been kept long enough to pulverise thoroughly, and thus become mild from exposure. We have also known fresh lime slaked with water to powder it before being mixed with the gravel; but in neither case is the process to be depended on so much as done as above stated—namely, pounding the fresh lime, reducing it in its hot dry state to powder, and giving no water until the powdered lime and the gravel are mixed together.

ICE-STORING.

The third operation was ice-erting. We missed the first chance, because it was inadvisable then to disturb the covers and thus disappoint a shooting-party, and this all the more readily, as we believed we had a stock pretty well for another year. I perceive that our friend Mr. Robson has taken the opposite view from Mr. Beaton, and in their hands I will be content to leave the discussion. Meanwhile I so far agree with Mr. Robson as to the advisability of double walls, with a body of still enclosed air between them. So done, I knew of one house built above the ground that kept ice very well—better than those do generally that are sunk in the ground. The ice-well here was so sunk and built with double walls, I believe; but before I had anything to do with it the inner wall was removed. Now we always find that the ice keeps best above the level of the door-sill, and lower than that it gradually melts all round the sides—no doubt from the heat of the surrounding earth heating the wall, and which I believe a body of air between the two walls would so far prevent. At least, I have proofs that such close double walls above ground alike keep out cold in winter and heat in summer.

Again, without entering on the discussion as to the effects of dry air though warm, and air saturated with moisture though comparatively cool, there can be no question that such muggy air, though cool, will melt the ice very rapidly, and frequently when opening ice-houses a dense fog has come rushing out almost as thick as comes from a washing-house when trays and boiler are in as full operation as the hands and tongues of the washerwomen. Now, if we could get rid of this light air so saturated with moisture, I believe we should just so much prevent the melting of the ice; but whether the ventilation should be continued at the top, or only at intervals, my experience does not enable me to decide. Again, in the ice-tubs

we have, though well closed, the ice always melts round the sides, though protected with wood and cork, good nonconductors though they be. However, not to enter on the matter, I should like our friend, Mr. Robson, to modify the proposed experiment of ice in boxes, not to pierce the sides and tops full of holes, for that would be extreme, but to fill one box within 4 inches of the top, and close then as close as may be; fill another the same, having a small hole on each side near the top, and a small hole in the centre of the lid, and a covering in each case of a two-inch-thick felt nonconductor above the ice, and the option of opening these holes, especially after muggy weather, at pleasure. This would be tantamount to having an air-pipe in the roof of an ice-house, with a small opening in the doorway, and having the surface of the ice covered with a foot of dry straw. For the purpose of ventilation, as I understand the argument, the object is to substitute dry air for moist, but to keep that dry moisture-heated air from acting at once on the ice. But, except for getting rid by some means of this foggy denser air that will accumulate in ice-houses from the sides getting heated, I would join with Mr. Robson in keeping the house as much from the external air in summer as possible.

In addition to Mr. Earley, Mr. Burton, of Hatfield, could give approval to ice-stacks, as that is the only means used there for a large consumption. I know that there the plan answers admirably.—R. F.

TO CORRESPONDENTS.

* * * We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the "Journal of Horticulture, &c.," 162, Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

We cannot reply privately to any communication unless under very special circumstances.

PERMANENT LABELS FOR FRUIT TREES (F. A.).—We find zinc labels, written on with the appropriate ink, as durable, and more legible than any other. They should be attached to the trees by flexible zinc wire, now made for training purposes. If copper wire is used, the galvanic action excited by the contact of the two metals causes rapid corrosion. If the labels have a hole at each end, so that they can be fastened to a branch, the wearing away by friction is avoided, which is very considerable when the labels have freely by the wind.

MICE AND CROCUS BULBS (F. W.).—The only mode we know of protecting Crocus bulbs from mice is by covering them 2 in. high deep, and 4 or more inches wider than the patch or line of bulbs, with finely-sifted coal ashes. As soon as the Crocuses have grown well above the soil the ashes might be removed, for then the bulbs have become unpalatable to the marauders.

PROPAGATING ACHEMILES (J. Green).—The best and easiest way is to depend on the tubers, and grow them separately; this is generally adopted with all kinds. To make the most of new kinds, start the tubers by placing them in sandy peat and loam, with a little leaf-mould, and give them a bottom heat of 80°, and a top heat of from 65° to 70°. As soon as they are 3 inches high, prick 1 inch and a half by cuttings, and then, before May, you may have hundreds of plants—in fact, propagate as you would do a scarce Verbena. Next season you will have so many tubers that you will not need cuttings.

LIFTING ROOTS OF FRUIT TREES (C. J.).—In root-pruning, most likely some large tap roots have been left uncut. Root-pruning does not tell so much on very old, vigorous young trees. In lifting, the best plan is to take care of all the roots; in picking the earth from them carefully; and cutting none if it can be avoided, except such as cannot be traced out from going straight down, which may as well be neatly cut through, as such roots will produce sappy wood instead of fruit-buds. When the tree is thus taken up, level the ground and plant within 6 inches of the surface, and, if not necessary to remove the soil, place some fresh all round the roots, which should be regularly spread out and packed. This will effectually check rampant growth, and if in a few years they get too rampant again, distributing and root-pruning will keep them in order.

ARRANGEMENT OF VINES (J. Constant, *Schönbühel*).—From your list we should select:—For the early-house, 1 Dutch Sweetwater, near the fireplace; 1 White Frontignan; 1 Black Frontignan; 2 Bowed Muscat; 2 Black Hamburgh. For the late-house, 1 Black Hamburgh; 1 Mill Hill Hamburgh; 1 Muscat Hamburgh; 1 Old West's St. Peter's; 2 Lady Downes.

FLOWERING EVERGREENS (J. S. B.).—*Kalmia latifolia*, Double Furze, and *Escallonia nana* are dwarf and will do very well for facing your borders of taller evergreens.

ARTIFICIAL MANURES (E. Talbot).—Write to Mr. Purser, London Manure Company's Office, 116, Fenchurch Street, and ask for a copy of the pamphlet

CONTAINING BOTTOM HEAT (Pontefract).—We can hardly tell you without a cross section. If you take 12 pipes underneath the bed from the present pipes, it would be well to have the pipes in the bed on a lower level. If you have a boiler to be below the level of the bottom of the bed there need be no difficulty; you might take pipes direct from the boiler and return to it, and then have the bed with them as you liked; and an air-pipe at the highest standing point would make all right; that air-pipe with the open end standing higher than the bed. For anything we know, you may take the pipes from those now giving top heat; but bear in mind the water will have an objection to descend, and never should go so low as the boiler. If the boiler is low then, you could take the flow-pipe on an open circuit, and from thence take pipes for bottom heat and top heat on different levels, provided none go below the boiler.

PLANTING BOX-EDGING (B. H.).—From the middle to the end of April is about the best time in the year to remove, divide, and re-plant box-edgings. But we have planned Box extensively for edging during every month in the year.

SOWING LOBELIA SPECIOSA FOR EDGING (Ilem).—Lobelia speciosa seeds sown in March will bloom as early, the same summer, as most of the bedding Geraniums; and Lobelia speciosa is certainly the best of them all for edgings. But last spring there was not a quarter of the seeds which were sold for Lobelia speciosa, probably from the bad seed-harvesting.

DESTRUCTING WIREWORMS AND ANTS (E. C.).—There is no mode of effectually destroying the wireworm but by paring and burning a spit depth of the surface. Ants may be driven away from a box-edging by water, with the ammoniac liquor from the same. At the same time be assured that they do not destroy the Rose-buds. The destroyer of these is some grub or aphid, and it eats are attracted by the extravasated sap.

VARIOUS (W. H. Hipp).—Plant the Raspberry canes in any open part of your garden, and watch it all over the root. A south border could be better employed. For annuals, &c., for your windows, buy our "Window Gardening for the Many"; it would occupy more space than we can spare to give all the directions you need. The seeds you sent are of the common Honesty or Moonwort, Lunaria biennis. Sow them now, they will grow up here, but, being biennial, the plants will not bloom until next summer.

CUTTING TRAINED WALL FRUIT TREES (G. J. R.).—It has been an old and a very bad custom to cut back trained fruit trees soon after they were cut from the nursery and planted. No plan could be so injurious to the trees as all the British nurseries about cutting back maiden or first-year growths of Peaches and other stone fruit trees. The effect of such cutting is only to lay the foundation of disease and death in the tree at the end of the very first season of its growth. Next June after budding is the right time to stop, not cut, all trees which gum—not next winter after a full season's growth is made.

POTTING GLADIOLUSES (Some one whose name is lost).—Now is a very good time to pot a dozen or two of any one of all the sections of Gladioluses. The very end of February would then be the proper time to pot a succeeding crop of kinds, and the first week in March. Sow them now, they will grow up here, but to come into bloom in succession before the same kinds would bloom out of doors from a general planting of them about the middle of April. But Gladioluses is so accommodating that anybody without a square of glass may pot just as many of them as his or her means will allow, as early as the first day of January every year of a lifetime, except when the last of January falls on a Sunday, when the potting must be done on the 2nd of the month, or on the last day of the old year. And it is quite as safe to pot Gladioluses at the beginning of January as at the beginning of the month, for four months. The January-potted ones will then flower first if earlier kinds are not potted in February, March, and April. When Gladioluses are thus potted they like good, rich free soil, not quite so strong but fully as rich as for best pot Geraniums. The soil ought to be neither very wet nor very dry, and the pots ought not to get a single drop of water. All the leaves are full 2 inches long; but then collect the soil in the pots all the leaves are full 2 inches long, and of course, also, that is a bad plan and shows negligence, and the smothering mat then be covered up with something damp; and to boast about them for having been done scientifically in the dark and at such small cost. Lilies—that is, Japan Lilies, to be potted from a lot of 50, remember to the last of February, and the old-established white dwarf Rhododendron Standish's Mont Blanc, crimson or crimson scarlet Blanford, and the blush Rhododendron the Gem, are all three of the very best of their respective colours and at low prices.

NAMES OF PLANTS (A. M. T. Tyne).—1, Polystichum angulare, var. lobatum; 2, Apparently *Lastrea amula*; send a whole front. The top of a frond is most unsatisfactory for identification. No. 1 looks to be a specially well-marked form; but the same remark applies to this also. Names from indistinctly-crown flowers damaged in the transit. You will be more likely to identify them in some neighbouring nursery. No. 3, seems to be *Callitriche*; No. 5, a self-colored bloom of the double-striped; and No. 9, a small flower of *Chandleria*. The others are not in a recognizable state. (P. H. S.).—1, *Thamnopis anastata*; 2, a form of *Frits hastata*; 3, *Davallia dissecta*; 4, *Asplenium fragrans*. (L. Young Subscriber, Teignmouth).—1, *Pilea serpyllifolia*, sometimes called the Bunting Bush. sometimes the Antennary plant; 2, *Francoa sonchifolia*; 3, *Calceola violacea*.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

POULTRY, &c., SHOWS.

January 29th and 30th. ULVERSTON, *Secs.*, Mr. Thos. Robinson and Mr. R. Kitchen, Ulverston. Entries close January 18th.
February 5th and 6th. LIVERPOOL. *Secs.*, J. T. Lawrence, 3, Cook Street. Entries close Jan. 21st.

February 7th and 8th. NANTWICH. *Secs.*, E. H. Rhodes. Entries close Jan. 25th.

March 1st. HALIFAX. *Secs.*, Mr. J. W. Thompson, Southwam, near Halifax.

March 14th and 15th. TAUNTON AND SOMERSET. *Secs.*, Charles Ballance, Esq., Taunton.

June 4th and 5th. BEVERLEY AND EAST RIDING. *Secs.*, Mr. Harry Adams.

CHRISTMAS POULTRY MARKET.

(Continued from page 344.)

THE poultry salesman's difficulties amid this crowd of consignments for Christmas does not end with the Turkeys and Geese; it is the same in fowls, the same in Game. Piles of everything lie in all directions, and although all may be sold to one man, yet every account must be sent separately, and must be a correct one. There is only one clue to the labyrinth—it is that in every package of goods there is a note stating the contents, and whom they are from. This is carefully filed, and any remark necessary to be made is made on the back of it. It will be imagined how clear but how full a man's head must be with a hundred different accounts in it. To perform his duties properly he must be a thorough judge of the value of the stock he has to sell, and to enable him to perform them easily all his customers should be judges of the same. But, alas, for his temper and for the dispatch of business, it has always been the habit to bargain for goods, and while one man, however extensive his dealings, can make his offer, and buy or leave the goods in a moment, another, who is a purchaser of comparatively nothing, gives him no peace. There can be only one salesman, and he is often beset with customers. "How much a penny account?" "A penny a-head more on the fowls." "Give me the price of that row of Turkeys." "Any fresh pheasants?" "Bate me two shillings per head." Such is the life of a salesman during the greater part of the Christmas week. He can get on well with all but the man who offers a penny a-head. He is what is called a close buyer.

It is a work of time for him to lay out a few pounds, and when he is not within 3s. per head to the value he begins at his penny. Such a one is continually snubbed by the salesman, and loses the goods he is trying to buy; but nothing will alter his plan. The next plague to a salesman is the retail buyer, who comes armed with a wife, two children, and a large blue bag. After handling a dozen Geese, he asks the price of one; and on being told by one of the salesman's men, that if he wants to buy a single one he must go to the doctor's shop round the corner, he becomes indignant, insists on seeing the master that he may complain of the rudeness of his people, and when he is civilly told to go along about his business, he does so, muttering something about the "times" and the "public." Leadenhall Market during Christmas time cares for neither. But look at those two men. Both are better dressed than salesmen or poulterers. Both have rings on their fingers. Both are smoking. They are known to the salesman. One is a publican, he wants 100 Geese; the other is a friend of his; he is connected with the club, and as he knows everything, he is, of course, a judge of Geese. They have two things to accomplish; they must please the eye and satisfy the hand. The Geese must be good-looking, and they must be heavy in hand. Now, these are really good customers, buyers of a large quantity and ready-money men; yet they suffer the usual fate of all buyers at Christmas, and cannot ask any great attention. Yet they do not come here to take their chance. They have bespoken their Geese weeks ago, and they know where to go for them. Now, they ask for them, and are directed to the end of the shop, where the shutters are left up to enable packages to be piled against them. The two top-most have each a bunch of white feathers tied to their handles; and they are told if they will open them they will find their Geese. They venture very mildly to ask if they cannot have them brought down, and are told "yes, if they can find a place to put them." At last they are obliged to climb up and begin unpacking; and then it is amusing, for those who have time, to watch the unpacking one by one. Weighing, first by holding up by the neck, then by lifting on a flat hand. Now the cute look that speaks of a lumpy bird, then the shake of the head that tells of a light one; and at last they are bought and taken to a cart.

Then there are men who come to London only once at this time, although they are constant senders. They forward their goods about six days before Christmas, and follow them personally two days afterwards to have a holiday, to see the market, to take "the account and money." Such a man has promised his

wife to be home by the mid-day train, and having money to take, he brings only enough to pay expenses up. At ordinary times the sales-man recognises him, shakes him by the hand, and has the account and money ready, although the goods have been but an hour or two in London. Now, he does not know the market, every place is choked up; lots of people, but all strangers, are moving about. He can hardly find his salesman, all pulling at him and asking him questions. At last he gets a word with his foreman, who tells him he don't think his goods are come. He knows they are; they came by night train three nights ago, and he saw them off. At last he is told to look among the sixty or seventy huge crates, hamper, boxes and barrels, that contain the unpacked goods directed to his salesman. His face is a perfect picture when, at the bottom of the largest and heaviest heap, he finds his hamper, and "he'd just like to know whether Mr. Brown means to sell it, or whether he don't; and if he don't, why he'd just take them to somebody as would, and that's all about it." But there is no such somebody; all are full, and won't be bothered with a stranger's goods. Then the truth gradually breaks on him as it does on other people in different circumstances. Just as he finds the market will go on, and Mr. Brown will have plenty to do without his hamper; so people discover in everyday life that the world is of more importance to them than they are to the world. Captain Marryatt's is a fine code of philosophy. "Take it coolly." "Can't help it, wish I could." "Better luck next time."

"Don't be in a passion," says the salesman.
 "Enough to make any one angry," says the sender.
 "Well, it's no use if you are," says salesman; "it won't unpack nor sell your goods."

"But I want my account and money, and want to go home," says sender.

"It it's only money you want," says salesman, "here's money, and I'll send the account when the goods are sold."

This is a common scene.
 Then comes the retail buyer. He is always a living mistake. A retail buyer has no business at a wholesale stall. A man who goes into a market to buy goods, by the act itself pits his knowledge and judgment as a buyer against those who sell.

SPANISH FOWLS AS EGG-PRODUCERS.

In all the notices I find of Spanish hens they are invariably spoken of as good layers, and yet neither you in your "Poultry-Book for the Many," nor your correspondents, recommend them as good birds to keep for their egg-and-chicken-producing properties. Now, as I have searched in vain to know why, perhaps you will kindly enlighten me on that point.—AMATEUR.

[Spanish hens lay large eggs, and almost daily during the warmer months of the year; but in winter when eggs are most scarce they usually cease from laying, and never average more than two a week during autumn, winter, and early spring. They are tender fowls, and in severe winters are liable to be frost-bitten.]

CAUTION.

I WOULD caution your readers against an individual, by name Ridgway, writing from Gorton, who has shown an anxiety far from praiseworthy to obtain choice birds cheaply. My case was this—In answer to an advertisement in your Journal some three months back, I received an application for some Brahma fowls, requesting they might be sent to the writer's address as above, with a notice previous to their being sent, enclosing "an account," for which the money would be sent by return of post. Nothing doubting, the birds were sent, but no post-office order came; so, after waiting a reasonable time, I wrote to the postmaster of Gorton, and received the prompt though unpleasant intelligence that my correspondent was a man of "no means," and that mine was not the first inquiry as to "who he was." I trust that there were wiser than myself, and their inquiries were made before their birds were sent. Had I done so I should not have had the melancholy satisfaction of writing this letter, and of subscribing myself—R. O.

[This is only one of many victims, not one of whom deserves the slightest pity. Every year have we recorded similar events, and every year have we warned our readers to be wary. There

are two rules which should never be swerved from upon any pretence whatever—1st, Never buy birds which you or some friend has not seen; 2nd, Never part with birds to a stranger before you have received the money for them.]

CRYSTAL PALACE BIRD SHOW.

ANOTHER year of exhibitions has commenced; and among those on the list is one in which all admirers of Nature, and especially of ornithology, take no small interest. The Exhibition referred to is the Crystal Palace annual Show of British and Foreign Birds. There is no place, it may be truly said, better calculated for such a display than the tropical department of that most favoured resort of pleasure-seekers; most of the specimens being fancy birds which have been kept in warm quarters. The beauty of the plants, and the sweet notes of the little feathered songsters, making one forget that the dreary winter is but half passed.

This Exhibition, which commenced on Saturday, will continue open until to-morrow. There were 114 cages of birds, and very few very indifferent specimens among them. The object of most attraction was No. 295, Mr. H. Hanly's Aviary, containing all the British Finches, Linnets, and their rare Hybrids—viz., Hawfinch, Bullfinch, Brambling, Chaffinch, Greenfinch, Goldfinch, Brown Linnet, Twite, Mealy Redpole, Rosy Redpole, Common Redpole, Aberdeverine. Hybrids between Canary and Goldfinch (Jonque), Canary and Goldfinch (Mealy), Canary and Aberdeverine, Canary and Linnet, Canary and Greenfinch, Linnet and Greenfinch, Goldfinch and Greenfinch, Bullfinch and Goldfinch. All Cocks.

The subjects are certainly superior to any previously exhibited, and it is evident that those persons who take an interest in this class of exhibitions have not been idle since the last collection.

The weather this season is, on the whole, more favourable than on the last occasion, both for the birds and for the visitors.

To select any one class for special commendation would be next to an impossibility; but of those which seem to monopolise the greater share of attention, may be mentioned the following:—

Among the British Birds, which, on the whole, were fine in feather, were some very beautiful and novel varieties of the Bullfinch; also two very peculiarly-coloured Magpies, which deservedly obtained a prize. They were the property of Mr. E. Hawkins, of Bear Street, Leicester Square. There were some very fine and beautiful hybrids, particularly between the Goldfinch and Bullfinch. Our favourite Song Thrush and Blackbird had their representatives which were in beautiful condition.

The Foreign Birds were very fine, consisting of some rare and beautiful specimens. Among this class were some very lovely Parrots and Parrotquets from the South Sea Islands, New Holland, and Western Australia, which were very much admired for their elegance and beauty of form.

The show of Canaries was more extensive than on any previous exhibition, and the birds were of a very superior quality; among which may be noticed some extraordinary and beautiful specimens of Mules between the Canary and Linnet, and the Canary and Goldfinch.

The increase in the number of entries is a matter for congratulation to the promoters; and great praise is due to the Secretary, Mr. Houghton, for his indefatigable exertions and attention to, and arrangement of, the specimens exhibited.

The following are the awards:—

CANARIES.

Norwich (Clear Yellow).—First, D. Grace, Bath House, Norwich. Second, T. Madge, Bath House, Norwich. Very Highly Commended, J. Hton, St. Clement's, Oxford. Highly Commended, Mrs. Sathay, Park Terrace, Penze, Cornwall. Commended, J. Judd, Newmarket Road, Surrey; R. Mackley, St. Miles, Norwich. (This class is very superior.)
 Norwich (Clear Buff).—First, E. Hawkins, Leicester Square. Second, T. Madge, Bath House, Norwich. Very Highly Commended, W. Laws, Bath House, Norwich. Highly Commended, J. Hton, Oxford; R. Mackley, Norwich. (Class good.)

Bulzein (Clear Yellow).—First, E. Hawkins, Bear Street, Leicester Square. Second, H. Marshall, Sands House, Darham. Very Highly Commended, E. Hawkins; O. Nicholson, Farnham, Hants. Highly Commended, G. Corbett, Birmingham. Commended, E. Benrose, Derby. Class good. Great improvement on second year.

Belgian (Clear Buff).—First, H. Marshall, Durham. Second, E. Hawkins, Leicester Square. Very Highly Commended, E. Hawkins. Highly Commended, W. Young, Oxford. Comm. only.

Belgian (Variegated or marked Buff).—First and Second, E. Hawkins, Bear Street, Leicester Square. Very Highly Commended, G. Bell, accidentally; G. Corbett, Bath; J. Heath, Birmingham. Highly Commended, H. Marshall, Durham; J. W. Price, Derby. Commended, O. Nicholson, Farnham. (Class very good.)
 Belgian (Variegated or marked Buff).—First, O. Nicholson, Farnham.

Mawseed.—This is the seed of the single white Poppy (*Papaver somniferum*), the plant from which opium is obtained. The seed produces a fine oil, and is found free from the drug. It has a pleasant nutty flavour, and birds are mostly very fond of it. It may be given as a treat, and is far preferable to hemp or rape.

Linsced or Flaxseed (*Linum perenne*), is sometimes given to birds; but they are not fond of it and I think it is not a wholesome food, but might be used medicinally.

Rape seed (*Brassica napus*), a small, round, black seed resembling shot. It belongs to the cabbage tribe and is cultivated for its oil. It is commonly given by fanciers to their birds; but I expect more from a mistaken economy than from any good it is supposed to do them. It is a very hot or pungent seed, and causes inflammation in the bowels, of which many young birds die. I consider it a very unwholesome seed, and only to be used after being scalded and well washed for rearing young Linnets, when mawseed is not easily procured.

Hempseed, the seed of a plant cultivated for its fibre, of which cordage is made. Oil is also extracted from the seed, and in the east an extract is obtained from the leaves resembling opium of an exhilarating nature. The seed has a similar effect on birds, and often proves fatal if continued long. All birds are very fond of it, and it may, if judiciously used, prove beneficial occasionally. These constitute the principal seeds that are in general use for feeding cage-birds.

Before, however, dismissing this subject, I will offer a few words on emendments, by which I mean such substances as are given in addition to seed and clean water. The first of these is sand or grit, which is essential to assist the trituration or grinding of the hard seeds in the gizzard. Lime is also useful and may be given in the form of old mortar, or a piece of cuttle-fish bone, at which the bird will peck when he requires it. Green meat is very good for such birds as will eat it, and may consist of lettuce, chickweed, groundsel, and shepherd's purse.

And, lastly, by way of a treat, or change, they may be regaled on a slice of apple or pear, a nut or almond, a piece of bread or plain cake, or of boiled potatoes, carrot, or broccoli.

When birds are put up to breed they are then offered a more nutritious food which is also easily appropriated to feeding their young. This consists of the crumb of home-baked bread, or stale bun or biscuit crumbled fine, mixed with chopped hard-boiled eggs, and some oily seed. Mawseed I think is best. I have used Gold-of-pleasure seed with great success; but I do not advise the use of either rape or linsced, and hemp should be given only to induce pairing. Perhaps sunflower seeds and nuts or almonds might be added with advantage, but I have not tried them sufficiently to say. There are many seeds of weeds, as thistle, dandelion, plantain, shepherd's purse, &c., which may be given to those that will eat them, and will prove a great treat. A frequent change is always beneficial as well as pleasing to the taste, and while we endeavour to keep our pets in health by judicious feeding, we should also endeavour to please the natural wishes of our prisoners which are completely dependant on us.—**B. P. BRENT.**

(To be continued.)

THE CHEMISTRY OF HONEY, WAX, AND PROPOLIS.

WHENCE come the honey, wax, and propolis found in our hives? Are they in the same state as when gathered by the bees, or have they undergone any change in the stomachs of the bees? In endeavouring to answer these queries we will consider each substance separately.

HONEY, we are of opinion, is nearly if not entirely unaltered by the bee. It is the saccharine secretion of flowers sucked up by the insect, and carried in its stomach promptly, and deposited in the cells of the comb.

The bee has two stomachs. The honey does not proceed beyond the first stomach, and is ejected from it into the cell through the mouth. This was first shown by the anatomical researches of Swammerdam. It receives the fluid collected from the flowers; and Mr. Hunter states, that whatever time the contents of this stomach may be retained he never found them altered, so as to give the idea of digestion having taken place.

This is coincident with the experience of practical bee-keepers, who all agree that it derives a slight flavour from the flowers whence it is collected, and is darker or lighter-coloured in accordance with the plants from whence it is obtained.

Some have argued that the "slight" difference in the flavour

of honey collected from totally different flowers, is a proof that it is altered in the stomach of the bee; for, say they, if you suck the flower of the cowslip and the clover, both are sweet, yet how different the flavour! This, however, is no demonstration at all, for the bee selects the sweetness, extracts the honey from the glands which secrete it, but does not suck the glands which secrete the flower's perfume; but when we suck a flower, we imbibe together the contents of all the glands.*

We are aware Reaumur states that if bees are supplied with sugar, they will from this substance fill their cells with honey, differing in no respect from the common sort, except that its flavour is rather heightened.—(Reaumur's "Memoirs," v. 732.) But, on the other hand, we hear from several bee-keepers that no such change takes place. One eminently practical authority, Mr. Taylor, says, "That the bees have not the ability to change chemically the contents received into their honey-bags is shown by an examination of the saccharine mixtures given to them as artificial food; in which I never could detect any alteration after being stored in their combs." (Taylor's "Bee-keeper's Manual," 175. Sixth Ed.)

That sugar is suitable food for bees is demonstrated by honey being, in fact, nothing more than liquid sugar rendered incapable of crystallising by being mixed with an acid, or, as Dr. Thompson describes it, "Honey is a concentrated solution of grape sugar. When left at rest it gradually separates into two portions, one remaining liquid, and the other becoming solid, assuming the form of small, whitish-coloured spherules. The liquid portion, so far as is known, exactly resembles the liquid sugar from the sugar cane; while the granulated portion is identical with the sugar of grapes." The spherules are formed of minute crystals diverging from a centre. These have been analysed by Dr. Prout, and he found them composed atom for atom the same as sugar obtained from starch. Here are his analyses—

	Starch sugar.	Honey spherules.
Carbon	36.36	35.36
Hydrogen	7.67	7.97
Oxygen	56.57	56.57
	100.00	100.00

As further evidence that honey undergoes but little change in the stomach of the bee, that which is chiefly collected from flowers of the rhodora, such as kalmia, azalea, and rhododendron is said to be poisonous, but certainly is very different from that collected from clover, lime, sycamore, and labiate flowers generally; and that which is gathered from the heaths is darker, and differs in flavour from both those above specified. Then the honey of Surinam and Cayenne, collected by the *Apis amathia* is red; and the honey of Madagascar, stored by the *Apis unicolor*, collected by that insect from the flowers of *Mimosa heterophylla* and *Weinmannia glabra*, is greenish in colour and exquisite in flavour.

It is a fact that sugar cannot crystallise if a little acid is contained in the syrup. For feeding bees, therefore, it would be well to dissolve a small quantity of tartaric acid with the sugar in the water.

WAX is our next subject, and this, as shown by the researches of Huber, Duche, and Hunter, and mentioned long before by apiarists connected with the Lausation Society, is formed from honey digested in the second stomach of the bee, and when secreted in appropriate glands is emitted from under the scales of its abdomen, and, as Mr. Hunter observes, "it is formed beneath each scale of the under side of the belly."—(*Philosoph. Trans.*, 1792, p. 145.)

Huber demonstrated anatomically the glands in which the wax is secreted, and by a series of well-conducted experiments showed that naturally the quantity of wax secreted is in proportion to the quantity of honey consumed, but that an equal, or even larger amount of wax will be formed if the bees are fed on sugar dissolved in water. When fed on pollen and fruits only they did not secrete any wax. The probability of wax being thus formed is evinced by sugar and wax being formed of the same constituents, though in different proportions. Wax is composed of

Carbon	80.14
Hydrogen	14.68
Oxygen	5.78
	100.60

* The opinion that the honey undergoes no change in the stomach of the bee is no modern idea. The Abbé Boissier de Sauvages, a thoroughly practical bee-keeper, published his "Observations sur l'origine du miel," in 1763, in which he says the bees do not make honey, but simply collect it.

To form wax out of sugar, therefore, the digestive and secretory organs of the bees have to separate from it more than 50 per cent. of oxygen; adding 7 per cent. of hydrogen, and 44 per cent. of carbon. Chemists have not hitherto converted sugar into wax, but by mixing it with caustic alkalis and some other re-agents they have rendered it gummy; and it is a fact not without significance, that a peculiar kind of wax, to which the name of cerosine has been given, has been found in the sugar cane.

Propolis is a gummy resin collected by the bees from the buds of trees, as from those of the Tacamallaca poplar (*Populus balsamifera*), birch, fir, &c., and used by them for fastening the hive to the floor-board, and any holes they dislike. Mr. Knight relates an instance of their carrying away an artificial compound of beeswax and turpentine, which he had employed for covering the wounds of trees. Propolis is soft, red, and aromatic.

According to the analysis of Vauquelin ("Memoirs Soc. Agric. Departemen. Seine") it is composed chiefly of resin, a small proportion of wax, and a little acid and aromatic matter. Cadet says the acids are the benzoic and gallic. The resin is composed of

TEMPERATURE OF BEE-HIVES IN WINTER.

In your last publication your correspondent "A DEVONSHIRE BEE-KEEPER," writing on the subject of ventilation of bees in winter, speaks of Huber's experiments as proving that the average temperature of a hive at that season is above 50°. What might be the difference between a warm climate and my own (north of London), where I experimented on five hives, I cannot say; but at foot I give a copy of a thermometrical journal kept some years ago, which may throw a lit le light on the question, as the result is widely different from that of Huber. On this subject I would say a word on the assertion of Nutt, that the heat of a hive, previous to its swarming, may reach 120°, as was the case, he says, with one of his on the 26th June, 1826. Now, it so happens that Nutt's own daily thermometrical journal of that year in June, as given in his book, shows that the temperature therein recorded ranged from 62° on the 1st, to 96° on the 30th, the heat on the 26th June at five P.M. being 91°. Wishing to learn the effect of a certain degree of heat, I suspended a piece of comb and a thermometer in an earthen jar, putting it on a stove. At a few degrees over 100° (I am sorry I cannot give the exact figure), the comb collapsed into a mass of pulp; so that I may be pardoned for a little incredulity as respects the accuracy of both these writers, though I do not mean to assert that a stock-hive in winter never reached to 80°.

My experiments were made, if I recollect aright, with a thermometer inserted into the middle of the hive No. 1, a very healthy one, and I registered the temperature both inside and outside with the hour of the day. I think the hive was ventilated.

HIVE COVERS.

I owe you many thanks for your advice, at page 307, as to "How an I to Protect my Hives?" together with the neat sketches with which it was accompanied.

Of what sort of wood are they formed, and do not you find half-inch stuff so exposed crack and rend in the sun? Are they painted? Or supposing that thick canvass was stretched and tacked on, then painted, would this be a preventive and increase their coolness? Or could you or any subscriber inform me if felt so applied to such light-wooded covers as you describe, proves a durable and desirable addition? and would such be obnoxious to the bees? The front or whole neatly thatched with straw would so far answer the purpose; but then I wish to have them formed so as to afford no shelter to moths, curwigs, &c. You mention you have slate tops for fig. 1. What sort of cover would it make to have it wholly of slate fitted into wooden or iron frames? But perhaps that material might be too hot in summer and cold in winter. Or, maybe, a still better and economical material too, glazed fireclay, now used for many purposes, and of which "A RENFREWSHIRE BEE-KEEPER" told us in one of the early Numbers of your new series his pedestals were formed. In that case I would have them made with moveable tops exactly after the design of your fig. 2. I like that fig. best, the moveable top particularly, for this reason—that supposing I doubled my stocks at any time, I had only to set a second cover on the first (secured), and the top over all to provide for such a contingency. Instead of panels, to improve the plain appearance of the front, I think little pillars halved, one tacked on at each corner, and one each side of doorway, their heads fixed to moveable top, so, if I put two covers together they would only show an extension of the pillar and have less of a doubled appearance, and there being no cross portion as in the panels to catch the descending moisture.

I do not quite understand the entrance and end of landing-board, partly seen in the sketches. Would you explain?

Since I set up as a bee-keeper, of this cover question I have as often said, as did the late Sir Robert Peel of Ireland, "it is my dillylily."—W. J.

[Our hive-covers are made of yellow pine, which, if clear and sound—i.e., free from knots and cracks, will, when well seasoned and painted, stand all weathers without rotting or splitting. They have really proved so efficient that we have never experimented with other substances. The canvass covering suggested by you we believe, therefore, to be unnecessary, and we should fear that the strong smell of ordinary felt might be obnoxious to bees. Slates employed as a roof only are not without their disadvantages, which would be more strongly felt if the entire hive were cased with them. Of glazed fireclay we can say nothing, except that its weight and fragility would probably be against it. Pilasters may be added, but should not be fixed so firmly as to prevent the wood from shrinking or swelling with perfect freedom. The entrance and alighting-board belong to the hive inside the cover; and, not being attached to the latter, should not perhaps have appeared in the engravings. They are, however, most successfully delineated in fig. 2; and, if you will turn to page 12 of Vol. XXV. OF THE COTTAGE GARDENER, you will there find a sketch of a bee-box without its cover, which will probably throw sufficient light on the subject to render it intelligible.]

LIGURIAN OR ALP BEES.

NINETEEN months have now elapsed since I last addressed you, expressing my fears of the success of "A DEVONSHIRE BEE-KEEPER'S" cruise of artificial queen raising, during which time, although I have been a silent, was by no means an uninterested expectant of the snatches of the log with which he so kindly favoured us.

Sympathising in the satisfaction it must have afforded him making good some of the nearer ports, and there safely landing his consignments—anguishing the worst when the large cases containing so many little caskets were thrown overboard, and was, consequently, prepared for the intelligence of the hop-less shipwreck of the adventure announced in your columns of the 19th of November, and now only await the average statement.

Your correspondent, I daresay, never dreamt when introducing his Italian friends into polite Devon society, how they should belie his kindly recommendation by their robbing, at least in one instance, a neighbour of his means, and in how many more the unsuspecting young virgins of their virtue, the unmis-takeable hybrids your correspondent caught sight of on colling satisfactorily establishing their guilt; yet what else could be

looking for when these yellow foreign scoundrels make good a footing in English Society?

"S. B." anticipated the query I intended sending you as to what legal remedy I might have should any neighbour of mine introduce the foreigners into his apiary, thereby contaminating the pure native blood of my favourites; and, notwithstanding the adverse opinion you express, should any be rash enough to make the attempt, it is my intention to crave interdict and try the point; and, although Blackstone did not provide for such a contingency by pointing out the law as distinctly as in the case of strayed swarms quoted in No. 9, still as there are plenty of cases where male animals straying through an insufficiency of the fence among the females of a neighbour, and thereby deteriorating his stock which might be held applicable as a precedent. The only safe fence in this case would be a transport of the obnoxious intruders at least some half-dozen miles from my apiary.

With all I must admit that from reports in your Journal their hardihood and productiveness would seem clearly established, and fair assistants have in addition pronounced them interesting and beautiful too; still, as rank weeds are wonderfully hardy and prolific, and as the yellow wolf-h wasp possesses these qualities in a superior degree, at the same time being altogether wanting, in what S. Amey expressively styles the "main point," I fully reciprocate his and Col. Newman's anxiety for satisfactory information on this head, without which it is not beyond possibility that your excellent Devon contributor, by his dissemination of this variety, be lauded, however unintentionally, in the awkward predicament of that patriotic Scotchman you told us of some time ago, who, in mournful remembrance of his national emblem, sawed the thistle down in his adopted land of Tasmania, the melancholy results of which act were in a short time, as it would be in the case of your correspondent, beyond human power to control.

As it is not unlikely there may be other parties readers of your Journal who, previously to, or simultaneously with, Messrs. Neighbour imported these, and may vie with them as to the credit of being their introducers, it would be highly interesting to all your apianian readers were they politely to afford us some information as to the weight or comparative store collected by, say, a swarm of this and the old variety.

Should their superiority in this respect be as clearly established as their "process" in love and in war, then, and not till then, will I stoop to the "spirit of the age" and procure a Ligurian stock; not, however, without looking back with poignant regret on the many happy years I have spent as—AN OLD FRIEND OF THE BLACK BEE.

INTERBREEDING.

WILL "UPWARDS AND ONWARDS" excuse my pointing out that any diminution in the size of the working bees in a hive is entirely owing to the combs being old, and their cells becoming contracted by long-continued breeding, and is not at all affected by what is usually called breeding in-and-in? As every colony of the species *Apis mellifica* constructs cells of precisely the same size, whether located in this country or at the antipodes, his bees would, therefore, neither increase nor diminish in size if he could succeed in crossing them with "B. & W.'s" Tasmanians. Even *Apis ligustica* builds cells of the same gauge as *mellifica*, whatever M. Hermann may asseverate to the contrary, and for this reason the bees of both species are of the same size, with the exception that I believe *Apis ligustica* to be rather longer than the common bee.

In conclusion, I wish to thank "UPWARDS AND ONWARDS" for the interesting relation of his experience as an Oxfordshire bee-keeper, and would indulge a hope that other apianians may be induced to follow his example in this respect.—A DEVONSHIRE BEE-KEEPER.

SUPER-POSING DIFFICULTY—EFFECTS OF INTERBREEDING.

WITH regard to the super-posing difficulty, in reply to the remarks of "H. B. D." I may state that when I wrote my observations on this subject, I had, unfortunately, mislaid several of the Numbers of THE JOURNAL OF HORTICULTURE; hence the "if," which gives offence. I could only write conditionally; if I wrote "apologetically," it was because of the tone of the

"RENFREWSHIRE BEE-KEEPER'S" remarks, who seemed to deny the possession of eyes and practical knowledge to our respected apianian friend in Devonshire; and, agreeing with one, I wished to be understood that I did not disagree with the other in one of those not uncommon cases, where "both are right and both are wrong."

As to "the principles and practice of storifying not being so well understood in the south" as in the north, that I consider as yet "not proven." But it would be very interesting to your readers if some of our northern friends would kindly detail their method of storifying. The plan I now adopt is extremely simple, and I find it to answer admirably well; but I do not think it materially differs from that practised by Dr. Bevan, who was a veteran in bee experience, and obtained large honey harvests when honey was to be collected. Thus, last year I began the season with only five stocks, from which I obtained over 2 cwt. of honey (run and in the comb); my stocks having increased from five to eight at the end of July.

The bees of Tasmania did, I believe, all spring from one stock—*i.e.*, the stock originally carried out to New South Wales by one Dr. Wilson a great many years ago; and I had personal experience of their excellence in every respect. This one stock became the parent of eleven swarms the first season, which increased to three hundred in three seasons; so a well-known writer on Australia was informed. But I am inclined to think that it is nevertheless desirable, as well as possible, to introduce new blood into an apiary or neighbourhood from time to time, as I have certainly remarked that an increased activity has been the result in cases where I have procured bees from a distance, or removed them to a distance. I say "new blood" advisedly, for I do not think that a mere removal from one locality to another can entirely, or even chiefly, account for this increased activity. Our good friend "A DEVONSHIRE BEE-KEEPER" seems not only to doubt whether the most isolated bees can be protected from crossing (wherein I agree with him), but also whether any benefit is derived from such crossing of blood. This, I fear, must remain open to speculation only; but why should we doubt the beneficial effects of cross-breeding in the case of insects any more than in the case of birds and quadrupeds? and in the case of the Tasmanian bees, which are ever swarming in extraordinary multitudes every year to and from distant localities (as is the case with English bees in a less degree), who shall say that inter-breeding in the fifth or even in the twentieth generation from a common origin (where the bees have been separated by different climates and pasturage for a considerable period), does not keep up at least the vigour and vitality of the race?—B. & W.

BEEES IN CEYLON.

I DO not think the following very brief account of the bees in Ceylon has yet found its way into the pages of THE JOURNAL OF HORTICULTURE. I therefore transcribe it, and beg for it a corner in your apianian department. If "those most productive of honey are destitute of stings," would not our apianian ladies subscribe a purse to introduce them into England?—B. & W.

* *Bees*.—Bos of several species and genera, some divested of stings, and some in size scarcely exceeding a house-fly, deposit their honey in hollow trees or suspend their combs from a branch; and the spoils of their industry form one of the chief resources of the uncivilised Veddals, who collect the wax in their upland forests, to be bartered for arrow-points and clothes in the lowlands.* I have never heard of an instance of persons being attacked by the bees of Ceylon; and hence the natives assert, that those most productive of honey are destitute of stings.—("Ceylon," by Emerson Tennant.)

* A caution connected with the Department of the Surveyor General writes to me that he measured a honey-comb which he found fastened to the overhanging branch of a small tree in the forest near Adam's Peak, and found it one inch of his girth, or about 6 feet in length and a foot in breadth, where it was attached to the branch, but tapering towards the other extremity. "It was a single comb, with a layer of cells on either side, but so weighty that the branch broke by the strain."

OUR LETTER BOX.

DIVIDING FOWL-HOUSE (*Domat*).—Send us a rough outline of the house and its dimensions in writing where the door is, &c.
CANNY CROCODILE IN AFRICAN HIMALAY. *F. L. Lovers*.—The bird is nested with me. First fix a stick of sulphur over the nest, and let a strong wind blow from his cage wash it thoroughly, and disperse the sulphur into all its crevices, perch, &c.

METEOROLOGY OF THE WEER.—At Chiswick, from observations during the last thirty-five years, the average highest and lowest temperatures of these days are 45.4° and 36.6° respectively. The greatest heat, 62°, occurred on the 9th in 1831; and the lowest cold, 4°, on the 9th in 1847. During the period 122 days were fine, and on 116 rain fell.

FLORISTS' FLOWERS,

THEIR DISTINGUISHING CHARACTERISTICS, CULTIVATION, AND VARIETIES.—NO. 1.

THE CINERARIA.

It would be neither just nor generous, in commencing a series of papers like the present, to pass by unnoticed previous workers in the same field; and as I am old enough, and old

florist enough too, to remember almost the first bursting forth into life of the enlarged taste that now exists for florists' flowers, I can call to mind most of those who have by either their skill in hybridising, their liberal encouragement of their growth, or their writings, tended towards this consummation, and I feel bound to say that I know of no one who has so contributed to the present state of things as Mr. George Glenny. He was bold enough when flowers were ragged and starchy, and ill-defined in colour, to fix a standard, which was then considered outrageously high, and impossible, and which, even if reached, it was said, we should be no gainers in, inasmuch as the formality that would be attained would spoil the beauty of the flower. He maintained that he was right, and the event has proved it to be so. His standard is the acknowledged one, and the beauty of those flowers which meet its requirements is recognised not only by the amateur, but by the "outer barbarians," who admire, but know not why. The idea that forced itself on his mind was, that florists' flowers ought to be as circular as possible—the nearer to a perfect circle the better. He was shown such a *Dahlia* as old *Striata formosissima*, and was asked, "Do you ever expect to get such a flower round?" "Yes," was the reply; and now look at the varieties exhibited every year, and say whether it has not been done.

What is a "florists' flower?" is a puzzling question—at least, we all know what they are; but their definition is another matter. A florists' flower cannot be perpetuated by seed, but simply by cuttings, offsets, &c. It is also grown in collections of different varieties. Yet this will hardly define them. The *Erica* is so grown, but it is not recognised as a florists' flower. We must, therefore, content ourselves with saying that they are what they are.

As at this season of the year most greenhouses and conservatories owe a good deal of their gaiety to the *Cineraria*, we have thought it well to begin our notices with it, and now present to our readers a woodcut of what is considered perfection of form in this flower; for it is now a well-understood axiom of florists, that the three properties of any flower arranged in their relative

order of merit, are—1, form; 2, colour; 3, size. Antecedent to all these is the habit of the plant; nothing compensating for faultiness in this respect (more of this anon). In looking at the pips of the flower as given, it will be perceived that they are evenly circular, that the petals are closely laid, so as not to leave any gaps between them, which would be fatal to its symmetry, and that they are gently curved so as not to run in straight line from the disk, but with a slight wave, which greatly adds to their beauty. The edges of the petals, too, are free from any notch in the centre—a defect which some flowers possess in a great degree. The petals ought also to be about twelve in number; a larger number confuses the pip, a smaller one makes it too open. These may seem very arbitrary rules, and so they doubtless are, but every thing connected with a taste of this sort is arbitrary. Then, as to Colour. Where the flowers are edged, the colour ought to be confined to the margin in either broad or narrow bands; there being two types of edged flowers, in one the white having a much larger proportion to the flower than in the other, and in these cases the flower itself is generally larger altogether. In a self-coloured flower it ought to be bright and clear, muddiness entirely taking off from its beauty. Size is, as I have said, subordinate to the other two properties; but a really under-sized flower must now be discarded; for in all the colours in which the *Cineraria* appears, there are varieties sufficiently large to satisfy the demands of the amateur, and a large-sized flower is unquestionably more striking than a small one.

I have said that habit is of the first importance. Of what use is a flower, however beautiful, if it be "miffy," difficult to propagate, or ugly when grown? Take, for example, *Slough Rival*, a pretty flower enough, but then the foot-stalks are so wiry, and the pips so much apart, that one never gets a good head of bloom. On the other hand, look at *Miss Eyles*, which obtained a first-class certificate last year (figured in the current Number of "Floral Magazine"), and you see at once the vast superiority of its habit. The pips are kept close together, the plant is dwarf, and, consequently, it keeps an excellent head of bloom. The potted figure represents one which was photographed from life, of *Ayres' Cœrulea compacta*, but I know not what amount of training it had; but it is an admirable specimen of what a *Cineraria* ought to be, and when it can be reached with little trussing, the value of the variety is greatly enhanced.

The culture of the *Cineraria* has been oftentimes dwelt upon in the columns of THE JOURNAL OF HORTICULTURE, and it may be, perhaps, superfluous to say much upon the subject, but there are a few points to be carefully attended to. The compost must be open and rich; and from the time the cutting is rooted, the plant ought never to be allowed to stand still; the pots enlarged until it gets into the blooming one, and kept moderately well watered, and just clear of frost, so that before the bloom-buds start up they may have fine, large, broad leaves, and the pots be well filled with roots. As the bloom-buds advance, guano water or other liquid manure may be

applied; and, above all things, green fly must be carefully looked after, and frequent fumigation given. I may be a bungler and not have known how to use these new substitutes for tobacco, but I have to say to aphid pastils, tobacco-paper, &c., "*Este procul, profani!*" and I quite agree with a recent writer in your periodical, that it is better to give a fumigating two successive nights than a very severe one on one night only. Those that are not killed by the first attack are generally very sick, and a second one generally settles the matter with them before they have time to recover. When the plants have done

blooming they should be cut down and turned out of doors in a shady place, so that they may begin to throw up the offsets on which the stock for the following year depends. These must be taken off as they reach a fair size, potted in nice open sandy compost, and placed, if possible, in gentle heat just to start them. The earlier this is done the earlier the plants will come into bloom, and a little practice will very soon determine what is the best time to commence operations. Some want them for decoration, others for exhibition, others for their own pleasure, and they must regulate accordingly.

Diagram of a perfect Cineraria.

Cineraria, showing a desirable habit of growth.

As to sorts, I have, through the kindness of my excellent friend, Mr. Charles Turner of Slough, had the opportunity for some years of seeing and growing the new varieties as sent out; and from my own experience submit a list of those which seem to me to approach nearer to the standard I have laid down than any other. I take first the class of

SEMI-S.

Adam Bude, a lovely rose. Of dwarf habit and very free blooming.

Brilliant (Smith), rich crimson. A very effective and useful flower.

Captain Schneider, bright light blue. Very excellent.

Duke of Cambridge, brilliant crimson. Dwarfier habit, and brighter than Brilliant.

Reynolds Hole, large, crimson. Very stout and free-blooming.

WHITE EDGED WITH ROSE, CRIMSON, &c.

Constancy, purplish-lake edging.

Flower of Spring, rosy purple edge, disk dark.

Incomparable, crimson carmine edging. Excellent habit.

Maid of Astolat, carmine purple edge. Strong and vigorous habit.

Miss Marnock, rosy lake edges. Free bloomer.

Miss Eyles, rose, dwarf habit. An excellent variety.

Perfection, rosy carmine, light edge. Excellent shape and good habit.

WHITE EDGED WITH BLUE, PURPLE, &c.

Bellissima, azure blue edges. Fine shape.

Eclat, dark shaded purple edges.

Lady Seymour, deep blue edge, dark disk.

Prince of Wales, deep blue edge and dark blue disk.

Royal Marine, light azure blue.

The Colleen Bawn, blue-edged and blue disk. Showy.

—D., Deal.

PRESERVING ICE.

I AM so much pleased with the effects of "raising the wind" in the matter of ice-preserving, that I must adjust the girths of the saddle, lest the next runner should have an awkward tumble by the way. The saddle has been on the right horse all this time, however, and the fix is most amusing, for there is not a syllable of difference among all our differings about keeping ice when

rightly explained. It is just such another fix as that about the variegation of plants. We are all agreed about the variegation as to what it is, we differ only in the meaning of the terms made use of in the explanation of what it is; and it is just so about the ice. We all agree, but in different degrees of belief, that damp is the greatest enemy to ice, and that heat is the next greatest; but here extremes meet as in a circle. The degrees of belief in the effects of damp air on ice range from absolute certainty to the faintest idea that heat itself may be the more active agent; and so it is, and without it there would be no damp to destroy ice.

The misunderstanding about ventilation is still more easily explained. The greatest gardener of us all, Mr. Thomson, of the Archerfield Gardens in the Lothians, has the greatest amount of ventilation all round his ice-heaps of any of us, and yet he is, or seems to be, the lesser advocate of ventilation. But his most excellent hit in keeping ice in pits made in loose sandy banks, explains the whole theory of ventilation from first to last. He uses more ventilation in those pits than ever I contemplated since I had adopted that practice. Loose sand is as full of air as a sponge is with water after you dip it in the basin, and the melting from the ice runs into the sand as fast as it comes, and then there can be no vapour, nor need of the air in a current, for there the ice is in as close a contact with a large body of air as with a large body of sand.

Now, when I ventilated the first ice-house, and when I advised an old ice-house to be ventilated, I could not get the air one-tenth so near to the body of ice as Mr. Thomson has it. The current was, and must have been, far away from the body of the ice, as those who know the arrangements about these old ice-houses well know. The ventilation could only take along in the current the vapour after it rose from the sides of the ice deep down in the ice-well to the level of the side door into the well. The current was constant day and night, but not one particle of the air in that current came, or could come, in contact with one particle of the ice; and whether that current was at 30° or at 90°, it could not make the smallest appreciable difference to the ice farther than that the warmer degree sucked in the vapour over the ice with ten times more greediness. Then the warmest must have been the best degree for saving the ice, so to put it; but the way it acted was second-hand, as it were—it prevented the vapour from rising to the roof where formerly it caused a constant drip to fall down on the ice, which dripp and which vapour was, and is yet, the great fault of the old ice-house.

I must confess to having baited my book for salmon fresh from the mountain stream when I spoke of the ventilation through the air-drain, and I consider I was most fortunate in getting such so many pounders as Mr. Robson and Mr. Thomson. I said, and there you may see and read it, that I would not have an air-trap in next the ice, but out next the open air. I had some faint hopes that some would take that as part of the system of ventilation day and night through the upper passage, and my good luck soon brought my hopes to pass. Then, if you will show by any word or sentence I ever wrote about ventilating an ice-house that I contemplated, or advised, one more degree of heat to reach the ice that way than the rest of us, there shall be a difference between us, but not till then. A strong gale passing constantly through a ventilated ice-house, as I recommend it, even in the dog days, could no more reach the ice, or impart cold or warmth to it, than if it were a dead lull all the time; and my air-trap at the open-air end of the lower drain was to be worked as I thought best, which was the way I put my bait on to raise the wind and to have a chat and chirrup about the ice question.

When I am outside of a house or place which I want to be warmer or cooler, and I have the power of the ventilation in my own hands as in the air-trap at the outer end of the waste-drain, I would no more admit a particle of air that way on a foggy day, or on a hot sunny day, than either of my fellow labourers would; and there is not a pin's difference between us in all that relates to ventilating ice, or, which is the right and proper way of expressing it, in all that relates to the keeping off or clearing away damp air from the sides and roof of an ice-house.

But Mr. Robson and Mr. Thomson are both right and both wrong about the effects of heat on ice, and the effects of strong currents of hot air playing constantly over it—quite wrong, and their views are upset every year of our lives in their native land by the hand of Nature, and no one can gainsay it. Both of

them also gave examples of ice-houses which would not keep ice anyhow—an easy thing from any county in the kingdom, and both blame the wet for the melting; and if I should go and get rid of that wet by a strong current of air between the source of wet and the ice without affecting the ice itself, they both would blow at me with the garden-engine till I had enough of it, and when I had I would just tell them how near we all of us were to the mark without knowing it.

There is an old plan and a very good one, however, which would cure such ice-houses as run to waste from damp in the soil next to them, and that remedy is exactly the same in principle as mine for drying off stagnant vapour. There are a figure of it and the description in one of the early volumes of the "Gardener's Magazine." The plan is to work up outside the walls of an ice-house a puddle of clay 1 foot to 18 inches wide all round and over the top. That would be easier and less expensive than double walls, although nothing is so good a nonconductor for us gardeners as a column of confined air; but the difficulty of keeping the air dry between the very best Middlesex stock bricks is just as great as that of keeping ice from melting, as I can show from my own experience with hollow walls. I once had a range of cold pits with hollow-brick walls, which were before my time used for Melons and Cucumbers, and the linings for the Melons and Cucumbers were found to do as was intended; but when I used them for cold pits were not so easily kept warm as the solid walls of other pits, and I had them altered, and in doing that I found the tide-marks of the damp air between the walls sure enough, and the pits were more easily kept warm after the alteration to solid walls. Ever since I have been jealous of letting damp linings be used against hollow walls for cold pits, but linings of dry stubble from the corn fields to hollow walls is one of the best means of making cold pits hold out against cold and damp.

One of the most convincing proofs I can give to show that there is not a shade of difference between my ideas of keeping ice and those expressed by Mr. Thomson is this: The last ice-house in which I could not keep ice till I had it ventilated, was made in a sand-bank exactly like the sand-bank in which he finds the ice to hold so well and so long. In one part of the bank we had pure white sand, as good for ordinary propagation as the Reigate sand; but where the ice-house stood the sand was not so purely white. I used to say at a venture, and I said it to scores of people as well as to the owner, that if, in the first instance, they had made the opening in the bank and had not bricked it up, the ice would keep better facing the sand than against the bricks, because the sand would suck the moisture as fast as it flowed, whereas the bricks confined it, and thus caused the air next to the ice to be in constant vapour. But I was not so confident of the fact as I am now after hearing the proof-of-the-pudding way from Mr. Thomson. The fact itself, however, is worth all the pains and penalties which are likely to result from what might be taken as opposite views of so simple a thing as keeping ice; and if I should ever be able to go and eat Strawberries and ice cream either at Linton or at Archerfield, I shall relish it all the better in recounting the facts in this tournament; and I do hereby take blame to my own self for not having more clearly defined my meaning about the rays of the sun in a breeze, when telling of how I had seen them preserve the ice in a state of nature. But, after all, if I had done so the thing might not have turned out one-half so well as it is.

Nothing is more dreary than to write week after week, and month after month, and then find after all that every word had been taken as a matter of course about which there could be no two opinions; and I never disguised the fact that I oft and often baited my hook for a "rise" of discussion, if only to see if people took interest or not on what was the subject matter of my tale. It has not been often my lot to get so good a "rise" in such dull weather as this one or two; and the half rise from Mr. Fish, who seemed last week to hesitate between a "rise" and a swallow on the doctrine of taking dog-day heat in contact with stored ice in the breezes of the air, which no one ever dreamed of, save those who mistook my Ben Nevis tale of ice never stored for use. All that we unitedly insist on for the preservation of ice may be quoted from the last article I wrote on the subject at page 349. "Keep damp as much as is possible from ice, and you have done all that can be accomplished on that law, or side of the question. Keep it also as much from heat as is possible, and then there is no more possibility of assisting the keeping of ice." I wrote that on purpose to put Mr. Robson and myself on the same footing,

because I had seen that he misunderstood me in the matter of exposed ice and snow to open-air influences; and, as is right if should, it will also put Mr. Thomson and his humble servant in the self-same boat. I am exactly of the same opinion as Mr. Robson is about the cause of waste in ice; but I am not puzzled as he is about how the cause takes effect—that I will kneed from the beginning. I am also exactly of the same opinion as Mr. Thomson is about the cause of waste and the cure of it, and I am wiser now from hearing his peculiar way of cure in the deep hollow of a loose sandy bank.

If ever the subject is again before us, let it be distinctly understood that no one can alter the degree of heat or cold in an old-fashioned ice-house by ventilating it through the side passages, and through the usual side door to the well, and up and out at the centre of the dome. I never could alter the temperature of that house one single degree, and I had four thermometers in four different parts of the house and passage for full five years. I said it was made more a game-borler than anything else. I also made it an experimental fruit-room, and I took Peaches out of it in April along with pheasants, as fresh as the Peaches were in September, and the pheasants on the last lawful shooting-days. I attended to the whole personally, and I assert that no one can increase or diminish the degree of heat round the ice in the middle of July or August by the strongest current of air that can be got through the usual passages. I recollect very well being surprised when I made the discovery; but the reason is, that warm air will not descend among cooler air if it can pass off upwards. The ice is much below the bottom of the side door to the ice-well by the time people begin to draw out ice, and it had been always a point with me to advise people to have a foot thick of straw over the top of the ice, which was always dry, and no straw at all facing the sides of the ice which was as constantly damp, or nearly so, under those conditions. How the idea of conveying heat to the ice by a sharp current far above it came to enter the brains of such sensible and so practical observers as my worthy friends, is just as I have surmised above, and it was from an entire misconception of my meaning altogether. Yet, as many might be led by the same route, it is much better as it is to the public, and none of us will ever be the worse for our part of the story. D. BEATON.

A FEW DAYS IN IRELAND.—No. 12.

(Continued from page 339.)

GLASNEVIN CEMETERY AND BOTANIC GARDEN.

GLASNEVIN is distant two miles from Sackville Street, and is as much connected with Dublin on the north as Kensington is with London on the west side. The chief attractions to strangers at present are the well-kept cemetery and the still more beautiful and excellently managed botanic gardens.

We twice passed the cemetery—once late in the afternoon, and again rather early in the morning; and even in the latter time there were not wanting those who were showing their respect for the departed by mourning over their dust, and tending plants, and scattering flowers over their graves. Such an employment can hardly fail to soften and elevate the feelings of the living. In this hard utilitarian age everything should be encouraged that tends to keep a tender, evergreen spot in our hearts ever awake and sensitive to the throbbings of human sympathy. The man is worthy of being alike pitied and condemned who could come from such an employment at the grave of a friend, and then go and commit an act of injustice or of wrong.

The neatness of this cemetery would give a useful lesson to many managers of graveyards in England and Scotland. What would our Irish friends think of us if in one case they saw the sacred spot pastured with sheep, and in another found nothing in the way of flowers but Nettles so rank and luxuriant that finding any particular grave was next to impossible? No doubt this is more in consonance with some minds than the trimmest neatness and the brightest flower, as being more in unison with the desolation of heart which they feel. Great changes have been and are taking place in this respect for the better on this side of the water. Might not such feelings of sorrow and the extreme of desolation be lessened, if the surroundings reminded survivors that those they mourn had "not been lost but gone before" to bloom as perennial flowers in a region more bright

and serene than ours, where the atmosphere is ever pure and never disease nor death-laden? The sigh heaved and the tear shed, whilst the homely flowers are scattered on the lowly grave, may be more relieving and heart-bettering than merely looking at a costly memorial or monumental urn, which only the comparatively rich could erect as a sign of their respect and a proof of their sorrow. Monuments, some simple and others costly, there are here in plenty; but the tower erected to the memory of O'Connell rises high above all others, and forms as conspicuous an object from a distance as the column erected to the memory of Nelson in Sackville Street. This column, or tower, as a memorial of Daniel O'Connell is more massive than beautiful in its proportions, is 160 feet in height, built of whitish granite resting on an octagon of limestone, and surmounted by a cross at the summit. How short the time since the name of O'Connell was on every lip! It did surprise us to find a sort of general reluctance to speak of his deeds. Men have lived whose renown will outlive all monuments. Costly monuments, perishing though they be, will long survive the memory of many they were designed to commemorate. Fame at best is but short-lived. The only heroism and greatness that will survive in the hearts of a people are those identified with goodness.

BOTANIC GARDEN.

Some ten minutes walk will take us from the plants of the cemetery to those of the botanic garden. This beautiful demesne of some thirty acres is the property of the Royal Dublin Society, and is partly maintained by a regular annual grant from Government and an extra grant at times for particular purposes. The garden furnishes specimens for the lectures of the Royal Society and several other scientific bodies. The public is admitted free to the lectures at the garden. Free admission is also given to the public on Mondays, Wednesdays, and Fridays, from twelve to six; and on Saturdays from two to six; and since August, also on the Sunday afternoons during the summer. On Tuesdays and Thursdays visitors are admitted on payment of 6d. for grown-up people, and 3d. for children.

We can well understand how the gardens should be crowded on fine days, not only on account of its natural beauties, the great interest of its contents, and the high keeping and neatness everywhere perceptible, but also for its many classical and legendary associations. The ground was originally held by the poet Tickell, and here he composed the ballad of "Colin and Lucy." Here he enjoyed the society of Addison, who came to Ireland as Secretary to Lord Sunderland. Amid all the changes in the garden, the favourite walk of Addison has still been preserved with no great alterations. The neighbourhood is also distinguished for the residence of Swift, Parnell the author of the "Hermit," and Brinsley Sheridan, &c. The river Tolka, which bounds the grounds and runs through the village, has been the scene of many a fight and foray, even as far back as the times when the Danes tried to establish themselves in Ireland. From that rivulet the fountain in the flower garden, and all the houses, &c., are supplied with water by means of a water-ram—the first instance when it was accomplished of such a mode being employed in Ireland.

From the obtaining of the ground of the Royal Dublin Society about 1736, and the commencing of operations in earnest, the gardens have been steadily increasing in influence and fame. Mr. Underwood, the first Curator, held the appointment for thirty-six years; and, on his superannuation Mr. Niven was appointed in 1834, and at once commenced many alterations and improvements; and, on his resignation, the same active energy to make the garden worthy of the title "Royal" has been continued since 1838, by the present much-respected Curator, Mr. Moore; so that nothing but greater means are wanted to make this garden second to none of its kind in Europe. The old houses have been mostly removed, and a fine iron curvilinear range substituted at a cost of £5000, built chiefly by Mr. Turner of Dublin; and, on the 13th of September, other houses were undergoing a widening and a repairing process.

We very much regret that we must give a mere outline of this beautiful garden instead of anything worthy of the name of a description. We arrived at it too tired and too late in the evening thoroughly to investigate its beauties; and what added to our disappointment, Mr. Moore, whom we were anxious to see, was from home, and in his absence we felt that the beauties of Glasnevin were something like Shakspeare's "Hamlet" with the

part of Hamlet left out. We fairly counted on half a day at another time; but, owing to the contrariety of railway companies, we were left kicking our heels at a distant station, and reached Dublin only in time for the steamer, instead of at home as we expected—in fact, but for the inquiries about Glanerin we would have put off the whole matter until another and more fortunate visit.

At the entrance on the S.E. side are very handsome gates, and a nice lodge and a broad piece of gravel in front, with a museum on one side and a lecture-room on the other. North from this gravel is the Curator's house, with a lawn in front. From this broad space of gravel three main walks diverge—one westward through part of the arboretum, rosey, specimen-reserve garden, and bending southwards to the horticultural grounds. The second leads northward, past the lawn in front of the Curator's house to part of the flower gardens, and onwards to the main range of houses; or bending westward, you may go through the flower garden and the various arrangements of herbaceous plants until, joining the arboretum on the west, you may turn north to the aquarium. The third walk leads north-eastward, leaving a space of lawn between it and the Curator's house on one side and the boundary on the other, and terminating opposite a lofty octagon house, which may be considered the commencement of the main range of houses. By the sides of this walk are some nice specimens of *Araucaria imbricata*, *Cryptomeria japonica*, *Taxodium*, &c.

The lofty octagon house was originally intended for a fine plant of *Araucaria excelsa*, and now it contains a fine young thriving plant of that species, and others too tender to thrive out of doors, as *Araucaria Cunninghamii*, and *braziliensis*, &c.; *Cuninghamia sinensis*, *Donkeya australis*, some singular-foliaged Australian plants, and a few others of massive foliage, as *Chamaecyparis humilis*. Close to this octagon house is the Victoria regia house with that noble plant in the centre, and *Nymphaeas* and *Nelumbiums* at the corners, with many other interesting plants, not the least attractive of which is the *Vallisneria spiralis*, which, when placed under the microscope, shows the sap moving in the interior of the plant.

We now enter upon the main range of curvilinear houses, the first wing of which is 150 feet long, two-thirds of which are devoted to New Holland plants—as *Proteas*, *Banksias*, *Dryandras*, *Acacias*, and *Pea-blooming-like* plants without number. A great part of the front shelf of this house was filled with succulents—as *Mesembryanthemums*, *Crassulas*, &c., enough to make an enthusiast commence longing. What a fine display such plants would make hanging over rocks on a sunny day! For many amateurs in towns, and who must be at their offices all day, we know of no tribe of plants more interesting for variety of form, and also for beauty of flower; and if frost be merely excluded, no plants require less attention or trouble, as, except for a short time in summer, they can pretty well water themselves if the air is not extra dry. The rest of this wing is devoted to Cape Heaths and their hybrids. *Hardenbergias*, *Keudnyas*, &c., are grown as creepers; but the most conspicuous object in this way was a fine plant of *Bignonia Cherere*, which generally blooms most profusely.

The central house is 40 feet in height, and is devoted to Palms and other fine-foliaged plants of that group. Some of the most conspicuous were *Sabal Blackburniana*, *Lantana borbonica*, *Phoenix dactylifera*, *Caryota urens*, *Cocos nucifera*, *Musa* of kinds, *Pines*, *Dragon trees*, *Bamboos*, &c.

The next wing of the range is divided into two parts, the first a Cactus or succulent-house, and the second a stove for tender exotics. In union with the larger kinds of *Cereus*, *Epiphyllum*, &c., are a fine lot of *Mammillaria*, *Echinocactus*, *Melocactus*, *Stapelia*, *Aloes*, *Haworthias*, &c. These are just as well worth the attention of the lovers of the singular and grotesque in form as the succulents already mentioned; and, provided plenty of heat can be given in summer, and a temperature averaging from 48° to 52° in winter, and kept rather dry then, they are so careless of attention that if neglected for some days they will scarcely ever feel it, or upbraid you for it by any languishing looks. No plants will better repay the little attention that is given them, and as a good number of the smaller ones can be held in a little space, there would always be something fresh. We have seen some windows very interesting with *Mesembryanthemums* alone. These small *Cacti* would require more heat; but the whole tribe of *Cereus* and *Epiphyllum* will do well in windows, except the night-dropping kind of the first; the great points being growth in the early part of summer, as much sun and as little

water as possible in autumn, and as dry in winter as just to prevent shrivelling. We hope, after all this, the windows in Dublin will have something green, at least in summer.

The next part of the wing is devoted to a nice collection of stove plants, embracing *Cinnamon*, *Pepper*, *Arrowroot*, *Ginger*, *Banyan tree*, *Coffee plant*, *Sugar-cane*, the *Egyptian Papyrus*, and a fine plant of the *Astrapei Wallichii* from Madagascar.

In a line with these houses, and surrounded by a hedge, is a pit-and-frame ground; and turning from the southward through the flower-beds we reach another range of houses—the first a *Feru* and *Orchid-house*, 100 feet long and 20 feet in width, divided into two or three compartments. Here, in addition to fine *Orchids*, *Venus's Flytraps*, *Madagascar Lace Plants*, *Pitcher Plants*, *Sarracenias*, the *Ferns* of themselves would give work to an enthusiast for a day; there seemed to be no end to their numbers, their varieties, and their beauty. We observed that *Pteris argyrea* and other newish kinds were springing up all over the place in hundreds. The other parts of the range are devoted to showy plants of trees *Rhododendrons*, *Camellias*, *Azaleas*, *Tea plants*, *Dacrydiums*, &c.

A small rockery and aquarium is placed in front of this range; and the rest of the pleasure-ground and flower garden joined on south and west sides by the general herbaceous grounds, hardy British plants, and hardy medicinal plants. The flower-beds were partly grouped and partly mixed. We should like to see the herbaceous arrangements at any time, but more especially in May, June, and July. The chief things we had time to notice about them were the excellence of the arrangement, enabling the visitor to look at each plant so conveniently; and then the large massive size of each specimen generally. If herbaceous plants come to be run after, as we prophesy they will, we fear Mr. Moore will have plenty of tantalising longing visitors.

We were not able to see the interesting large aquarium or the horticultural department, and only part of the arboretum, which is scientifically arranged; but we saw enough to be delighted with the arrangement of the grounds, and the easy sweeps of the walks in excellent order, which enabled the visitor to see all the finest specimens without going off the gravel, and yet one walk hardly ever seen from another, unless near the points of junction. We noticed near the houses a fine specimen of the *Weeping Willow*, the *Chinese Paper-plant*, and fine plants of *Pampas Grass*, which was first raised here, and distributed to British and other gardens. To mention interesting specimens would require a list like a catalogue.

Owing to the calcareous subsoil *Rhododendrons* do not flourish without prepared soil; but the *Fir* tribes, *Cypresses*, *Arbor Vitae*, and *Junipers* seemed to be at home. Such young *Cypresses* as *Nordmanniana*, &c., were becoming fine plants. A young plant of *Picea nobilis* was full 20 feet in height, and not to speak of leaders, &c. There are two splendid plants of *Pinus Pallasiana*, which must be pretty well 60 feet in height, and which have been planted about sixty-five years. The whole of the hardy tree and shrub department is not only interesting to the botanical student and most instructive to the young gardener, but of great importance to visitors possessed of grounds, as here they can form a good idea of what will suit them, whether their demesne be a single rood or a thousand acres.

The whole of the departments, even those where horticultural cropping and experiments are conducted, are essential to carry out the design contemplated—alike a botanic garden and a suitable manufactory for rearing and sending out over the country intelligent young gardeners. From a most interesting popular hand-book of the gardens, prepared by Mr. Moore, I learned that the young men employed were chiefly of two classes. First, those who had already studied several years in good gardens and came to be farther accomplished in practical botany and general gardening. These are admitted for two years, and are employed one year in the houses and one year in the grounds. These are lodged in the gardens so as to be under complete supervision. The other class are regular apprentices, who are also lodged in the gardens, have access to a good library, &c. These latter to be gentlemen's gardeners, we presume, will travel to some good gardens and be employed there to learn what is wanted in well-regulated private establishments. It was supposed that a third class might be formed—viz., one that would give their labour without wages in exchange for the instruction received. But as yet none have entered that class; and until a higher remuneration is given to intelligent and scientific as well as practical gardeners, there is little chance of such a class ever becoming

numerous. So long as men can be found combining a fair knowledge of flowers and practical gardening, with many of the acquirements of the artist, the architect, the landscape gardener, and the philosopher, and making all these contribute to the comfort and the satisfaction of their employers, and then besides the knowledge that their services are valued and so far appreciated, receiving in remuneration little more than a bricklayer's labourer in London—men of intelligence and push will think twice before they thus sacrifice, as it were, a year or two of their lives, and ask if it would not be better to take their industry and knowledge to a better-paying market.

The opening of these gardens on the Sabbath has been a new feature this season. Some of our legislators agitated the subject in Parliament last session, and as much as stated that unless the gardens were so open to the public they would oppose the usual grant being given. Whatever objections might exist to such opening, the opportunity was embraced by the people. We find in the *Times* of the 9th of December an extract from a report furnished by Mr. Moore to the Council of the Royal Society of Dublin, that from the opening of the Gardens on the 18th of August, for twelve Sundays in all, there had been 78,132 visitors, and that the highest number on a single day was on the 6th of October, when there were 15,000 persons. He testifies "that the results are of a very satisfactory character, the people conducted themselves in the most orderly and decorous manner. Owing to the narrowness of the passages in the hothouses some pots were knocked down, and some valuable plants injured; but this was unavoidable from the thronging on some occasions. In connection with the conduct of the people, it may be mentioned that not a single case of delinquency was brought before the magistrates by the police."

It is most gratifying to find from such a report that our Irish friends, when their honour is appealed to, are quite as trustworthy as their English brethren. From anything that appears to the contrary, the managers seem to be in favour of such openings on the Sunday. Certainly, if any places, except those for religious worship, are open at all, it should be such paradises, addressing us from every aspect by the beautiful in nature and art to stun and avoid degrading and debasing pleasures.

We found, however, at several places that this opening on the Sabbath was not looked upon with unmixed satisfaction. One argument used was that it deprived so many men for the whole day from obtaining the religious privileges of public worship. I am not aware how far this could be met in such a neighbourhood as that of Dublin. Some people even advocate the opening of private gardens on a part of the Sunday: such a thing if at all general would soon become intolerable; there would be no Sabbath of rest for the gardener. In some places there is little rest as it is, as we believe merely from want of consideration, some employers make it the chief day for seeing their gardeners. When half-holidays shall become more general, any claims for such openings will lose much of their force. The public with its acknowledged rights and power should use its spiriting gently, so that the greatest amount of pleasure and advantage may be obtained at the smallest amount of inroad upon the rights and consciences of others. We have no doubt the gentlemen mean well in general who advocate the opening of museums, gardens, &c., on Sunday as a means of educating and elevating us of the working classes; the difficulty would be to find in common justice a stopping-place. We fear that in some cases the "elevation of the masses" is merely the cloak for getting money out of them. There can at any rate be no harm in testing the sincerity of such benevolence by insisting—if such openings there are to be, there shall be no moneytakers, but all shall be free.

R. FISH.

REGULATING NEGLECTED WALL FRUIT TREES.

I HAVE just entered upon a villa with a garden, surrounded by a low wall about 8 feet high. This wall is pretty well stocked with trees—Apricot, Peach, Nectarine, and Plum; but all trained, or rather untrained, after the following fashion: Two or three main stems running up to the top of the wall, thick and bare; a few small branches extending from them fan-shape, but at the top a whole thicket of wood, which the pruner has cut straight off just above the top of the wall. Now I have cut out some of the thick bare wood near the top, and brought the trees below the top of the wall, but they still seem so impracticable that I do not know what next to do with them.

What shape am I to try to bring them into, fan-shape or horizontal?—F.

[We fear from your account that the Peach and Nectarine trees which have been growing against a low wall and merely cropped off at the top of it like a clipped hedge, can never be made nice, fruitful, and shapely trees. The Apricots and Plum trees may perhaps submit with more grace to the pruning-knife and skilful trainer. It would, therefore, perhaps be better to destroy a part if not the whole of the Peach and Nectarine trees, and plant young ones, removing the old soil and supplying fresh mould to plant them in at the same time; or, if you prefer retaining some of the old trees, the best way is to train them as a low-spreading fan, keeping some of the strongest and most robust branches as low as possible—even if only a foot from the ground it would be as well, as there will be plenty of shoots from the upper side. If the trees show signs of having been unusually vigorous and gross, dig down, and prune the roots by cutting off the points rather severely, so as to moderate the growth the ensuing season. The same remarks apply to Apricot and Plum trees; only as both these answer very well trained on the spur system, perhaps some of the old wood will allow of that being done at once. But as all stone fruit are impatient of much knife work, it is better not to be too severe. You mention your wall as being low. The trees on that account ought to be further apart, to allow them to spread laterally when there is not much room upwards. But in all likelihood some new trees will be wanted, as old neglected specimens of stone fruits are difficult to bring round again. Pears and Apples might be done easily enough, and would be better than young trees; and horizontal training would just be the thing for them. But stone fruits are not so easily worked into that shape, or rather they do not bear so well when they are trained to that form, as now and then promising shoots of the preceding year being laid in amongst older wood answer well in the fan-shaped tree, but disfigure the horizontal-trained one. We hope your border is all right, and the neighbourhood of your postmark indicated it to be dry enough—a qualification which you must not increase with a vengeance by overcropping the border. You will see what has previously been said on this subject in THE JOURNAL OF HORTICULTURE.]

STOVE PLANTS IN A GREENHOUSE.

A CORRESPONDENT in a late Number speaks of having removed several of his stove plants into his greenhouse, and finds them to do very well. I have done the same this winter; of course, placing them in the warmest part. They all look well at present, except a small Tamarind tree, which I raised from a stone. This looks very bad in the winter, even when kept in a warmer house. The name of the plants brought into my conservatory in November are as follows:—Two seedling Date Palms, *Rivina tinctoria*, *Hibiscus rosea sinensis*, *Jasminum sambac*, *Loya bella*, *H. Paxtoni*, *Guava*, *Begonia macinata*, *B. fuchsoides*, *B. Saundersonia*, *Rhynchospermum jasminoides*, *Eranthemum pulchellum*, *Clerodendron fragrans*, *Caladiums*, *Poinsettia pulcherrima*, &c.—C. LERICKS.

BOILER HEATING SLOWLY.

I HAVE one of the old-fashioned conical boilers which heats three houses, and I have great difficulty in keeping out the frost in very sharp nights, as it takes three hours to get the pipes warm. I think the boiler is not set right, it being set at the back of the fire-hole; therefore it only gets a small portion of the fire, as the fire-hole is 18 inches long from the door to the boiler, there being a thick iron plate at the top of the fire, which takes the greatest quantity of heat to no purpose. The smoke passes up at the back of the furnace into a flue that circles the top part of the boiler, and leads to a chimney; therefore there is a very small portion of the boiler exposed to the action of the fire. I think the outside of the boiler should be exposed to the fire to a certain extent—say half-way up, similar to a copper furnace, then bring it into a small flue round the top of the boiler into the chimney.—P. W. M.

[The mere fact of the length of the fireplace does not prove that the boiler is set wrong. Very likely it was intended as a reserve for fuel, and the heat will be sure to go forward: that heat, however, should act on as much of the surface of the boiler

as possible. No easier plan for setting a conical boiler can be than to set it high enough on piers of lumps, so that the fire shall ply not only on the inside but the outside of the boiler. It would stand then, as it were, in the middle of the furnace; and if the bricks surrounding it, which would, of course, absorb and radiate heat, had a hollow space of 1 inch or so all round between them and the next wall of brick, little heat would be lost. The neck of the flue should be small, and a damper a short way from the furnace to throw back the heat on the boiler.

There is no more accounting for the freak of the *Camellia* you name than for obtaining two or three distinct colours from the graft of a *Laburnum*.]

POTTING *ERIDES ODORATA* AND OTHER ORCHIDS.

I HAVE an *Erides odorata* in a No. 12-pot. The roots have run down the outside of the pot, and laid hold of the inverted pot and are in the sand. It has been so for two years. If I shift it into a larger pot, I must break the roots to get them off. What is the best material to pot Orchids in? Should the soil be firm or loose?—A. M.

[There is no necessity for you to break off the roots of your *Erides*. You must get a thin-bladed knife, such as artists use to mix their colours with. Pass this blade gently between the roots and the pot they are adhering to. Probably you will find it necessary to break the pot the plant is now growing in. In that case use your knife-blade to detach the roots from the sides. Some care and dexterity will be needed to keep the roots entire; and some may be a little bruised, but preserve all you possibly can, for every root is valuable. The compost for *Erides*, *Vandas*, *Saccolabiums* and similar Orchids, consists of very fibry peat, scalded to kill the insects and weeds, and when dry break it into pieces about the size of a hen's egg; then sphagnum moss chopped moderately fine, and the dust sifted out of it. To these add some charcoal, not broken too fine nor left in pieces larger than a walnut. Let the proportions be two of fibry peat, two of sphagnum, and one of charcoal. In potting, choose a much larger pot, place a layer of large pieces of broken pots over the bottom, upon them put a second layer of smaller pieces, and a third layer of broken pots about the size of horsebeans. This drainage should occupy about one-third of the depth of the pot; upon it put some of the roughest parts of the compost. Then introduce the roots of the *Erides* into the pot, keeping the plant well up above the rim of the pot. Work in the compost amongst the roots carefully, so as not to injure them, press it down firmly, as it goes in, and so proceed till the pot is full. Heap it up in the centre, leaving it a moderate-sized hillock, which will cause the superfluous water to run off at the sides. Wet in the centre of these plants is very injurious to them. When the operation of potting is finished, have ready some tepid soft water—that is, heated to about 80°. Take your syringe, fill it with this warm water, and forcibly eject the water on the compost all around it. This will sodden down the soil, and give it a compact neat appearance. Then place your plant in a temperature of 75° to 80°, and it immediately begins to send out fresh roots, and will grow away at once satisfactorily, providing a due degree of moisture is kept up. All the points of after-culture you may obtain from the "Orchid Manual" price 2s. 6d., by T. Appleby. Procurable at any respectable bookseller's, or direct from the office, 162, Fleet Street, London.]

PRESERVING ICE.

In my suggestions upon ice-keeping, &c., in THE JOURNAL OF HORTICULTURE, there is an error, possibly an omission of my own, in page 336, where it states I filled a similar place, &c., on boxing-day, 1859; it should be 1860.

In the same Number further suggestions on the keeping ice, so to say, out of doors are invited by one of your able correspondents; and, although, having explained a practical mode of so doing previously, I will here state how it is still further a possibility that this way may yet be the more proper way than the old one.

Firstly, I will refer to one of the best so-called ice-houses that ever came under my notice. It was situated in South Wales, at Dynevor Castle, the seat of the peer of that name. It differed not in form from all others of the old make, save in

being so exceedingly substantial. The interior was in reality in the bowels of the earth or mountain, and beneath stupendous timber where rooks reared their young; and yet this place did not keep ice. It was well filled with a hundred loads; straw was used in abundance; and as it had a long passage from the outside to the interior, it was, presumably for the better preservation of the ice within, filled as firm and as full as possible with straw, fern, &c. Each time ice was wanted, so often was this passage unfiled and refilled; yet this proved of no utility. The then gardener left; and his successor, at considerable trouble, had a hole made communicating from the roof to the interior, upon which was placed a large trap-door. The doorway was served in the same way. Air, a current of the same, shot right through, and since that place has kept ice better. I adhere to it, that a cavern so highly charged with still, moist air is a sure destructive to ice.

This brings me back to the subject of straw as being the best medium between ice and air, if placed in sufficient quantity as I directed last week. Here is another mode, with which between thirty and forty loads of ice, with periodical use, were kept during the past summer at the back of a north wall. Make a slight ditch, in the middle of which make a dumb well some 2 feet all ways; make a straw wall, as described before, some 6 feet from the wall, fill it some 7 feet or 9 feet high. When done, make straw walls at each end, and cover in with a roof. Good wheat straw in thickness should be laid in between the ice and the hurdles which constitute the support of the same.

Again, in Oxfordshire I have seen to the placing of a hundred loads or so in a huge pit dug in the ground—the same being gravel, nothing being placed between it and the ice but a good layer of straw; to keep the wet from it, a thatch was placed upon posts plunged in the ground, at equal distances all round. The vacancies between these posts were also thatched in; but the pit, not being bricked or otherwise, crumbled in at each of the vacant places between the posts, leaving naturally formed air-holes, some 12 inches without any drainage, save the most effective possible—a good gravel bottom. We never had any idea of the ice not keeping. It was considered such a well-finished job at all times, the noble harvest never failed to give, what the men called, an ice-harvest-home. I knew a plum pudding placed upon that ice-house-filling table, once upon a time, weighing little short of 26 lbs.—W. EARLY.

GISHURST COMPOUND.

We believe there is no discovery that has been introduced for the benefit of gardening and gardeners which has been so much misunderstood as Gishurst Compound and its application. Some apply it in too weak a state, and, of course, they fail to attain the desired result; others err in the opposite direction, and by applying it too strong destroy or injure their plants, and thus they fail. There is another class who say, "It is a valuable thing, and I use it constantly wherever it is required; but it soils the plants so, mine appear as if they had been whitewashed." Now, all these inconveniences arise entirely from mismanagement and ignorance of the nature of the substance.

The following communication will show how it ought to be applied to trees during their season of rest, and we have frequently stated that 2 ozs. to the gallon are sufficient for plants in a growing state. To obviate the effect of stains on the foliage, it is only necessary to dissolve the Compound twelve hours before it is required, allow the solid parts to settle at the bottom of the vessel, and when it is to be used pour off the clear solution into another vessel, leaving the sediment behind. This will effectually prevent the application from staining the foliage.—[EDS. J. or H.]

"The mode of using Gishurst which I have found most advantageous with my own trees, is to take—say 3 lbs.; throw this into an earthenware pan or large pail containing about six gallons of nearly boiling water. Stir up and let this remain for forty-eight hours, by which time the strength of the smell will have passed off; then apply, by means of a full-sized painter's brush, over buds, shoots, branches, and stem, giving especial care at the forks, till the whole tree is in a white lather.

"This winter dressing may be applied from the time trees go to rest in autumn till the time the buds begin to open in spring; after that time the above strength of solution would be too great, as injury would be done to the blossoms. From one to two ounces to the gallon are then found the best strength.—G. W."

WINTER-DRESSING OF WALL TREES.

ALL good gardeners know well the benefit such wall trees as Peaches, Nectarines, Cherries, and Plums derive from having a winter-dressing or painting. The mixture generally employed is, I believe, lime, soot, soft soap, and sulphur, made with water into the consistency of thin paint, and every shoot and bud covered with it. This has an excellent effect, and the trees in spring are not so liable to the attacks of insects, or "blight," as it is often called. I never remember to have heard of a more remarkable instance of the effect of a winter-dressing than was given me last autumn by a clever gardener friend living at Winchcomb Court, near Gloucester. In the autumn of 1860, after the cold wet summer, his Peach trees were in a wretched state, the ends of the shoots curled, and the trees seeming as if they could not regain their health. Not knowing any composition fit for the purpose, and having used Gishurst Compound to his orchard-house trees, he determined to give his wall trees a strong dose by dissolving 1 lb. of the Compound to the gallon of water, and painting them with it. He operated on all but one of his Peach and Nectarine trees, leaving that untouched merely to see if any difference would be seen in spring between the dressed trees and the tree undressed. This proved to be most remarkable; the dressed trees broke into leaf healthily and vigorously, and during the summer entirely recovered from their blighted weakly state of length. The tree left undressed broke into leaf languidly in comparison, remained weakly all the summer, and is now in a poor state; the difference between it and its neighbour is very remarkable.

As a winter dressing (the trees should be painted all over) for Apple trees in gardens—such as espaliers, pyramids, or bushes infested with the American blight—the Gishurst Compound, 1 lb. to the gallon of water, which should always be soft, is a most effectual cure. Soft soap, 4 lbs. to the gallon of water, is also a capital remedy for this pest. All these compositions should be applied with a painter's brush, and every crevice filled.—T. R.

SOWING MISTLETOE.

During the last two years I have not found any Mistletoe berries containing seeds, but this year they seem to be frequent. As this may be the case in other localities, may I call the attention of your readers to a communication from "CYNET," in THE COTTAGE GARDENER of December 7th, 1858, with the hope that some may be induced to follow his directions and watch the growth of this curious plant?

Mistletoe culture requires some patience, as far as my experience goes. Interested by "CYNET'S" account, in February, 1859, when our Christmas decorations were removed, I collected all the Mistletoe berries, and squeezing out the seeds, placed them upon various trees in my garden. A few dried up and fell off, and several proved firmly (the first sign of growth), but from different accidents only one survived the following winter. This one, set upon a double-flowered Apple, for months only looked green, and stuck very closely to the bark. The glutinous substance quickly dried, leaving a clean, hard seed, which towards the end of the autumn threw out two little suckers, one on each side, which fixed upon the bark. In this state the seed remained all through 1861. In May, 1861, after an absence from home of some months, I examined my Mistletoe and found the seed-case lifted up and enclosing four leaves (each sucker, or, as it turned out, each stem, bearing two). I pulled off the shell, and this season the twin "bough" has been growing comparatively rapidly, as each stem now bears four leaves—in fact, there are now two promising little plants of Mistletoe growing rather more than half an inch apart, and a little bud has made its appearance at the base of one. Some of the berries which I placed upon an Oak were growing when they were inadvertently cut off.—FELIX-TOWE.

[More of the Mistletoe seeds probably would have vegetated if a small tongue of the bark on the underside of a branch had been raised, and a seed put underneath it.]

TO PROTECT TREES FROM RABBITS IN WINTER.—A. G. HERRIOT writes in the *American Country Gentleman* that a good way to prevent rabbits from injuring trees in winter is to take narrow strips of cotton cloth, a yard or more long (old cloth will do), and commence at the bottom of the tree, winding it around the

body till you get above the reach of the rabbits, and there tie it. Remove in spring, dry and put away for another season. If well cared for these strips will last a number of years, or as long as the tree will need protection.

BIRDS AND BUDS.

I AM a great lover of birds, and a friend to them at most seasons; but I must confess that my ire is aroused in winter and early spring when I see Bullfinches and Sparrows stripping the fruit trees of their buds. I then become their enemy and have them destroyed. An old naturalist, a near neighbour, will persist in asserting that in all the Cherry-buds destroyed by master Bully (what a beautiful fellow the male bird is, and how impudently and coolly he rapidly strips your May Duke Cherry tree, looking so innocent the while!), there is a "small green caterpillar," which, if the bud were not eaten, would assuredly destroy it. I am half inclined to think this idea is assumed, for he has never yet shown me one of the caterpillar buds, and I have never found one. The matter is rather difficult to prove, for Bully eats the very heart of the bud, and scatters the outer coverings on the ground, with many entire buds which he knocks off while at work. These, of course, offer no proof, for he has not eaten them; and my friend therefore assumes that he leaves them because there is no "worm" in the bud.

To arrive at something near the truth, I have lately narrowly watched my May Duke Cherry trees, some of which growing in a rather sheltered place a short distance from the house have been literally stripped of all their fruit-buds by Bullfinches; while others of the same age and size growing near the windows of two of my rooms, and so exposed that no bird can alight on them without being seen, while the constant passing of people by the path that runs through the lawn nearly all the day has tended to disturb birds of all kinds, are still covered with their plump blossom-buds. Well, on these trees I have endeavoured to find buds with the "small green caterpillar" inside, and I can honestly state that I have not found one. My gunner has this winter shot between three and four dozen of Bullfinches, for which I have paid him 2s. per dozen. If they had not been destroyed, I firmly believe that all the blossom-buds on my Cherry and Plum trees, except those protected by growing very near to my house, would have been destroyed.

Sparrows are more destructive to the buds of Gooseberry and Currant trees than to others; but they, the trees, are very easily protected by taking some refuse hay, shaking it up and wetting it, and then scattering it over the bushes, so that it clings to the shoots and branches. This is best done after the trees are pruned, and may remain on till the buds have burst into leaf; not a bud will be touched if this simple method of protection is employed. As to shooting Sparrows it would be endless work, and to poison them with the Wheat sold for that purpose requires much care. You may feed them for eight or ten days with sound Wheat, and then give them a batch of the poisoned; by this means you may destroy a considerable number, but their sagacity when the poisoned Wheat is thrown down in the usual way is most remarkable. Last spring in the breeding time I scattered some poisoned Wheat near the stable-door; two or three male birds fell victims the first day or so, from being, I suppose, anxious to take food to their young in the nests; but after that they would not touch it; and they even, by some wonderful instinct, taught their young ones to avoid it, for I have seen the old birds with their brood seeking for food among the stable manure among which I had placed poisoned Wheat, and not touching a grain of it. A still more striking proof of the sagacity of Sparrows, I have this moment heard from a farmer, a neighbour, not at all of a romantic turn of mind.

In the winter of 1859 he was much annoyed by hosts of Sparrows, and although not a Sparrow-destroyer his patience was exhausted. He therefore fed them abundantly for some eight or ten days, scattering the Wheat under an old Yew tree, where the ground was free from snow. They came regularly every morning to be fed, and became almost tame as they flocked to the tree on hearing his whistle. At last came the fatal moment. The strychnined Wheat was strewed under the tree instead of their usual supply; they commenced to eat in their usual hearty manner, and then came death and sickness. Many scores were picked up dead, the ground being strewn with them;

many escaped with a slight attack of seeming paralysis and sickness, having perhaps swallowed only a single grain. They were wise enough to tell their neighbours, and no more poisoned Wheat would they touch. In the following winter, 1860, my neighbour tried the same "dodge;" the sparrows came on the tree, looked askew, or, as my neighbour says, "cocked their eyes at the Wheat," and walked, or rather flew off to consult their friends. The result was they came in numbers, few and far between, to eat the sound Wheat; and at the allotted time when the poisoned Wheat was strewed they quitted in disgust, leaving only a few victims which were either too hungry or too silly to listen to the advice of their experienced friends.—FRINGILLA.

RABBITS BARKING YOUNG FRUIT TREES.

I WAS very much chagrined on going into the garden one morning lately during the severe frost we then had to find several fine young fruit trees, wall as well as standards, barked by these vermin—in particular one Green Gage Plum fully trained, fan form, very healthy, and coming into bearing. A portion of the main stem about 8 inches up from the graft barked, several of the fruit-branches partially so, three or four of the lower badly; lower-spurs bitten off, and points munched up. I know you will sympathise with me. What am I to do? Cut far back the lower branches I anticipate you to advise; but may I retain those with the points safe? Will the tree yet thrive? and what appliance would you recommend me for the main stem and branches retained? On seeing the state of matters I raised a mound of earth all round over the wounds to exclude the frost. Could you specify anything to apply to the stems of young fruit trees that will prevent rabbits barking them? as they must have got in from the lower part of the garden unwarded—a Beech-hedge fence. The most effectual, though expensive, plan would be to wire it all. What number or size of wire is most useful, its height, and what would be the best mode of supporting the wire?—AN ANXIOUS INQUIRER.

[We sympathise with you most sincerely from fellow-feelings. Rabbits were the marplot with us, and we are quite certain that all the nasty-smelling things in all the sewers of the kingdom or out of them will not long keep back a colony of starving rabbits from gnawing the bark of trees from sheer hunger, and another colony of these vermin, high fed, from doing it from sheer wantonness. Nothing is effectual against rabbits long together but fencing them off, and galvanised wire netting 18 inches wide would be the best, and cheapest in the long run, and along a hedge that width would be wide enough. The wire might be fastened to stakes or iron rods.]

MANAGING PLANTS IN A WARDIAN CASE.

I WISH to know how I am to manage my Wardian Case; it has four sides and a span roof, and a door to open at each end. In coming from London, about two months ago, the Case was turned completely over, and the Ferns almost buried. I restored them as well as I could. Some are doing well; but the earth gets covered with mildew, and most of the Ferns also. I keep the Case in the dining-room window; but I am thinking of moving it to the conservatory as being warmer for it, as I fancy it is damp cold that affects it. Please to let me know the best treatment.—L. J. L.

[It is want of air and sunlight that causes your Ferns and the soil to mildew; or, perhaps, you keep the soil too wet. You had better take the Ferns carefully up and cover the balls with soil to keep them moist; then procure some nice dryish turfy loam, leaf mould, and fibry peat, in equal parts, mix them thoroughly, breaking the lumps, if any, with the hand, but do not sift the compost; add some broken pieces of charcoal in proportion of about one-eighth of the whole. Fill the Case to the proper height with this compost, and replant the Ferns; if you choose you may place a few pieces of pumice-stone on the surface—it is an absorbent of damp. Then give a good watering, and keep the Case close for a day or two, watching that the damp is not excessive; provide for giving plenty of air daily. The small door at each end is not sufficient for air in dark damp weather; the whole roof ought to be more so, so that it could be lifted off entirely for a few hours once a-week. By having such a roof so moveable you would be able completely to dry the inside glass, the leaves of the Ferns, and the surface of the soil;

and, besides that, you could more conveniently have access to the plants to water and to take away decaying fronds and weeds, and to stir up the surface of the soil—all necessary operations for plants in any house or case, whether large or small.

Till the plants recover from their blighting and have made fresh fronds, your conservatory would be a suitable position for your Wardian Case. In any place whenever you observe dew on the glass, it is a sign or guide to you to give air directly till the inside temperature is the same as the room in which the Case stands. When the temperatures are equal there will be no deposit of moisture on the glass.]

HEATING BY GAS.

ALLOW me to ask you to enlighten me as regards the gas-burner described by "W. X. W.," in your Journal, p. 314-5. I have been for many years in the habit of using iron-wire gauze for burning gas in the way he refers to, and instead of a ring of jets, simply used a common gas-tap opening upwards in a cylinder of wrought iron 3 inches in diameter, upon the top of which was fixed, in a ring of the same diameter, the wire gauze, and it was by its own tightness secured externally to the cylinder. I found, however, that the heat was uncertain, and that the light occasionally, perhaps from want of adjustment, or altering the pressure at the gasworks, had descended to the tap and choked the wire gauze with soot. I have now come to the point which the communication of "W. X. W." leaves me in doubt about. He says that "a sheet of copper-wire gauze is to be confined in a ring or belt of about 3 inches circumference." I presume that the sheet referred to will be 1 inch diameter. "The belt is about 3 inches broad, and is suspended over a ring of jets." The article is one of great importance, and I fear that justice will not be done to his careful investigations if any typographical error has made them a little incomprehensible.—EDWARD QUIKETT.

[The word "circumference" is a mistake, it ought to be 3 inches in "diameter." I am much obliged to Mr. Quikett for pointing out the error. I have once or twice been troubled by the light descending to the ring of jets below the gauze, and found that it was owing to a defect in the gauze; also, from the ring over the gauze not being tight, and in one case from an insufficiency of air. Mr. Quikett ought to have a regulator to check irregular pressure. I consider it absolutely necessary, and a properly constructed one will effect a saving of thirty to fifty per cent. of the gas consumed.—W. X. W.]

PROPAGATION OF PLANTS BY THE MILLION.

HAVING been much interested with Mr. Beaton's Propagation for the Million, in your Number of October 1st, would you kindly answer a question concerning it in your next? Towards the end of that article Mr. Beaton says—"The cases would be merely upright pots without bottoms, and I could use them constantly in two ways—put some of my best seedlings in pots, case and putty, and put them on water; or make a ring with the top or bottom of a case on the south border, fill within the ring with cuttings, put the case over the cuttings, and a piece of glass over the top, and what would be the difference between that and my tops and bottoms?" Now, I cannot exactly see from this, whether the piece of glass on the top is to be fixed air-tight with putty, or merely placed loosely on.—B. G. S.

[Next May will be the time for the grand movement, when millions of pots are set free by "planting out." Then all the pots which are to hold forth plants for the million against the best gardeners of the age, will be each put inside another pot, so as the rim of the plant-pot or inner case rests just within the mouth of the outer pot and no more. Then the rims of the two pots will stand the fourth of an inch apart, and what little space is left open between the two rims will be filled by a bit of common clay about the size of a child's marble, but first worked between the palms of the hand till it is as soft and pliable as putty. The hole in the bottom of the outer pot will be made double the usual size with a few careful strokes of the hammer. But the aristocratic way of doing all that for the few, will be to make outer pots on purpose without bottoms at all, and to be all glazed inside and outside, like glazed big pipes for drainage. These bottomless pots, and imitations of them, are to be the

grand move for the million for striking all sorts of things under them in June, July, August, and September, and from then for Roses and ever so many kinds of shrubs and woody plants and climbers during and throughout the whole of the winter, next spring and on to soft summer-propagation again, and the bottomless will have the bottom ends uppermost, and a loose piece of glass and no putty will be the cover to keep the air pretty tight within, but not to exclude it altogether—a system that needs gardeners to look after it. This system hardly wants looking after, only it is not easy to keep oneself from always looking to it.]

MUTILATING YOUNG FRUIT TREES.

I BUGHT some young Apples and Pears, trained and standards, and asked the party from whom I purchased how I was to treat them. He told me to take a little off the point of all the branches; and on inquiring the object of what appeared to me a strange proceeding, causing a development of fruit-spurs and no wood, he said it was to encourage the wood-buds at the base of the branches. So that when I am to cut back, spring come a twelvemonth, I should make sure of plenty of wood. I bought previously a lot of fruit trees like these, finely balanced, and cut back agreeably to special instructions most unwillingly. They grew, but their fine shapes were gone. I have moved and planted hardwooded trees often, and never put a knife on them, they thrive finely. Is there any imperative law to cause this mutilation of fruit trees? What would be the result, supposing I kept these symmetrical standard beauties as they are, and the wall ones nailed on, cutting back only the central shoots for more wood? Should I be a great loser by such a cause? Please counsel.—A GREENHOSE.

[The advice to cut off a little of the points of the shoots of trained fruit trees, and the same from full-headed standards on their being removed from a nursery to your garden, was a very good advice, but the reason for doing it was against all reason. The object to be obtained from that cutting at such a time on such trees, was merely to rule the balancing powers of the roots and branches. In transplanting young healthy trees you cannot get every fibre of root up safe; there must be loss of roots, and most people would think that an advantage for fruit trees, but not for forest trees. If your trees were oaks, however, we would not cut off one inch of any one of their branches; but we would mulch the ground over their roots before the hot weather came in, and in October, 1861, we would take every one of them up again and plant them in the same places, but with as many of the roots as we could place nearer to the surface. We never prune and plant a fruit tree or bush the same day, or the same month.]

NOTES ON A FEW TENDER AQUATICS.

In order to grow stove water plants successfully, a house specially devoted to the purpose is requisite. The house should have a tank or cistern in the centre, elevated a foot or more above the level of the floor, so as to bring the smaller plants the tank may contain more immediately under the eye of the spectator. The water should be heated by one or more hot-water pipes carried through it, so as to maintain the water at a proper degree of heat necessary to their successful growth. Indeed, this is absolutely essential to success, for if the roots are subjected to continual chills failure is certain. The greenhouse species are more hardy, and will stand a little rougher treatment, but the more steady the temperature of the medium in which the roots are placed, the more certain the success, and the greater the perfection to which the plants will attain.

DAMASONIUM.—This genus contains species adapted for both the stove and greenhouse. *D. indicum*, a native of the East Indies, is an herbaceous perennial, with large, broadly cordate leaves growing out of the water; with pretty white flowers, of three broad petaloid segments, solitary, and on stalks rising about a foot or less out of the water. They appear in July and August. This species requires stove heat. Another species, *D. ovalifolium*, does pretty well in a greenhouse, and, like the last, has white flowers rising to about the same height, and appearing in June or July. It is a native of New Holland. Both species should be grown in moderate-sized pots of good loamy soil, and be placed fully a foot under water. They are propagated by seeds or divisions of the root.

ELOBOCARPUS OLERACIUS, or Water Fern.—This is a most beautiful plant, producing elegant fronds of upwards of 2 feet in height. There are no flowers, but the fertile fronds usually bear abundance of seeds (spores). The fertile or seed-bearing fronds are more finely lacinated, or cut, than the barren fronds, giving it a very elegant appearance. It is a native of the East Indies. It should be grown in large pots of loamy soil, and set in comparatively shallow water. The readiest mode of propagating is by division of the root.

BYLLIS LINIFLORA.—This is a greenhouse perennial, of from 5 inches to 6 inches in height, its linear-lanceolate leaves beset with glandular hairs, and bearing blue flowers. It is a native of New Holland. A good, lightish soil suits it admirably, with the pots not more than half immersed in water.

APONOGEION CRISPEM and MONOSTACHYON are stove species. They are bulbous-rooted, small-growing perennials. The first-named of these is the dwarfier of the two, bearing whitish flowers in July or August. It is a native of Ceylon. *A. monostachyon* has ovate leaves, and produces its flowers, which are of a pinkish hue, in a spike of about 6 inches in height. It flowers from August to the end of September. It is a native of the East Indies. Both species are very handsome. There are two greenhouse species belonging to this genus well deserving of notice, as they are even more handsome than the two I have named, which are stove species—viz., *A. angustifolium*, and *A. distachyon*. The former of these has lanceolate, erect leaves, and a dichotomous spike of white flowers, and when under proper treatment will continue to bloom nearly the whole summer. The other species, *A. distachyon*, has oblong leaves, which float on the surface of the water, and produces its white fragrant flowers for nearly three months in summer. The two last named are natives of the Cape of Good Hope. They should be planted in loamy soil, with a mixture of tuffy peat earth, in pretty large pots, and be immersed in about 2 feet of water.

ETRYALE.—This genus is allied to the Nymphaeaceae. *E. ferax* is really a noble-looking plant. The leaves are rotundo-ovate, floating, varying from 1 foot to 3 feet in diameter, according to the luxuriance of the plant. The stalks of the leaves, as well as the peduncles, or flower-stalks, and the floral envelopes, are all covered with stiff, spiny bristles. The flowers are of a reddish-pink colour. It is indigenous to China and the East Indies. To grow it successfully it should have a rich soil; loam with a mixture of road scrapings grows it well. It should be placed well down in the water. It is propagated by seeds sown in the water.

OXALIS NATANS, or Floating Wood Sorrel, succeeds very well in a greenhouse. It is a dwarf plant, seldom exceeding 3 inches or 4 inches in height. In appearance it very much resembles the common Wood Sorrel, *Oxalis acetosella*. The leaves are trifoliate, the leaflets of cordate, or inversely heart-shaped. Like the common Wood Sorrel, it produces white flowers till late in autumn. It may be grown in small pots, and if a common flower-pot saucer be filled with water, and the pot containing the plant set into it, it will be sufficient.

What more I have to say on aquatics I shall reserve for another time.—J. DUNN, *Harrock Hall, Lancashire.*

MANAGEMENT OF ICE IN STACKS AND ICE-HOUSES.

As we make advances towards refined civilisation, so do our luxuries become necessary to existence; and there is, perhaps, no more striking proof of this than the demand for ice in the summer months, since this commodity has been placed within reach by the facility of transit, which has brought the solid crystal blocks of Wenham Lake into our shop-windows at mid-summer—thus making it common to all. In large establishments in this country the demand for ice is much on the increase, and where an ordinary ice-house was formerly deemed sufficient, two are now filled, and these are aided by large stacks for early use. It has thus become an important part of the gardener's business to secure for his employer an ample quantity; and it is hoped that the following observations connected with the general management of ice for domestic purposes may not be without interest.

In the first place, the source from whence the ice is to be obtained should be, if possible, a broad expanse of water, kept perfectly clear from weeds, and from the falling leaves of trees, for nothing is more unsightly than dirty ice. The water, there-

fore, from which ice is to be procured for family use, should neither be margined nor overhung by trees, which exercise a powerful influence in preventing the surface from freezing, by arresting the radiation of heat. This may be seen any frosty morning; for the exposed portion of a pond will be covered with ice, whilst that which is sheltered by branches will not be so. Having a moderate thickness of clear ice, we will suppose it carted to the ice-house, where it should be minutely broken up, on a clean and solid floor; it cannot be too finely broken, and should be most closely packed and well rammed down in the ice-house. A large house will preserve a larger quantity (in proportion) than a small one, and it is of great importance that the situation be a thoroughly dry one. We find it best also to avoid the old plan of using straw up the sides, because when the material gets damp, it assists, like the wet blanket of the hydro-paths, in wasting the body and hastening the departure of the patient. There is an American plan, which has been successfully practised in this country, at Lord Lilford's, in Northamptonshire, and at Lord Jersey's, in Oxfordshire—on the principle of getting rid of humidity; it consists in having a small aperture in the door of the house, to open and shut at pleasure, with a corresponding one in the opposite wall. These doors are opened every night and closed again early in the morning, thus admitting a current of dry cool air, and carrying off the condensed moisture, which would hourly be exerting its wasting influence on the ice. The accompanying sketch shows the plan.

Much waste of ice is occasioned by the incautious and frequent opening of the house. This is to be avoided by the use of ice-perversers, which are now much in request, and which keep the ice for several days without waste. The house should always be opened in the cool of the morning. It will thus be seen that the main points to attain success are, to get clear ice, to pound it almost to powder, and to secure escape for accumulated moisture.

A word in regard to the situation of the ice-house may not be out of place here. It should be screened from the powerful rays of the sun by lofty trees, but may be open to the north, rather than overhung by their branches, which prevents the

radiation of the heat which the roof accumulates in hot dry weather, and generates a dampness, which is detrimental however occasioned.

Ice-stacks are made in various forms and of different dimensions, and, for the sake of economy in carriage, generally near the water, upon a sloping bank. I know a gentleman who does not break his ice for stacking, but fills up the interstices with snow and water; but this is a "penny wise and pound foolish" practice, as it is impossible to get it into so compact and solid a mass, or to make all the angles unite, so as to exclude the air. At Berkeley Castle, the seat of Lord Fitzhardinge, there is no ice-house, but the family depend for a large consumption entirely upon an immense stack of two hundred loads, which is annually stored when there is sufficient frost to enable them to do so. The stack has gone on for many years, and has never been known to fail. The situation is on a bank opened to the north, but screened by trees from the south. A platform of large rough flag-stones forms the foundation upon which the ice is broken and piled, in the form of a parallelogram, its section being a triangle, with its base shorter than its sides. When finished, it is covered with about 18 inches of thatch, which is again surrounded by large hurdles thickly thatched. This is opened without scruple as the ice is wanted, and Mr. McIntosh, the gardener there, says he would not advise any one to build an ice-house; but it is a work of great cost to get together so unlimited a quantity of ice.

From all I have been able to collect upon the subject of making ice-stacks, I think, in general, that they may be regarded rather as useful auxiliaries than as substitutes for a good ice-house—I say useful auxiliaries, inasmuch as they enable you to postpone the opening of the house till the autumnal months. At Easter and Whitsuntide, when most families resort for a short time to their country seats, some ice is wanted, and if the main stock is opened its wasting is much accelerated.

There should always be a provision for carrying off the water which is collected on the roof of an ice-house, as it should never be allowed to fall on the ground or to saturate the side walls; the best situation for it is on the side of a steep and dry bank.

Much expense in the construction of ice-houses might be

SECTION OF ICE-WELL.
The dotted lines indicate the ordinary ground-level; *a*, well; *b*, porch; *c*, door; *d*, *d*, apertures; *e*, dry rough stonework; *f*, brickwork; *g*, four-feet thickness of clay and soil; *h*, air-trap; *i*, drain.

PLAN OF ICE-WELL.
References same as in Section.

avoided by a little consideration; the common practice is to build them in the shape of an inverted cone, this form allowing the ice, as it wastes, to sink into a compact mass. They may, however, be formed square, and of a much less expensive material than bricks. A simple wattling of wood, just to prevent the ice from touching the earth, with a thickly-thatched roof, where the other conditions which have been mentioned are fulfilled, are all that is necessary. Thus, with a few simple and comparatively cheap and rustic materials, and a little knowledge of the laws which govern the diffusion of heat by absorption and radiation, the owner of a villa residence may be enabled to enjoy, in common with the owner of the princely palace, a store of ice, and there can be little doubt but that such will soon be the case.

If the hints here thrown out should be instrumental in promoting this object, the writer will feel that his attention has been directed to a useful end.—H. BAILEY, *Nuneham Park*.

NOTES FROM CUMBERLAND.

MAY I trouble you with the following remarks and questions? I am very fond of flowering shrubs, and get all the good hardy ones that I can meet with.

I am, in turning over an old volume of your *COTTAGE GARDENER*, to see a most flaming description of *Indigofera dosera*

(new flowering shrub), vide August 10, 1858, page 291: you there describe it as 4 feet high and 6 feet round, and perfectly hardy, certain to become as standing a dish in every collection as a Rose. I now find by looking back to my diary of that date that I then determined to get it when available. I got lists from a great many of the leading firms, and never could find it mentioned until looking over Carter's seed catalogue, which I received last night; it is therein described as greenhouse shrub, 1 foot high. Perhaps Messrs. Paul, where you saw it, might briefly tell us whether it proved hardy or not. It may be lost and gone since your notice.

We have no florist or dealer in ornamental shrubs in this county—none nearer than Edinburgh or Liverpool, each one hundred miles or more distant. We certainly have two or three very fair nurserymen, as far as Larches and Spruce Firs are concerned; but there their knowledge of arboriculture ends. I have sometimes ordered a plant through them, and invariably found that I have paid at least six times the proper price, and generally got the wrong article. A clerical friend of mine, the best florist in the country, made a calculation the other day, and found that if we wanted above £5 worth of good and new things, instead of buying or ordering them at home, we could save a considerable part of it by going to Dicksons of Edinburgh, or any other good firm, there enjoy ourselves for a day or two, see all the best and useful novelties, and bring them away with us. I have frequently sent several pounds going after plants, which, when I found, only cost a few shillings; but I had the satisfaction that I had the real article, besides the opportunity of looking at the bottom of the pots to see if there were any roots or not, which I am sorry to say is not always the case. This county is rapidly improving with respect to gentlemen's seats, &c. In the lake district handsome villas, belonging to retired tradesmen, are springing up like Mushrooms. I have visited several lately, and they all have to get their shrubs from Skirving, of Liverpool, or Peter Lawson, or Dicksons of Edinburgh; certainly they could not deal with more liberal or better people, but it is a long way off. I firmly believe that any enterprising man starting the above business in Cumberland would make an immense fortune (honourably) in a very short time. There is a rumour, certainly, that a very large and excellent firm in the seed and forest-tree line are going to start the florist and ornamental shrub business, and sell at London prices. I wish this may turn out to be the case.

I have had many dealings with Dickson, Downie & Laird, &c., and have always met with the greatest liberality. I also find that any novelty got from the north does better here than the same plant from the London or south country establishments.

About two years ago a gentleman in the train along with me near Edinburgh had a bunch of a plant in his hand which attracted my attention. To be brief, he gave it to me, and I transferred it to my button-hole. He called it *Calceolaria violacea*. I saw nothing like a *Calceolaria* about it; but I mentioned it to my friend Mr. Alexander, the head of Dickson's house, who said that the name was correct, and that there was then a splendid plant of it in the Experimental Gardens in Edinburgh. I understood it was not in the trade. I gave half of my sprig to a friend as I passed through Carlisle. Next day I stuck mine into a flower-pot in the greenhouse, it struck immediately, and grew amazingly that season (this was about May). Next spring it began to stagger, but sent up several suckers. Should I then have headed it down? I let a Baronet's gardener in this part grub away at it with his knife for a sucker, after which mine died, and he either lost on his road home, or forgot to plant, the suckers, so I have entirely lost it. I have never seen it advertised in any list, though I have looked for it very carefully. Does it want any more than greenhouse heat? In an old Number of your work, I last night stumbled upon a notice of it, vide page 308, July, 1856, "Recollections of Raith." Any account of its treatment would much oblige, as I never saw a more beautiful or useful-looking plant.

I saw some of your correspondents a few weeks back made some inquiries about the Osage Orange. I sowed some seed about three years ago, some from Carter in pots in a frame, the rest from Little and Ballantyne, of Carlisle, in a drill like Peas; I believe every one of them came and offered to make a fine hedge very soon. The garden-door being left open some hares rushed in and ate the whole row clean off; I had then no gamekeeper, and had a great number of hares running about. I have a very fine plant or two four years old against a wall; but I do not think it will ever

either fruit or flower; it seems perfectly hardy as it stood our two last winters. But, certainly, I was much favoured, all my shrubs being buried in snow for eight or nine weeks last winter. I have a large plant of *Benthamia fragifera* in the greenhouse which is becoming a nuisance. May I venture to plant it out next spring? I should like to see it fruit as described.

If these remarks are not too tedious and troublesome to you I should like to ask for a little information about bulbs, and, at the same time, commemorate their progress in this outlandish part of the country.—GROUSE.

P.S.—There is a new nut now in our fruit-shops called *Sapuecia Nut*, stated to come from Mexico, about an inch long, taste something between a Beech nut and an Almond nut; I should think too oily to be wholesome. Scores of my friends have been at me to know what sort of tree it grows on, and vote that I am losing my faculties because I cannot tell them all about it.

[We know little more of the *Indigofera* than what is noted at the page you refer to. We would advise your trying a packet of seeds from Messrs. Carter, and after a season's growth and keeping the plants in a cool greenhouse in winter, plant out some in the shrubbery next season, some against a wall, and others to be kept in a cool greenhouse. We do not think it is at all common to find country nurserymen overcharge for a new thing—in fact, the price ought to be about the same, with the extra price of carriage; and then there would be the difference of retail and trade price to make amends for the trouble—in fact, as a general rule, respectable country nurserymen supply things at the same price as the holders would do, and frequently when it is undesirable to have a number of small bills, it is best to get a new thing in this way. But for the number of bills it would, on the other hand, be desirable to get it at once from the holder; but, even then, if there be a great demand, we must be satisfied with less than getting pots so full of roots as to show themselves at the bottom! We wish all our metropolitan tradesmen the fullest success; but we cannot help wishing the same to all country nurserymen. And altogether we believe that on the whole each and every one of them are anxious to do the best for their customers, because all intelligent people are aware that honesty in such matters, as in all others, is the best policy. Time with all such, whether in town or country, is money's worth, and therefore we are glad that so many, like our correspondent, give a little order to compensate for the time of a sight and attendance. For ourselves we would visit nurseries oftener; but, because we buy or can purchase little, we do not feel it right to rob tradesmen of their time for nothing. So much is this looked at that some who grow for market never wish to see a visitor on their premises.

The *Calceolaria* used to be common enough; it is a fine thing—quite a mass of small flowers. Your plant ought to have bloomed in April and May, and then you should either have struck cuttings or sown seeds. We have seen it frequently since it was noticed at Raith, but not for two or three years. We think, most likely, that the digging after the suckers destroyed the plant. The greenhouse is quite warm enough for it. We should judge it was best treated as a biennial—grown one season and flowered the next.

Try *Benthamia fragifera* against a wall, and cover with moss at the roots, and put branches over the top in winter.

We shall be glad to give and receive the information about bulbs, when convenient.

Lycythis altaria, says Dr. Hogg, in his "Vegetable Kingdom," is a tree 60 feet high, and produces the Nuts called *Sapuecia Nuts*, which may of late years be frequently met with in the fruiterers' shops of this country; in Brazil they are called *Jac-pucaya*. The fruit is very hard, as large as a child's head, and furnished with a lid, which falls off when it is ripe, and the dry pulp and seeds also fall out; but the pot, or capsule, frequently hangs on for two years afterwards.* Each of these capsules contains a number of Nuts, which are about 1½ inch or 2 inches long, slightly curved and grooved, being in shape somewhat like a small Girkum Cucumber, but of a light brown colour. The shell is soft, and the kernel is very mild, mellow, with a sort of cream or custard flavour, and may be eaten either raw or roasted. The bark of the tree is easily separable into distinct layers by breaking it, and then the layers divide so neatly from each other that, when separated, they have the appearance of satin paper.†

You are quite right in considering them very indigestible, so

* It is called Monkey-Pot on account of its shape.

much so that if eaten uncooked they are apt to cause headache and giddiness. Roasted they are less injurious. They are imported exclusively from Para.]

CUCUMBERS INJURED BY FUMIGATING.

I AM growing some winter Cucumbers on hot-water tanks in a house with a roof. I have them back and front. I ridged them out on the 8th of November. A few days after I perceived thrips on them. I had them fumigated twice a-week with tobacco-pape for the first month, which did them no harm. The next fumigation they got, I perceived the leaves of some of the plants, which had reached highest, injured; they were as if they were scorched. I wish to be particular. The tobacco-paper was in an open pot, and the material it was ignited with was charcoal. I questioned the boy who fumigated, who said he did not let it blaze. Seeing in your Journal that brown paper was a good thing to light tobacco with, I tried it, and found it did well. I was so much afraid that I went into the house, and saw it done, and kept the smoke from coming in contact with the plant that was directly over the pot by scattering it with a fan. A few days ago I had occasion to fumigate again. I happened to have some cocca-nut fibre that I took out of some Cocca-nuts. Not having brown paper, I tried this, and found it would not blaze. I got it ready in my pot, and put the tobacco-paper in on it. I got the boy to come in with me; he blew it, and I, as a precaution, fanned the smoke to keep it from striking too strongly the leaves overhead. The next morning I syringed with tepid water. The day became bright, and I noticed the plants to flag, and perceived two or three of the front plants many of the leaves very much injured, quite blighted, and more of the edges of them crisp, and one in particular, the furthest from where we fumigated, the most injured. I wish to mention that the back ones were not in the least touched. Could it have been that I did not syringe them enough, or that the day was bright and they wanted water? Or was it in the first instance the charcoal, and in the second, was it the cocca-nut fibre? I wish to mention that in my house the heat at night averages from 56° to 62°, in the day 65° to 75°, as far as I have gone this season, with ventilation by a pipe that passes through the bed with three escapes, and the ridge of the roof opens when required. On the former occasion the back plants were not injured: I thought it arose from their not being so much grown as those at the front; but on this occasion they are as high as some of the parts injured on the front plants. It was all the large and older leaves that sufficed; the young ones are not the least touched.—P. KIRBY.

[The roots must not touch the tank, or you will have the leaves flag whenever the sun comes out. All plants are more tender in winter than in summer, and, therefore, will stand smoking less. The younger leaves as having more vitality will suffer least. We would always use tobacco instead of paper in winter. If burned in a pot or any other vessel the top should be covered with a thick layer loosely put on of damp moss, so that the smoke shall be cool before it reaches the plants. The plants against the back wall would not be so liable to suffer as those near the glass. When the thrips were first noticed, it would be the best plan to catch them and kill them. This is not difficult to do, as they invariably congregate on the lower side of the under leaves. A lad with quick eyes would soon clear all the leaves by daubing the point of a wet finger on each jumping rasal, and thus squeezing them. You may do the same by sticking them into a damp piece of sponge. They require frequent smoking to destroy them. After smoking, the plants should be shaded from sun for several days.]

SOWING CATTLE CABBAGES.

You recommend sowing the seed of the Drumhead Cabbage and others, and then planting the seedlings out. To save all the trouble of watering and planting, I have always dropped the seed on the top of the balk, as I do Mangold seed, with this difference—I make my man take the seed in a tea-cup, and beg of him to keep his fingers dry, and endeavour to drop only three or four seeds on the surface, and then just give it a rub or a gentl scratch with the finger, and then stride on a good yard and drop in three or four more. In this way a man will stride over a large piece of ground in a day. The seed cannot be put

in too shallow—just covered is enough. The probability is they will all grow, and when 5 inches or 6 inches high I single, leaving the two best plants, and after a time remove the weaker of the two, and you will have fine, strong plants with leaves feathering from 2 inches or 3 inches from the earth, instead of long-legged Cabbages tumbling all manner of ways. The plants should be 3 feet asunder every way if possible. If the land is well manured you will have immense Drumheads, without any check by transplanting. I have tried this way, and it is a good one for all winter greens. At page 38 you say the longest-kept Mangold you ever knew was twelve months. A friend of mine kept a Mangold Wurtzel three years in a cellar pretty good, but shrivelled, not rotten. He examined it every Christmas-day.—W. JOHNSON, *Watlington Cottage, near Downham Market.*

HAMILTON PALACE GARDENS.

EXTENSIVE operations have been going on here within the last twelve months. New and commodious kitchen gardens have been laid out, and two very large ranges of forcing-houses have been erected by Mr. Gray, horticultural builder, Danvers Street, Chelsea. The upper range, consisting of six vineries and two Peach-houses, some 370 feet length in all, are pretty well completed; while the lower range, comprising pincies and Peach-cases, are nearly as long as the upper one, are fast approaching completion, and from the sloping character of the ground presents a *coup d'oeil* of imposing magnificence. The interior of the houses shows at once their extreme commodiousness, horticulturally speaking, more of which at some future period; while the workmanship gives evidence of strength, durability and neatness, reflecting considerable credit on the unwearied exertions and skill of Mr. Mitchell, who seems anxious that the noble house of Hamilton should have a garden in the broadest sense of the term in keeping with their spacious mansion and extensive demesne.

The former gentleman who, by the way, was once a gardener, anxious to have a social evening's enjoyment among the fraternity, invited, with the permission of Mr. Mitchell, numerous gentlemen both in the "trade" and profession to inspect his labours; and the invitation, as might be supposed, extending over a considerable circle of country, was generally responded to, and all expressed much pleasure and satisfaction at what they had seen.

In the course of the evening Mr. Gray remarked, he was exceedingly glad to be honoured with the company of so many first-class gardeners. And in reviewing his past life he further remarked that he was journeyman at Colness, then but a very obscure place; but, strange to say, he had three fellow companions. One died comparatively young in Australia, the other now lays in the churchyard of Arundel (George McEwen), and the third was a guest at that table—Mr. Shearer, Yester. He attributes his own success not so much to his own abilities, "for he never could work a rafter in his life," as to watching his opportunity—biding his time. Take cognisance of this, young men, that tact, perseverance, and probity, often make a humble aspirer a really successful man.—J. A.

WORK FOR THE WEEK.

KITCHEN GARDEN.

Artichokes, Globe, sow in heat, and transplant into boxes, to be finally planted out in April in deeply-trenched and well-manured ground. *Artichokes, Jerusalem*, make preparations for planting them. Rich manures to be given, as they abound in nitrogen. *Capstevans*, seeds to be sown in pots, and placed in heat. *Carrats*, if a sowing has not yet been made it should now be done on a slight hotbed, and covered with hoops and mats, or a frame, which may be removed in a month or six weeks if wanted for other purposes. A little *Camelliflower* seed may be sown on the same bed. *Kidney Beans*, a crop now sown in small pots, and when of sufficient size planted into a large pot where a command of heat can be had, will produce more abundantly than those in pots. The introduction of the red spider into the forcing-house will also be avoided by adopting this plan. Keep those in pots well watered. *Mushrooms*, beds for early crops should now be made; the horse-droppings must be previously well worked to prevent their attaining a burning heat. Keep the dung well beat down at the time of making. *Peas*, when the weather will permit, draw a little

earth to the early crops, which will now be on the move; and if bleak inclement weather prevails, they will be benefited by the shelter of a few fir branches stuck on the bleak side. Continue surface-stirring, and watch opportunities for the destruction of slugs, which, if not kept down, will soon commit sad ravages amongst the young crops.

FLOWER GARDEN.

During fine weather like the present regulate herbaceous plants, reduce *Phloxes*, &c., where they require it, and replant them after well digging the ground, taking care not to plant them too thickly. Where tree *Pæonies* are not growing freely, much good might be done by taking them up carefully, and digging holes from 3 feet to 3½ feet deep and from 1 foot to 5 feet wide, to be filled with a compost of well-decomposed dung, loam, and peat in equal proportions. If the bottom is wet it should be drained, as stagnant water is certain to destroy their long fleshy roots. Where choice shrubs are not growing vigorously, examine the roots, and if they are not in a healthy state, fork out and trench around the extremities of the roots, and replace with fresh soil suitable for the sort of tree or shrub. As there is no appearance of frost, *Moss*, *Provence*, and other hardy *Roses* may now be pruned. Cut out as much of the old wood as can be conveniently spared, and shorten back young wood to the most prominent buds. The sooner that all *Roses* are planted now the better, except the more tender Chinese kinds. Examine shrubberries, and cut out all dead wood from the shrubs, pruning such as require it with a knife, or mallet, or chisel, but not with a saw, unless the cut is made very smooth afterwards. Roll, sweep, and clean gravel-walks as often as practicable. Weed *Box*, *Gentian*, and other edgings in mild weather.

FRUIT GARDEN.

Planting in every part, while the weather is mild, both against walls and in open quarters, should be completed without delay. Mutch the newly-planted trees, and stake those requiring it at once. Prune and nail *Apricots*, and continue the same with other wall trees not yet completed. Where *Filberts* are brought under the influence of the knife and spade, which is by far the best method of cultivating them, let all suckers be carefully removed, and some manure forked in about the roots. Shorten all the strong shoots of last year's growth, but do not interfere with the small ones, as it is from them the nuts are principally produced. It is also advisable to thin out some of the larger branches where they are too thick.

STOVE.

Some of the plants will now begin to grow, and consequently, must have an increase of water. Pot *Cinerarias* if they require it, but without disturbing the ball of earth around their roots; give them an increase of heat if it can be conveniently done. They require large supplies of water during their growing period. Pot *Erythra cristagalli*, previously shaking their growing period. Pot from their roots, place them in bottom heat until they begin to shoot.

GREENHOUSE AND CONSERVATORY.

At every opportunity, when the external atmosphere is dry and rather warm, admit air freely to dry the plants. This will be the means of saving many a valuable leaf and branch. Shake out the old plants of *Fuchsias*, reduce the roots, and re-plant them. Introduce them to a temperature about 60°, and as soon as cuttings an inch long can be obtained strike them, and grow them as quickly as possible, to produce fine specimens before they show bloom.

PITS AND FRAMES.

Should lights become green from damp or other causes, take advantage of the weather, and have them washed, it helps to strengthen the plants at this dull season by admitting more light. Surface-dress the pots, and pick off all dead leaves. Place in heat *Lobelia fulgens*, splendens, and ignea, to pot off about the middle or end of February. *Calceolarias* which were put in last October will now be fit for potting off, and if any are not well rooted, to be placed in store-pots, and introduced to a very gentle heat. Place in heat the various sorts of *Salvias*, they make fine showy plants in the borders in autumn. The sooner they are struck now the better; they should be potted off as soon as they are struck, and grown in heat during the spring, to make strong plants for turning out into the beds and borders. *Dallias* of choice sorts, from which many young plants are required, may now be potted and placed in heat, or they may be laid in any warm place, and partly

covered with leaf mould or any other light soil. Sow seed of *Thunbergia*, *Phlox Drummondii*, *Rhodanthus Mangliesii*, *Salpiglossis*, and other such annuals which require to be cultivated in pots for some time before being planted out in the open borders.

W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

Wheeled and trenched in frosty mornings, and turned over ridges previously turned up to get the benefit of the frost and air. Examined *Lettuces*, *Cauliflowers*, &c. Removed the remainder of *Cauliflowers* housed in autumn for winter use, and put them in a shed, the dozen or so left being scarcely worth the trouble of protecting, and *Snow's Broccoli* is knotting nicely in the quarter, with a little stubble beside it ready to throw over it on a frosty night. Kept mice from Peas by a thick cover of barley awns. Chopped furze is better still, when it can be got. Stirred up soil with a stick in *Radish-bed*. Packed up leaves round *Cucumber-frame*. Placed more *Rhubarb* and *Sea-kale* in the *Mushroom-house*; earthed up small bed that had a good portion of dry sods chopped with it, to help and dry it, the dung of all kinds being apt to be too wet at this season. Dry straw cut or chopped into inch-lengths is good for the same purpose. *Mushrooms* have been plentiful enough, but our shallow beds, individually, have seemed to bear freely for a shorter time than usual this season, which I attribute to not having so many droppings as before. In this, however, I may be wrong. I have also, to a great extent, given up surfacing the beds before earthing them with thick cowdung a little dried. There was a complaint that the *Mushrooms* were so thick and fleshy that there were no means of cooking them thoroughly, so as to get the centre as tender as the outside. Gave plenty of air to *Cauliflowers*, &c., unless in frost. *Fraser's Plain-leaved Batavian Endive* is still standing well, having received only a little protection in severe weather. What is under the dry stubble and leaves is in excellent order. Blanched *Turnip-tops* are not so much-cared for this season, as there is plenty of all green stuff as yet.

FRUIT GARDEN.

Pruned *Apples*, *Plums*, &c., what little they needed after nipping-in in summer. Pruned and nailed hardier fruit trees. Looked over *Strawberries* in pots. Damped *Vines*, &c. Syringed *Peach* trees in first house, especially in the middle of the day. Gave fresh soil to some old *Cherry* trees that were becoming exhausted from heavy, continuous bearings, and a little rich compost to *Pears*, *Apples*, *Currants*, and *Gooseberries* that were planted last year, applying it now as a top-dressing. Whenever the birds begin to touch the buds, will smother them with soot and lime made into a wash with *soapsuds*, and applied thickly with an old syringe, having just as much clay in it as to make it stick to the bushes pretty well. Sowed *Melon* seed in *Cucumber-bed*.

ORNAMENTAL DEPARTMENT IN-DOORS.

Potted *Gloxinias*, &c. Now is the time to assist *Gardenias* with moist heat, alike to encourage growth, swell the buds, and destroy the insects. All plants of a hardy character, whether shrubs, herbaceous plants, or bulbs, that have been treated to a hotbed, should be gradually hardened before being moved to the greenhouse or sitting-room, and the heat when given should be applied gradually. We have seen hardy plants brought in frosted, and placed at once in a hotbed, which is just about as wise as putting frozen *Cabbages*, or a frozen leg of mutton into boiling water. Most plants must be kept rather still at this season, and heat regulated according to the amount of light, and that has not been much lately. The greenhouse should be watered with care, and just enough given to prevent *Camellias* and other flowering things from throwing their buds. Removed a lot of *Salvias*, *Primulas*, &c., and replaced with *Cinerarias*, spring flowers, and *Geraniums* coming on, keeping the house as yet cool and airy, and thus preventing the appearance of damp, &c.

Out of doors, in pits, &c., bedding plants have had plenty of air and light after the frost went, pulling the lights off *Calceolarias*, &c., in fine days; and when there was any likelihood of rain, giving air back and front, but so as to keep the damp out. The *Calceolarias* inserted in October are with all this care getting rather thick, and I do not want to thin them out for another month if possible. The late *vinery* being now cleared, will have the *Peach-house* emptied of all the common *Geraniums*,

the small plants of the variegated ones being left to grow bigger, and those from the Peach-house will cram the vinery from back to front stages, floor, and altogether; each and everything in that way, except Calceolarias, which will be all the better if they never see or feel fire heat. This sets frames, &c., at liberty for some time and for propagating, and these bedding plants will be easier kept, where a little fire heat can be given than by covering out of doors. Some of the forwardest Pelargoniums will also be moved to the same place.

Our Cannas were considerably frosted last autumn, but, standing on the floor of a house, they seem to be growing again well. They did not make such good foliage last year as they usually do; but several varieties of *Ricinus Palma Christi* made splendid leaves; and for a central plant or solitary specimens a correspondent lately did not say a word too much in their praise. Seeds should be sown next month (February), so as to have the plants potted off and strong before May.

In the pleasure-ground, turning, sweeping, rolling, &c., so as to keep all nice.—R. F.

TO CORRESPONDENTS.

* * * We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to The Editors of the "Journal of Horticulture, &c.," 162, Fleet Street, London, E.C.

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

We cannot reply privately to any communication unless under very special circumstances.

MONTHLY CALENDAR (*H. Milne*).—We try to please everybody as well as we can, but if we were to have two calendars it would take up too much room. We think, however, that a great proportion of the operations done around London in February will be done time enough in Lancashire in March. We think that our "Calendar" would suit many readers best. Although we do not see our way clearly to comply with your request at present, we will keep it in mind.

LARGE GERANIUMS IN POTS (*H. B.*).—We have no personal experience of the pastels you name. We generally are a little shy of most new things until we have tried them by degrees. See what is said to Kirby about planting. See answer to correspondent last week to Mr. Fish's large Geraniums. The pots are some 14 inches. The object is to get from them a great mass of bloom all the summer, and hence they are merely kept alive in winter. In some cases, to get a good show in winter you could not do better than the plan you adopt. As a general rule, the large and horsehoe kinds answer best for that purpose. Mr. Fish's plants are Tom Thumbs. But for the room in winter he would have more of them.

LAYERING APPLE TREES (*C. H. W.*).—We have a great notion of layering such trees, though a few kinds may do well. For ourselves, if ringing at all we would take off a ring of bark 1 inch wide as soon as the flow of the sap would enable us to do so, and tie a piece of calico or paper over the part. As soon as the leaves begin to expand we would lay the part in a pot of soil, and remove it as soon as it was supplied with roots. Where this plan would not suit, or be apt to make the shoot to crack, we would merely remove the bark on one side and twist the shoot, or perhaps slit it up the middle, and plant the whole bit of wood between 1 1/2 slits to prevent them coming together again. You will no doubt thus obtain very dwarf trees.

PRAIRIE TREES SHEDDING THEIR BLOSSOM-BUDS (*R. J. W.*).—There is nothing so likely to cause this as the trees being allowed to become too dry in the autumn, and then to have had a free watering at once. If that watering is needed it should be given by degrees by making holes in the soil.

CYCLEMEN VERNUM (*Halesleigh*).—Your *Cyclamen* is the true *vernum* at last, having the leaves of persistent very nearly and the flowers of *vernum* at least, much larger and much lighter. But have your "roots," the family crest first mentioned by Sweet in his "British Flower Garden," vol. 1, plate 9, thus?—"The leaves and flowers are produced on a kind of short flat stem that is hollow, and the tuber, not the diploid, is the proper and true one, as in *perisperm* and *coronaria*." Our individual tuber of *vernum* has this family crest, but the crest went blind before we had it. After that another "short flat stem" has been made from the middle of the side of the old tuber, and that is now in seed—two pots, but yet very small ones. Mr. Deaton would be particularly obliged for a tuber from you, and one out of pots while at rest; therefore his *vernum* flowering three months later than it did in Miller's time, or in Gordon's practices, or in our own experience, is not to be wondered at. The new race of *Cyclamen* obtained by Mr. Atkins between *coronaria* and *perisperm* have now spread into a large number of pots, and some of the best are, and some are as like *vernum* as can be, except the family mark of producing leaves and flowers on a short blunt spur above the tuber.

ORONDIS (*W. H. M.*).—Any of the first-rate nurserymen who advertise in our columns can supply; or, We cannot recommend any one.

HEXAGON GARDEN NETTING (*J. C. C.*).—Mr. Haythorn lives at Notting-ham. His advertisement is in our Journal to-day.

CUTTING DOWN SICKLY HOLLIES (*H. X. W.*).—The best time for the operation is at the very end of April. Cut them down level with the surface, or even rather below it.

GREENHOUSE ANNUALS TO FLOWER IN APRIL (*T. Cross*).—*Collinsia bicolor* and others; *Nepheola insignis* and others; *Mignonette* (if sown in heat); *Virginian Stock*, white and pink; *Musk* taken up, and potted, and placed in heat. Treat all the others in pots in the temperate part of the greenhouse. Treat many other annuals that will come in later, but these will bloom by that time with ordinary attention.

LAPAGERIA ROSEA AND DESTONTAINIA SPINOSA (*Sunderland*).—See answer to "CLERICUS." Drain the pot extra well, and plant in fibry loam and heath soil in equal proportions, with about a fourth part of fine leaf mould and the same of sand (silver), and bits of crock. Use rather a large pot, and place the top exposed. Similar soil without the leaf mould for *Destontainia*, and rest for a time when the growth is made, and increase the temperature as the plant commences to grow afresh.

LUCILLA GRATISSIMA AND LAPAGERIA ROSEA IN POTS (*Clericus*).—The *Lucilla* and the *Lapageria* can be grown very well in pots, and in the mode you propose. Fibry loam and heath soil, with good leaf mould and a fair proportion of sand suit them well. The reason why a border when suitable is recommended is that the roots do not like sudden changes or frequent mutilations: hence, when grown in pots the shifts should be rather large for the plants, and the soil given with care, so that the roots get into it. And then in summer and autumn, the roots, if close to the outside of the pot, should be protected from great heats by the pot being partly plunged, or a piece of mat or cloth put round it, or sunk partly or wholly into another pot, with moss at the top to keep a hollow space between.

PLANTS UNDER AN ARBOR VITAE HEDGE (*A Bath Subscriber*).—Of all things you can put in the border under the *Arbor Vitae* hedge, grass turf will do the least harm to the *Arbor Vitae*; for they of all other fence plants suffer least from having turf over the roots instead of a bare surface border which never rotted in the same border close to *Arbor Vitae*. Hedges of *Arbor Vitae* are most beautiful fences where they are done justice to, as we advise for yours; but they are most unsightly things if they are not treated properly, which they never are when they get only one share of the goodness of their own border. But seeing you do not wish to have your own way, we confine the whole length of the border on both sides of the hedge to spring-dwelling bulbs, and you will never repeat it.

NAME OF FRUIT (*G. P.*).—Your Apple is the Norfolk Beeching. The spots upon it are fungoid attacks, occasioned either by the season, or from the roots having got into bad soil. The latter appears to be the cause, as the Pear is very sensitive to an evidently suffering from the same affection. How is your situation? If that is not good, on such stiff clay as yours is the fruit would present that appearance.

NAMES OF PLANTS (*H. M. J.*).—1, *Pteris hastata*; 2, *Polystichum aculeatum*; and 3, the variety *lobatum*; 4, *Lastræa dilatata* apparently—but you have set the wrong "half of the frond," the lower part with the scales of the stem being necessarily to certain extent in naming; 5, *Asplenium adnigrum*; 6, *Lastræa dilatata* *collina*, not fully developed. (*J. P.*)—The flowers you enclose are of *Chimonanthus fragrans*.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

POULTRY, &c., SHOWS.

FEBRUARY 5th and 6th. LIVERPOOL. Sec., J. T. Lawrence, 3, Cook Street. Entries close Jan. 21st.
FEBRUARY 7th and 8th. NANTWICH. Sec., E. H. Rhodes. Entries close Jan. 25th.
MARCH 1st. HALIFAX. Sec., Mr. J. W. Thompson, Southwram, near Halifax. Entries close February 20th.
MAY 14th and 15th. TAUNTON AND SOMERSET. Sec., Charles Ballance, Esq., Taunton.
MAY 27th, 28th and 29th. BATH AND WEST OF ENGLAND (City of Wells). Steward, S. Pittman, Esq., Manor House, Taunton. Entries close May 1.
JUNE 4th and 5th. BEVERLEY AND EAST RIDING. Sec., Mr. Harry Adams.

CHRISTMAS POULTRY MARKET.

(Continued from page 364.)

It is said that circumstances bring men out, and with many the purchase of the Christmas poultry is no light matter. They come by shoals during this week, and spend hundreds of pounds. They are self-sufficient men, and coming at a time when their spirits are buoyant, they form an amusing study. They never come alone, one or two friends accompany them. The retail shops in a wholesale market are beneath their notice; and when a friend expresses a faint doubt of their judgment, or remarks on the absence of any right to complain if they are taken in or imposed upon, they only affirm that such a thing is impossible. Then they enlarge on the iniquities of retailers, and the advantage there would be if it were possible for consumers to buy everything wholesale. They are careful to ask the price of such things as they purpose buying on the road to the market. We will go with such a one and his friend for ten minutes, and buy the Christmas poultry. "Our people," as he condescends to term his employers, give beef to all who work for them, and he has settled to have boiled fowls. His wife informed him when he returned from business, that for two such as he would like

they had asked eleven shillings. His indignation was boundless, and he'd be kicked if he wouldn't soon turn tory, and wink at all sorts of abuses—a tariff for instance, of all catables, so that a woman might go to market without fear of being imposed upon. Eleven shillings! it was too bad, by Jove it was. "Well, but," says his wife, halting in the operation of stirring the pudding, "what is to be done? Are we to go without?" "Without! No." Being Christmas-eve he has left office early, he will call for a friend, and they will go to Leadenhall.

This eve is unlike all other eves, and such a one who never exceeds his pint of half-and-half per diem, who thinks wine and the insolvent Debtor's Court twins, on this occasion such a one will accept or give a glass of sherry without even a twinge. Our friends have had several glasses, and, of course, each has a cigar in his mouth.

The buyer carries a blue bag in his hand. After he has turned out of Gracechurch Street, and is going to the market, there is time if he should alter his mind. Retail shops are on each side of him. He feels playful, he asks the price of fowls at every shop—none of your shabby little things, but a pair of good big Surrey fowls. Everwhere eleven shillings. He would be angry, but it is Christmas, and he cannot. He turns into the market. At the first shop on the right, large fowls are heaped on the lid of a hamper. He asks the price of two of them, they are very large and so fat. "Seven shillins per couple." His elbow visits the ribs of his friend. "There, what did I tell you?"

Children like puppies and kittens better than grown animals, because they can patronise and govern them; and if a man of the class of the buyer with whom we are now associating takes a friend to witness the display of his acumen and *savoir-vivre* he will cautiously avoid even an equal—he must be an inferior, and he would bring a dependant if he had one. Friend has his doubts about quality: he dares not whisper them, and therefore, like greater men on greater occasions, he says, "Ah!" Buyer is not content, he will try elsewhere; and it is not till he has been round the Market, and has been told in answer to the inquiry about the price of two good fowls that he may go to Bath—worse still, to hang himself, or he is invited to come next week, or reminded that there is a pump in the court, that he makes up his mind to return to the first stall. (*Mem.*—A salesman does not keep a shop.) He has not been a hero in the eyes of his friend, and finds he has to make up lost ground. He therefore returns, and says he will have two of those fowls, and desires the salesman to pick him two of the best. He gets no answer, and the salesman walks away. This is not making progress. He tells his friend he did not hear him, and follows up till he is informed if he does not have them at once he shall not have them at all. He goes to select two, and is told not to pull them about, but to take them as they come, and at last he does so. He has not risen in his friend's estimation. The latter ventures to doubt the quality of the fowls; and this ends in buyer's doing that which he never intended—asking his friend to dine with him. He did not intend it, but it should be seen whether he was not a judge of poultry. What a storm! Luckily "our people" gave some beef, or the party would have been dinnerless. Buyer had misgivings when the cover was removed. Instead of looking round, plump, and white, and of being well seated in the dish, they were angular at top and round at bottom. They would not lie still in the dish—they rolled about; their breasts were every shape but the right; the stumps of their legs protruded through the skin; and, spite of all the efforts of white sauce, the fowls were decidedly yellow. Their appearance gives him a shudder, and, like a skilful general, he looks to his rear to secure a retreat. He mutters something about badly trussed and boiled at a gallop. It was well he did—they were uneatable. He lost ten minutes and his temper trying to cut one up, and then furiously ordered both to be put in his bag and he would take them back.

Boxing-day is a *dies non* in many businesses; and at Leadenhall Market, although every one is obliged to attend, it amounts to little. Salesmen and men are lounging about. Between eleven and twelve buyer, who is rather seedy and ill-tempered, goes into the Market. His temper is not improved as he walks up the passage. No solicitations to buy, but a great amount of "chaff" as to the contents of the bag. He is determined to face it, and seeing a curious bird suspended at a shop where four or five men were helping each other to do nothing, he boldly asks what they call it. A man touches his hat, and blandly says, "They do not call it at all, they fetch it when

they want it." This does not improve his temper. As he goes to the stall he is foaming. "Now, sir," says he, fumbling in his bag, "did you sell me two fowls Christmas-eve?" "Don't know," says the salesman. "Yes you do," shouts buyer, "and they were old ones. Look here!" and he produces one from the bag. "Well," says the salesman, "I think you are right—it is an old one." And just as buyer is about to talk about the "press," "imposition," and so on, he is told to be off and to take his rubbish with him, and finds himself the laughing-stock of every one.

ULVERSTON EXHIBITION OF POULTRY.

The annual Show at Ulverston is just concluded; and, although the number of pens exhibited this year is scarcely equal to those of former meetings, the general superiority of the birds competing was the subject of universal congratulation: the fact being, there was scarcely an indifferent pen to be found in the whole collection.

This Show possesses the great advantage of having a Committee of Management, all seeming to have one common interest in its welfare and perpetuity, every member proving himself ready and willing to put his shoulder to the wheel whenever necessity requires it. Here is an example that might be followed by not a few committees of similar exhibitions that we meet with year after year, to their several improvement and stability. A somewhat general failing in such committees is this—that although at the onset the proposition to institute a local poultry show is met by universal sanction and approval, yet, when the work ever consequent on carrying out such a meeting in a successful and orderly manner hangs heavily, the greater proportion prove themselves either actual deserters altogether, or hang about listlessly, causing even increased difficulties to the few who only desire to act with promptitude and efficiency. Not so at Ulverston. Every one of the Committee was at his post, all evidently anxious by his own personal efforts to insure the perfect success of the undertaking.

The Victoria Concert Room is another great advantage to this Society, being at once a spacious, well-lighted, and perfectly-ventilated exhibition-room. This year's Meeting, too, reaped an unlooked-for advantage; for last week a ball was held, and the whole building had been on that occasion most tastefully and profusely decorated with artificial flowers and evergreens, which, still remaining, added very materially to the general appearance of the Poultry Show without increasing either labour or expense to the Committee; the whole appearance of the Show was, therefore, singularly effective.

To say that the fowls were efficiently managed is only a recapitulation of our statements respecting former Shows at Ulverston. The Committee, being most of them poultry exhibitors, left nothing undone that could be done to insure the safety and well-being of every pen confided to their care; nor do we doubt that many birds will reach their respective owners in even improved condition to that in which they were forwarded.

In *Spanish*, Mr. Teebay, of Preston, took both the premiums, closely pressed, however, for the second position by the Hon. Secretary, Mr. Robinson, who exhibited a pen of birds of unusually good quality. It is really surprising how much the cock bird in Mr. Teebay's first-prize pen now assimilates to its parent, that for some years past was the most coveted of any among Spanish amateurs. The four hens exhibited from this yard too were four of the best-conditioned hens we ever remember to have seen together.

In *Dorkings*, the class generally was superior to common; but the first-prize Silver Greys were unusually perfect and well shown.

In class 3, for *Game*, Black-breasted or other Reds, the competition was most extraordinary, as the fact that only a single pen in the class remained unnoticed in the prize list will elicit. Mr. Robinson here exhibited the same cock as was shown at Whitehaven some fortnight back, and of which we then spoke so favourably, but with hens of infinitely better selection; they therefore now took precedence in a competition that rendered success even an increased difficulty. The Duckwings were good, particularly Mr. Hindson's first-prize pen, which were as perfect in condition as in plumage. In the second-prize pen we at once recognised an old acquaintance, although now the property of a fresh owner; he is still, as he always was, one of the best birds

in hand of Duckwings we ever met with, but is fast declining in the colour of his plumage; from this cause his triumphs as an exhibition bird are on the wane. The Black Game shown deserve our highest approval; but the Whites and Piles were not above mediocrity.

The *Cochin-China* class was really excellent, more particularly the Partridge-coloured variety.

All the four classes of *Hamburghs*, although very good, betrayed an almost general fault, to which we have repeatedly alluded as ever fatal to success—*viz.*, imperfect comb. We again say too much attention cannot be given to this point in selecting birds either for nesting or exhibition purposes.

The *Polands* only mustered three pens; but still all were capital. Black, Silver-spangled, and Golden-spangled were the varieties shown.

In the "Extra Class," Brahmas, Malays, and Black Hamburgs were especially good; the fact is, there could scarcely be better ones.

The Sobrigit *Bantams* were shown in first-rate condition, the competition being good throughout. The Game Bantams were undoubtedly one of the best varieties of poultry shown, whether as pens of three or single cocks. From some cause or other, however, not a few of the best birds were exhibited in very far inferior condition to ordinary.

In *Aylesbury Ducks* Mrs. Seamons took the lead; but more closely pressed than we ever yet remember by the second prize birds, belonging to Mr. Robinson, of Ulverston. A most unprecedented feature, and at the same time a most satisfactory one, occurred in the Rouen Duck class; throughout the whole rather extensive class only a single pen was faulty, either in bills or feather, consequently the scales were called upon as the surest talisman. Here again they proved closely competing, the best pen weighing 25½ lbs., and even the lightest weight among the whole was 22½ lbs. fully. In Buenos Ayres Ducks, Mr. Sainsbury, of Devizes, secured first position with a most excellent pen, in defiance of a very spirited competition among six pens (out of a class of eight), all standing well-named in the prize list. We must surely have been wrongly informed that this gentleman had determined to sell out, and abandon the fancy, for this cannot possibly be while in possession of such specimens as those shown at Ulverston. A beautiful pen of Mandarin Ducks, and a perfect trio of Call Ducks, were attractions in the extra Duck class.

We now come to a most important feature in the Show—the class for *Single Game Cocks*, the prizes being very liberal the competition was necessarily most cutting and severe. Thirteen birds are favourably mentioned in the prize sheet. As might be expected, condition here told a heavy tale, either pro or con, as the birds forming the whole class (save one) were tested by the hand. It is right here to name that a very capital bird (pen 168), willfully trimmed the night previously in the hackle, was at once disqualified, and this silly act of its owner prevented its competition, whilst otherwise it might have stood well placed. The excuse made by the proprietor, we confess a flimsy one, "he never thought the Judge would have detected it, or he would not have attempted the deception." The first-prize bird was a marvellously good Black-breasted Red, taking a £7 prize; the second, a peculiarly neat-looking bird for his enormous size (said to be 7½ lbs.), a Brown Red; the third, also, was the same colour; and the fourth, a Black-breasted one. Many of these birds only reaching a high commendation, had stood in far higher position at former shows; but now their condition was vastly deteriorated. As a class we rarely see better.

The following is the list of awards:—
SPANISH (Black).—First and Second, R. Teaboy, Fulwood, Preston. Highly Commended, G. Robinson, Highgate, Kendal.

DOBKINGS (any colour).—First, J. Rowlandson, Hawksheld, Lancashire. Second, J. Robinson, the Nook, Ulverston. Highly Commended, T. W. Hill, Manchester. Commended, W. W. Rutledge, Kendal; R. Sergeantson, Prescot.

GAME (Black-breasted and other Reds).—First, R. I. Robinson, the Nook, Ulverston. Second, G. C. Whitwell, Kendal. Highly Commended, N. Grimshaw, Burnley; E. Swainson, Newton-in-Cartmel; R. I. Robinson; J. Boulton, Ulverston.

GAME (Duckwings and other Greys and Blues).—First, J. Hinds n. Everton, Liverpool. Second, J. B. Chane, Coalbrookdale, Shropshire. Highly Commended, R. I. Robinson, the Nook, Ulverston; W. Dawson, Birmingham; W. Brocklebank, Ulverston. Commended, W. Brocklebank.

GAME (Whites and Piles).—First, R. Gelderd, Ulverston. Second, J. Martin, Newton-in-Cartmel. Highly Commended, E. Swainson, Newton-in-Cartmel.

GAME (any other variety).—First, W. Dawson, Birmingham. Second, M. J. Cranke, Criswick. Commended, G. C. Whitwell, Kendal; W. Charter, Driffield.

COCHIN-CHINA (any colour).—First, J. W. Walthew, Ormskirk (Partridge).

Second, W. Wood, Walkley, Sheffield (Bant Cochin). Commended, J. W. Walthew (Silver Cinnamon); E. Smith, Manchester. Second, J. W. Walthew (Golden-pencilled).—First, A. Nuttall, Manchester. Second, F. Hardy, Laister Dyke, Bradford. Highly Commended, J. Mann, Stacksteads, Manchester; Carter & Valiant, Poulton-le-Fylde; F. Hardy; J. B. Chane, Coalbrookdale, Shropshire; R. I. Robinson, the Nook, Ulverston.

HAMBURGH (Silver-pencilled).—First, J. Martin, Newton-in-Cartmel. Second, J. B. Chane, Coalbrookdale, Shropshire. Highly Commended, J. Dixon, North Park, Bradford.

HAMBURGH (Silver-spangled).—First, J. Dixon, North Park, Bradford. Second, H. Wilson, Crosshills, Yorkshire. Highly Commended, H. Baird, Kendal; R. Teaboy, Fulwood, Preston; J. B. Chane, Shropshire; G. R. Tate, Driffield. Commended, J. Phillips, Preston.

POLAND (any variety).—First, J. Dixon, North Park, Bradford (Silver-spangled). Second, H. Johnson, West Sunderland (Black). Highly Commended, J. Dixon (Gold-spangled).

ANY OTHER DISTINCT OR CROSS BREED.—First, R. Teaboy, Fulwood, Preston (Lancashire). Second, J. Dixon, North Park, Bradford. Highly Commended, J. Nelson, Dalton-in-Furness (Bahama Pouter); E. Hutton, Pudsey, Leeds (Black Hamburgs); T. W. Hill, Heywood, Manchester (Brahma Pouter); G. R. Tate, Driffield (Malays).

FASTAYS (Gold and Silver-laced).—First, T. H. D. Bayley, Biggleswade, Beds. Second, J. Martin, Newton-in-Cartmel. Highly Commended, I. G. Park, Gillhead, near Whitehaven; T. W. Hill, Heywood, Manchester.

BANTAMS (Game).—First, G. C. Whitwell, Kendal. Second, R. Moon, Jun., Wavertree, Liverpool. Highly Commended, J. Cragg, Kendal; T. H. D. Bayley, Biggleswade, Beds; J. Canna, Southwell, Notts; W. Silvester, Sheffield (Duckwings); R. I. Robinson, the Nook, Ulverston; E. Holdsworth, Cais, Leeds; G. R. Tate, Driffield; G. C. Whitwell; J. R. Roadard, Writington, Bristol. Commended, E. Yeardey, Sheffield (Duckwings); I. G. Park, Gillhead, near Whitehaven.

BANTAMS (any other variety).—First, Miss D. A. King, Whitehaven (Japanese). Second, E. Hutton, Pudsey, Leeds (White). Highly Commended, T. H. D. Bayley, Biggleswade, Beds (White); T. W. Hill, Heywood, Manchester (White Indian).

DUCKS (White Aylesbury).—First, Mrs. M. Seamons, Hartwell, Aylesbury. Second, R. I. Robinson, the Nook, Ulverston. Highly Commended, T. W. Hill, Heywood, Manchester; Mrs. M. Seamons.

DUCKS (Boucan).—First and Second, R. I. Robinson, the Nook, Ulverston. Highly Commended, W. Mitchell, Calverley Mills, Keighley; J. Dixon, North Park, Bradford; G. R. Tate, Driffield; R. I. Robinson; G. C. Whitwell, Kendal. Commended, R. I. Robinson.

DUCKS (Black East Indian).—First, G. S. Sainsbury, Rowde, Devizes. Second, J. Dixon, North Park, Bradford. Highly Commended, J. R. Jessop, Hull; E. W. Farle, Elenhurst, Prescot; H. Chitt, Jun., Birmingham; J. Martin, Newton-in-Cartmel.

DUCKS (any other variety).—First, J. Dixon, North Park, Bradford (Mandarin). Second, T. H. D. Bayley, Biggleswade, Beds. Commended, W. Charter, Driffield.

EXTRA PRIZES.

GAME COCKS.—First, J. S. Butler, Poulton-le-Fylde. Second, H. Parker, Wellington, Salop. Third, A. G. Brooke, St. Bees, Whitehaven. Fourth, J. Hindson, Everton, Liverpool. Highly Commended, E. Archer, Malvern; N. Grimshaw, Burnley; G. B. Kennedy, Ulverston; A. B. Dyas, Salop; Commended, E. B. Chane, Shropshire; J. Boulton, Ulverston; R. I. Robinson, the Nook, Ulverston.

GAME CHICKENS (any variety).—First, G. C. Whitwell, Kendal. Second, E. Archer, Malvern. Third, A. Hampson, Bolton-le-Moors. Highly Commended, T. W. Headcar. Commended, R. Parkinson, Poulton-le-Fylde; R. I. Robinson, the Nook, Ulverston; A. B. Dyas, Salop.

GAME BANTAM COCKS.—First, R. Moon, Jun., Wavertree, Liverpool. Second, T. H. D. Bayley, Biggleswade, Beds. Highly Commended, R. I. Robinson, the Nook, Ulverston; R. Moon, Jun.; J. Canna, Southwell, Notts. Commended, J. Cragg, Kendal; J. Shortrose, Newcastle-upon-Tyne.

Edward Hewitt, Esq., of Eden Cottage, Sparkbrook, officiated as Judge, and the Meeting was very well attended.

THE CAYUGA BLACK DUCK.

The variety of Duck to which this name has been applied is remarkable for the great weight it attains, and the fine quality of its flesh. Its origin is not positively known. We first saw it fourteen or fifteen years ago in Cayuga county, New York, where it has been bred in considerable numbers. In general appearance, except in being of larger size, it closely resembles the Ceylon or East India Duck which we have seen in Europe. It is larger on the average than the Aylesbury, and nearly or quite as large as the Rouen. J. R. Page, of Sennett, Cayuga county, New York, who has bred these Ducks many years, states that he has had them to weigh 16 lbs. per pair at six months old. About the 1st of December Mr. Page killed some, the weights of which were as follows:—Young drakes 8 lbs. each, dressed; a young Duck 7 lbs.; five yearling Ducks from 7 lbs. to 7½ lbs. each. Mr. Page observes that there is usually more or less white on the breast of these Ducks, but he thinks they could be bred perfectly black. They are unquestionably a very valuable variety. The quality of their flesh we know is excellent.—(*Boston Cultivator.*)

EARLY POLLEN-GATHERING.—I have this day (January 27th), seen the bees of several of my Ligurian stocks bringing in pollen

pretty freely. It is a rather singular coincidence that it was on the same day of the month last year, that I first observed pollen-gathering in my apiary.—A DEVONSHIRE BEE-KEEPER.

CANARIES AT THE CRYSTAL PALACE SHOW.

THE Exhibition of all kinds of birds showed a great advance on previous years both in number and quality, showing what can be done by careful breeding. The Norwich classes were very superior. In the Jouque class the colours resembled that of an orange, and their shape was good. In the Mealy class they were all that could be desired—in fact, the best ever as yet presented for competition. In the Belgian classes vast improvement was very discernible, and scarcely a bad bird among them. So different from former years, breeders having turned their attention to the true breed, and have discarded the long coarse-feathered bird so prevalent in former times. The Crested birds are still behind in shape, &c. The Lizards were very good, but especial attention should be paid to obtain the clear cap, which in some was broken. The classes of "London Jouque Fancies" were especially good, and deserve the highest commendation; and the difference in the shades of colour could only be discovered by taking them out of the cage and bringing them in close contact. The feathers were of a most brilliant gold colour, and the green almost black. The Mealy were also good. In the "Goldfinch Mule" class too much cannot be said in their favour, they were of themselves a show. There were two hybrids between the Goldfinch and Bullfinch, perfectly beautiful, showing the two distinct breeds, and most rare.

The Foreign birds were in endless variety and good condition. The Parrots and Parroquets were well represented.

There were also British songsters in first-rate appearance, being very clean and looking as if well cared for. A novelty appeared in the Bullfinch class of two Pied, black and white.

In the Magpie class there were two of dun colour in the place of black, and, strange to say, were found in the same nest with others of the usual colour.

The Show, in fact, was all that could be desired, and no amount of praise is too great for Mr. Houghton, under whose direction the whole arrangements are made.—T. MOORE.

TEMPERATURE OF BEE-HIVES IN WINTER— VENTILATION—LIGURIAN QUEENS.

I HAVE to thank Mr. Taylor for his decisive confirmation in your last Number of my views respecting the effect produced by ventilation in lowering the temperature of the interior of beehives during winter. I find on examining his table recording the temperature of ventilated hives, that the highest point reached during the month of January was 61° by hive No. 1; whilst in hives Nos. 2 and 3, which appear to be the only others in which thermometerical observations were registered during that month, the highest temperature was 50° and 60° respectively. The results of these observations vary so greatly from those recorded by Huber, that the mere difference in climate between Switzerland and England cannot be held sufficient to account for it. We must therefore, it appears to me, come to the conclusion that the real cause of this remarkable variation is to be found in the fact of Mr. Taylor's hives being well ventilated, whilst those of his illustrious predecessor had not the benefit of this comparatively modern practice in bee-keeping.

With the view of testing whether the above-mentioned is or is not the real cause of the discrepancy alluded to, I this morning (January 29th), between nine and ten o'clock, ascertained the temperature of the central part of the interior of four of my hives by the introduction of a small thermometer which I allowed to remain until all excitement had subsided. The following are the results:—

Hive No. 7	86°	Hive No. 16	86°
" 9	86°	" 22	59°

Hive No. 7 is the least populous of the four colonies experimented on; but I should state that brood is present in all. This experiment appears to confirm the accuracy of Huber's observations, and tends to prove the correctness of the views propounded by me in page 317—viz., that ventilating wooden hives during winter prevents the deposit of internal moisture by lowering the temperature of their interiors. Whether this diminished temperature may not, by delaying the season for

breeding, be itself nearly if not quite as great an evil as that which it is designed to remove may be deemed an open question, and one which experience alone can solve. If wooden hives could be rendered equal as nonconductors of heat to those made of straw (in which ventilation is generally unknown), the deposits of internal moisture might probably be either altogether avoided, or at any rate greatly diminished. It is with this view that I have tried lining a couple of my hives with rush matting; but this experiment is, as yet, too recent to warrant me in pronouncing an opinion upon it. So far as my present experience and observation extend, I fancy it will be found most advisable to ventilate wooden hives during the first part of winter—say until the month of January commences.

The following extract from a letter written from Staffordshire, dated the 22nd January, in which the subject is adverted to may not be without interest:—

"I have this season been trying the system of perfect ventilation since the beginning of November—i.e., the bungs have been taken out from the tops of the boxes, and the apertures covered with perforated zinc. A friend of mine, mentioned by W. Johnson in THE JOURNAL OF HORTICULTURE, treated his bees in this way with the greatest success, and had the earliest swarms in the neighbourhood, and the consumption of food was very much lessened. I am quite persuaded that no amount of cold experienced in this climate will injure bees thus exposed. I closed the aperture at the top of my Ligurians about a fortnight ago, as I thought the warm weather would induce the queen to lay.

"My two boxes of common bees are still quite open; and all my bees are very healthy. Although the Ligurians and swarm of black bees may be said to have subsisted entirely on loaf sugar and water since August, I see no symptom of dysentery which attacked them last year when fed on brown sugar and beer.

"I find the Ligurians much more alert and watchful than the black bees, especially at low temperatures. Are any of your original queens still alive?—B."

In answer to the concluding query, I may state that only one of my original Ligurian queens now survives. Two fell victims last summer to the attempt to lead off natural swarms—a task which the state of their wings quite unfitted them for accomplishing. One dropped close to her hive, and, being returned by me, was cast out dead next morning, having been slain by a young queen which had made her appearance from a royal cell that I had overlooked. The other probably fell at a greater distance among the grass, as I could not succeed in discovering her. The swarm in each case returned to the hive whence it had issued. This (as it turned out) fatal mutilation of the wings was caused by the pulling about which the unfortunate queens received from the black bees during the time they held them in durance, on their being first introduced, and before they were allowed to exercise their royal functions. It adds yet another element of uncertainty in addition to the very great risk which attends the introduction of Ligurian queens to stocks of common bees.—A DEVONSHIRE BEE-KEEPER.

VARIETIES.

BUTTER FREE FROM TURNIP TASTE.—For fifteen years I have practised the following plan; and not only have had butter without having the least taste of turnips, but superior in taste and colour to grass butter. Imprimis—The cows should not be fed with turnips an hour previous to either morning or evening milking; next, the milk should always be collected in crocks or other glazed earthenware material, and not in wood; these crocks, before and after being used, should be washed clean with scalding water and thoroughly dried. Previous to putting in the milk or cream, about half a pint of sweet buttermilk and about the size of a large pea of saltpetre should be first put in the crock; then let the warm milk be strained as usual down on it. The quantity of buttermilk above mentioned is sufficient for thirty quarts of new milk. I always keep my milk from six to eight days before churning, and it is then both thick and sour. By following these rules, I am sure that any of your subscribers who try them will find their beneficial effects.—AN OLD SUBSCRIBER'S WIFE.—(*Irish Farmer's Gazette.*)

OUR LETTER BOX.

BANBRS (T. H.).—How can we tell the average weight unless you specify the variety? Some varieties are pigmies and others giants. We know nothing about the neighbourhood you mention.

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last thirty-five years, the average highest and lowest temperatures of these days are 45.3° and 30.5° respectively. The greatest heat, 65°, occurred on the 11th in 1831; and the lowest cold, 0°, on the 13th in 1855. During the period 151 days were fine, and on 87 rain fell.

CYCLAMENS.

OSTS of fresh specimens of the different kinds of Cyclamens (of some the leaves only, and of others leaves and flowers), from all parts of the country, and from plants bought in London and in provincial nurseries, have been sent to me, all of which I intend drying and preserving for future reference; but the questions and the references which are required of me regarding them would fill a book

of many pages, and what to do about them is easy enough: but it is more easy to see how very different the thing when done shall be taken by different growers, for it seems a universal point with the collectors of very old and very rare plants to have adopted the errors of the race of botanists who made the mistake, and maintained it for the last three score and ten years, about the Ivy-leaved Cyclamen. But I rather suspect the mistake has been of older date still, and that it originated with Linnaeus himself in his "Species Plantarum;" for Miller, who took all the botanical definitions of Linnaeus as far as they went, for the unreformed early editions of his dictionary, quotes Linnaeus' "Species Plantarum, 181," in his description of the "Ivy-leaf Cyclamen" (foliis hastato-cordatis angulatis) and says it grows in Austria, Italy, and other parts of Europe, so will thrive in the open air in England, and is never hurt by the frost; also, that its flowers appear before the leaves, "rising immediately from the root," in August and September, and soon after the leaves come out and continue growing all the winter and spring, till May, when they begin to decay.

I have two fresh leaves of this very plant in water before me from a clergyman in the west of England, who has one of the best-named collections of rare plants, perhaps, in the kingdom. One leaf is that of the white Ivy-leaved kind, the other that of the red-flowering one, and the reverend gentleman says "these two flower in the autumn, the flowers come before the leaves, and the plants are beautiful objects all through the winter; mine are old plants and very large. I have four in a large bed, one at each corner. I send you a few seedlings of each," for which I am very much obliged. I want a few of last year's seedlings, and a few seeds of that or any season for the last ten years, of all the kinds of Cyclamens in cultivation; and I also want a plant of all the kinds, not including the Atkinsii race, from as many growers, and as widely apart as may be found, purely for the purpose of identity, and solely for the benefit of eager correspondents, who desire their collections to be properly named, free from doubt, if that is possible.

I have a large collection of gay Cyclamens, and I No. 46.—VOL. II., NEW SERIES.

want no sort of persicum, no coum, and none between the two—that is, as is just stated, none of the Atkinsii race, a race the most lovely of them all; but I am full of them, and none of them are wanted for what is desired of me. Now, this Ivy-leaved of this English amateur, of Miller's dictionary, and the foliis hastato-cordatis angulatis of the "Species Plantarum" of Linnaeus, is not, and cannot be, the true Ivy-leaved Cyclamen at all; and I must beg pardon of the representatives of Sir E. J. Smith and Don, and of Dr. Lindley, for saying they made the mistake about this plant, as I thought they did, but since then, from a prick of the conscience, I traced the mistake back to Linnaeus, and they only followed the trump card.

Clusius, an old French writer, had named a south-of-Italy plant, and called it the Ivy-leaved Cyclamen long before Linnaeus was born, and that plant is much more tender in constitution than persicum, and has never yet been found in Austria at all, nor in Italy on the north side of the Po, nor much north of Naples. It is confined to the south peninsula, and there, as in cultivation, never fails to bloom in the spring, and never in the autumn; therefore, Linnaeus was mistaken about the Ivy-leaved Cyclamen, which was followed by all our British botanists, and had to be rectified. A most amiable old Italian botanist, Tenore by name, and lately deceased, undertook that task, and did it well too; and it is as well that British amateurs, too, should revise the names in their collections. As to the botanists, they put their numbers and names in their dried specimens of the plants right long since.

What I principally want to make out with these Cyclamens is the difference the different authors fell into in their descriptions. Some of these differences are such as to cause one to suspect that an entire new leaf must be turned over in the matter of Cyclamens. You never heard of any one having succeeded in raising a hybrid Cyclamen, but Mr. Atkins, formerly well known as a respectable nurseryman at Northampton. What, then, would you say, if I could make it as clear to you as crystal that some one else, and a very different kind of person, or persons, had done the same before Mr. Atkins or myself was born? That is really my impression, and I am all but certain that Sweet's vernum Cyclamen, which was also known to and described by Miller, if not by Linnaeus, is a hybrid between coum and something of which I am not quite certain; but I think it is, or was, a cross between a late September bloomer, such as neapolitanum (the common English hederatifolium), and an early-blooming coum. I suggested the very same cross in this Journal long ago, but at that time I had no idea about the origin of vernum. But I have since received a true vernum, and I can see how it came into the world. If, indeed, any one can point out to me the exact spot where it may be seen or found in a wild state, then I would send a commissioner to that very spot before I could believe such a thing; and what makes me so certain, is the most remarkable deviation we see in this new race by Mr. Atkins.

I had ten specimens of verum sent to me by ten persons widely apart, within the last three years, and there is one now fresh before my eyes from the nursery of my early day's assistant in proving rare plants—Mr. Wheeler, of Warminster, not one of which is, or ever was, of the same race as verum; they all belonged to the *Atkinii* race. Indeed, from what I know of round London, I suspect the true verum *Cyclamen* is not on sale in any part of Great Britain.

I have a doubt upon my mind as to the true origin and history of Goldie's *Cyclamen ibiricum*. I never had that plant in my hands, and only know it from the figure; but I would have no great hesitation in booking it with verum; and unless the spot of its nativity can be pointed out to my commissioner, I shall have it down as a hybrid from *comum* by *persicum*, its origin being different from that of verum. What is the history or supposed history of *ibiricum*?

The flowers of the true *Cyclamen verum* are twice the size of those of *comum*, or about that in all the parts. The colour of the flowers is entirely different from those of *comum*; the colour is lilac, exactly as in the pale red common *Lilac* of the shrubbery, with a very dark large black mark at the eye, or at the bottom of the divisions of the flower, and when it is left to itself it blooms early in November, never later than the end of that month, unless the bulbs are dried off and are kept dry late in September. My plant has now bloomed three years running, twice before October was out, and last autumn just at the middle of the first week in November. I quite agree with Mr. Gordon, late of Chiswick, who grew it and recd. it from it in the Chiswick Garden, and who well described it in 1843, that it is entirely a misnamed plant, and that it ought to have been called the winter *Cyclamen*.

The three fresh varieties of *comum* now on my table are thus written of by the reverend gentleman who sent them. "No. 12 is, I believe, true *comum* with its plain round leaves. No. 13 I have as verum; but I cannot see much difference between it and No. 14, which is, I believe, a variety of *comum*." All quite right and no signs of a verum in No. 13; but what follows is what I want you to take heed to. "These three are now in beautiful flower, and are lovely objects. Their leaves come before the flowers, and they differ from the first two [white and red *neapolitanum*, *alias heterophyllum*] in this, that the flowers of the first two come in the centre of the plant [as in *persicum*] straight from the tuber, whereas these three last sent up their flowers outside the leaves, and so the flowers form an exquisite magenta margin to the rich green centre." This has never been so exactly or so truly recorded before this day. A magenta margin was worth living to see, and far more worth the little expense it would cost one to have it just now fresh from the nurseries on one's own table, or on a stand in the window of the drawing-room; but all the breed of *comum* require as much free air and as little confinement as a mountain *Daisy*.

But let me follow up the author and authority for the "magenta margin." He goes on to say, "Besides these, I have out of doors a small plant of *Cyclamen macrophyllum*—or whatever it may be called—and *Cyclamen europæum*, which was brought to me from the Alps; it is, however, a sickly plant, and I cannot say much about it." Every one who has communicated *Cyclamen* information for these pages through this channel has repeated the same circumstance—the bad or impaired health of his European *Cyclamen* through some cause or other. The *Cyclamen europæum* ought to have been called the summer or autumn flowering *comum*; for it is more like *comum* than like any other, but both its flowers and the leaves are smaller than those of *comum* when you have it true. The leaves of *comum* are quite entire on the margin, and quite free from marring; those of *europæum* are slightly toothed on the edge, and very strongly marked with the light marbling, which is peculiar to most of them. I can't find this *Cyclamen* anywhere, or procure even a leaf of it, and I have not seen it since 1835; but at that time and for the ten preceding years I never heard a word about badness of health, or any difficulty about growing it. But it must be a variable plant for Dr. Lindley figured it in the "Botanical Register" under the name *Clusii*, not long after Sw. et had it figured in his "British Flower Garden," 176, under the proper name *europæum*. That plant bloomed at the Exotic Nursery with Mr. Knight in August, 1825, and also the following year. Even as early as that period this kind was so much confused about London as *neapolitanum* is now; for Sweet expressly says, writing about *europæum*, that "the plant sold in British nurseries is nothing else than the British *heterophyllum*,

of which there are several varieties in the form of their leaves; it also varies with white and flesh-coloured flowers." From this description we see that Sweet, like all the rest of the British authorities of that day, was led away by the error of Linnaeus in overlooking the plant named *heterophyllum* by Clusius. But Sweet was right enough in his estimate of the fragrance of *Cyclamen europæum*; for he says, "The fragrance exceeds almost that of any other plant with which we are acquainted." And Dr. Lindley endorses the same opinion of its fragrance under a different name by mistake—that of *Cyclamen Clusii*, which he said "emits so delicious an odour, that no plant can be better calculated for ornamenting a lady's boudoir;" which was wrong at both ends, and only right in the middle; however, as the plant was this, our *europæum*, the first end; and the last plant in cultivation, not "calculated," but well known, to do any good at all in a lady's boudoir in August, the other end; but the sweet smell from the flowers is the next best thing in the family to magenta margin.

A plant which had puzzled so many, and which so few can report on now in a healthy state, I want to have, to see which was which, and which is so, if it be such, to the present day. Miller mentions a spring-flowering *Cyclamen* which is lost, if it be not the *ibiricum* of Goldie (*rubric. iniquale foliis orbatis*). The leaves of my figure of *ibiricum* are not orbicular, however; and whether the "root" be irregular or not is more than I can know, but Miller says "the root is not bigger than a nutmeg, the leaves small, the flowers in the spring only, and of a flesh colour, with purple bottoms," but rarely produced seeds in England. Can you tell what it is or might have been? Miller was well acquainted with that *Cyclamen verum*, which no one now-a-days seems ever to have seen. It was a late autumnal bloomer with him. "The leaves and flowers of this come up from the root at the same time; the flowers are of a purplish colour, and their bottoms are of a deep red; it flowers late in the autumn, and requires protection from the frost in winter." But there was no regular system of specific names in the time he first published, and his specific name for verum sounds odd enough in our day: it is this—"Round-leaved Sowbread, with a purple under side," which would apply to *comum* as well; but of *comum* he says, "Winter *Cyclamen* with orbicular leaves, red on the under side," also "the *comum* of the herbalists."

As the best remedy for sickly *Cyclamens* and for purposes new to you, I shall give another extract from the author of the magenta margin. When referring to his sickly *europæum*, he says, "But I shall give it a dose of cocca nut—my remedy for everything, and perhaps it may do better another year. That cocca nut is wonderful stuff. For pot bulbs I use it pure, and I wish you could see a large pot of *Veronica* that I now have; and in *Orchids* and other such things are looking most promising. I find it very good for potting *Geraniums* and other such things for keeping through the winter, and anything grown in it may be transplanted with half the usual trouble and risk, as the roots are not torn in transplanting. By help of it I have succeeded in growing healthy plants of the Parsley Fern—a regular teazer to most growers, cut of doors for more than two years."

This cocca nut stuff is more than a hundred miles from his garden; but my garden, in which everything under the sun would now grow, is made up with it and black sand, with a little clay to the depth of 4 feet, the first 20 inches being fully cut-third cocca nut sawdust, or rather crusher dust, and I winter all pots in which it is used should be plunged to the rim, as the dry sides of a pot in the sun or on the stages of a greenhouse will suck it dry faster than a ball of coppo-t, although a barrowload of it if placed in a round heap on the pavement would not get dry through and through for the six summer months. It was from this tendency in cocca nut fibre refuse that I had to double so many pots in summer, and hit upon stopping the ventilation between the tops of the two pots, and so founded the fact that moist bottom heat could be had outside the window the whole summer without any cost, but with a great deal of pleasure at finding plants, and no plants were ever yet found in such places, and now I have taken to it as a regular plan the year through. But for Ferns and bulbs I have been, from the beginning, indebted to the practice of the author of the magenta margin, to whom I mean to recommend the first magenta bed with a pure margin next week if all is well, and that I am not pushed off to some other colour.

A FEW DAYS IN IRELAND.—No. 13.

(Continued from page 374.)

TRINITY COLLEGE GARDENS, DUBLIN.

"SURE, and have you not been looking at the gardens, and with all your eyes too? it's to be joking me you are, sir!" was all the answer to a very polite inquiry we could obtain from a rosy-checked lad, who scampered off in high glee, no doubt imagining he had taken the conceit out of one who was merely asking for asking's sake; for to their honour, be it said, we never met with more courteous attention to all such inquiries than from men and women in Ireland. We received the above answer on our first morning in Dublin, after going all round the outside of the College, and looking through the railings at the men cutting the long grass in what is called College Park; and after we had come to the conclusion that the garden so long associated with the honoured name of Dr. Mackay, and more latterly with that of Mr. Bain, must be somewhere else than in the immediate neighbourhood of the College. We found next day that these gardens were south-east the best part of two miles, and the road to them passing through streets and squares, with the sides planted with trees in the Boulevard style, the property and the doings, so far as we recollect, of the late lamented and much-loved Lord Herbert of Lea. We felt it to be a great honour, after meeting with Mr. Bain, to be introduced to and to partake of the hospitality of the venerable Doctor, who is yet hale and hearty, and with whose name we had been familiar for the best part of thirty years.

As far as we recollect the Doctor retired from the curatorship in 1855. The Council of the College, to whom the gardens exclusively belong, honouring themselves in the honour and attention they bestowed on an old faithful servant, Mr. Bain then entered upon the duties of Curator; and of the propriety of that appointment, perhaps the highest authority stated at the time that "a better selection could not have been made." Mr. Bain, in addition to other spheres of improvement, had also been a favourite pupil of Dr. Mackay's. This may somewhat account for the complete and general confidence, and the strong reciprocal attachment existing between them, which even a stranger could not fail to notice at a glance. We are sorry to say that we have met with somewhat similar cases, in which there was anything but the same sweet accord. Standing up for the rights and fair fame of our order, it must be confessed, nevertheless, that there is one weakness among gardeners that is too generally developed, though there are noble exceptions, and that is the unmanly and the unseemly habit of depreciating the doings of predecessors. Bad enough in any case, it reaches the height of painfulness when that predecessor is advanced in life, and is passing the remainder of his days near the scene of his former labours. Few things would hurt the feelings of an old gardener more than getting the cold shoulder from a young successor. How much better to exhibit something of a filial and paternal regard! The younger will almost be certain to be the greatest gainer, there ever being an advantage in having the energy of youth balanced with the experience of age. The inflicting of a single sorrow may well cause a pang of remorse; there never will be a tear of regret because we had it in our power to cause the eye of any, and especially of the aged, to sparkle with joy.

A slight inspection of these gardens, which we all we could give, convinced us that objects of purely botanical interest were deemed of chief importance. This is just as it should be. If botanic gardens descend to humour too much the prevailing tastes of the day, their distinctive features and objects are apt to be lost. It would be well, if in the present rage for bedding plants, &c., young men should have access to such gardens as this, and get an idea of the importance of systematic and physiological botany. Insensibly we began to feel the importance of forgotten and neglected studies, and to our mortification soon found that we could keep company for so little way with Mr. Bain, who seemed to be as thoroughly at home in the recondite phenomena that take place within the spore-case of a Fern so as to insure fertilisation or hybridisation, as our friend Mr. Beaton is thoroughly conversant with the mode of insuring giant or pigmy Pelargoniums at will.

Instead of anything like a regular description we will merely notice a few things that chiefly arrested our attention.

First. The walks were commodious, and in excellent condition. The rains had fallen heavily that morning, but the paths were

firm, clean, and easy for the feet. If you put clay sticking to your feet out of the question, hardly anything else is more unpleasant to walk upon than shingly gravel, in which your feet sink, or which keeps rolling and moving with you as you go. Many a splendid garden has left an unfavourable impression on the mind because the walks were dirty, rough, or uncomfortable.

Second. The walls were well covered with a general collection of half-hardy plants, and some which require a greenhouse in general north of London. Along with such plants as *Glycines*, *Escallonia*, *Evergreen* and *Trumpet Honeyuckles*, *Roses*, *Jasmines*, *Clematis*, especially all the tenderer kinds, *Magnolias*, fine plants, &c., we noticed large plants of the *Ipomoea jalapa* in bloom; a very fine specimen of *Erberis fascicularis* covering a large space of wall; and good plants of *B. Darwini*, *Wallichiana*, *Bealii*, *Fortunii*, *japonica*, *dealbata*, *microphylla*, &c.; *Tecoma* of sorts; a nice plant of *Schinus dependens* (?) resembling *Mullii*, with fine graceful foliage; some fine plants of *Edwardias*, as *grandiflora*, *microph. la.*, &c.; almost every species and variety of *Ceanothus*, the *azures*, when true, still bearing the bell for beauty; good plants of two or three kinds of *Coletia*, *spinosa* being generally found the hardiest of these Chilean and Peruvian plants; several good plants of *Pistacia*, as the *Terbinth* and *Mastik-trees*; *Rhus trifoliata*; and a goodly number of Australian and Cape plants, either getting established or getting a fair trial as to their hardiness in such a climate. Instead, however, of mentioning plants generally found on such walls in England before the frosts of last year, it may be more useful to mention a practice adopted here with all plants against walls that are considered in the least tender—namely, several of the lower shoots are layered in the border pretty close to the foot of the wall, and these are easily protected in severe weather; whilst those against the wall are left to live or die.

Third. The trees and shrubs on the lawn are, in general, compact, dense masses, and are interesting not only on that account, but also from the treatment they have received to make them so. Among fine specimens of different coloured, and crisped, and plain-leaved *Hollies*, there is a fine specimen of *Hodgkin's Holly*, a fine, plain-leaved kind, that we do not recollect seeing before. It was well stored with berries, which are rather scarce things this season. The various kinds of *Arbutus*, as *andrace*, *hybrida*, *procera*, &c. Several varieties of *Alaternus*, *Laurestinus*, *Portugal Laurel*, *Rhododendrons*, &c., were close and compact masses of growth. Among the Pine tribe we noticed good young plants of *Wellingtonia*, dense specimens of *Thuja*, *Cupressus*, *Juniperus*, and masses rather than plants of *Cryptomeria*, *Taxodium sempervirens*, &c.; also, nice plants of *Picea nobilis*, *Nordmanniana*, and fine specimens of the frer-growing *Pinuses*, as *austriaca*, *palustris*, *Pallasiana*, &c. Some specimens of *Pinus excelsa* were extra interesting, not so much for their height, though that might be from 20 feet to 30 feet, as from the density of growth, and the great width of the branches at the base, much more than the height of the plant, sweeping over and covering the grass like a dense bed. Mr. Bain has partly promised to give us the dimensions, width of diameter of branches, as well as height of tree of some of the best of these specimens. In the case of these fine *excelsas*, we understood that little or nothing had been done to produce such a striking effect, but most of the other dense specimens had been carefully treated to produce the desired result. A dense habit of growth being desirable to resist the violent gales from the south-east, and the trees and shrubs naturally being inclined to grow rather open and thin.

To neutralise this, evergreen shrubs and trees had been treated in different ways, when the branches get thin and scraggy. In some cases they were pruned severely back, so as to produce new and healthy shoots, which were carefully shortened when young, &c. In other cases, the lead of the shrub was bent down to the ground, and the young branches layered, and when they grew vigorously it mattered little what became of the old plant. The layering system had also been adopted with the whole of the Pine tribe, including *Cryptomeria*, *Thuja*, &c., and the effect in producing dense masses was very striking. Young plants are treated much the same as hard-wooded evergreens. Older plants of the resinous tribe, that are getting thin and unhealthy, have only the lower branches layered, and these soon form dense, healthy masses. Healthy plants, but getting thinner and opener in growth than is desirable, have only the lower branches pinned or tied down to a more horizontal position, and that generally induces a denser habit.

Layering is, however, never resorted to, in the case of a healthy, fine-habited plant, unless for increase of stock, as in every case it robs the original stem of its vigour. Its effect in changing an unhealthy specimen into a vigorous, dense mass, that on passing you would not know from a single plant, is very striking. In layering, the bark is merely pared off, the wood is not touched at all, no slitting, tonguing, or anything of the sort. Perhaps the moist climate may have a little to do with the success.

A similar mode is adopted with valuable but leggy and unhealthy greenhouse and stove plants, and thus by bending and layering the shoots of the head, fine masses and finer individual plants are obtained much sooner than by striking and growing in the usual way. Some of the tenderer shy-flowering Rhododendrons have been induced to bloom freely by bending down the shoots and tying them in a recumbent position, the sun had so much more power in concentrating the juices, that flower-buds were formed on the points of the shoots thus reversed. Sufficient vigour was in such cases secured in the ordinary way. We saw some fine specimens of Edgeworthii, &c., thus treated. We did not notice the thing ourselves, but a friend told us afterwards, that by the old system of ringing the *Draecena draco* was induced to bloom some three years ago, and by a deepish incision into the stem of the Sabal Palm, that strong-growing variety was made to fruit when of a moderate size.

Fourth. Leaving all notice of herbaceous plants in beds and borders, we would just state, that in a shady place near a wall is a full collection of British and Irish Ferns. Among these we noticed a fine specimen of a Lady Fern, from the county of Mayo, partaking of the properties of *crinata*, *multilindum*, and others. The most striking thing, however, in that way, was the variety of the Lady Fern, called *Frizeliae*, found by a lady of that name in the county of Wicklow. Some of the fronds come like the common Lady Fern, and others come long but furnished with pinnae at rather open intervals, resembling in appearance those of *Pteris rotundifolia*. In plants in pots in-doors, there was considerable variety as to the extent of the different forms, but all had these forms less or more, and in some cases there was hardly a trace of the true *filix-femina*. As far as we recollect, Mr. Bain has raised plants from spore-seeds, and also by striking the round-fronded pinnae, and the plants presented very much the same appearance of those obtained from dividing the roots, with the exception of the new form being rather more abundant and constant. This form may, therefore, be considered distinct and lasting.

PINE APPLE CULTURE.

(Continued from page 232.)

WATERING, SYRINGING, AND ATMOSPHERIC MOISTURE.

The cultivator having procured and provided a good soil for his Pines, he should next provide a supply of good water. Every writer on this point, myself amongst the rest, recommends rain water as the best to water all plants with, whether in pots or in beds of earth. Perhaps some reader may inquire why this kind of water is better than pump or pond water. The reason is because pump water is generally hard—that is, feels hard to the skin when washing in it and curdling soap. This hardness is caused by its containing an excess of salts of lime or magnesia, which is poisonous to plants. Stagnant pond water contains in excess carbonated hydrogen and other gases equally, if not more, injurious to plants. If, however, hard water must be used, the injurious properties would be counteracted by putting in amongst the water about a quart of ammoniacal liquor from the gas manufactories to every hundred gallons a few hours before it is used. River water approaches the nearest to rain water in goodness for watering purposes. Rain water, on the other hand, contains rather more than 4 inches of air or gas, half of which is carbonic acid gas, and the remainder consists of sixty parts of nitrogen and forty of oxygen gas—all highly beneficial to vegetation. Every observing cultivator must have noted how much better his plants, whether in pots or borders, thrive when rain falls than they do from water applied from the garden-pot in dry weather, however bountifully he may supply that necessary liquid. This well-known superiority of rain water makes it desirable to preserve it for watering purposes, especially for plants under glass. Not a drop of it should

be wasted. To keep it in quantity tanks sunk in the ground are the cheapest of reservoirs. These may be made water-tight by puddling with clay well-tempered, or by a coating of the best cement. All the rain water that falls on the buildings in the garden should be caught in gutters and conveyed by spouts to the tanks. If possible, a good large cistern should be placed inside the Pine-stove, or in a warm shed behind, from which it may be conveyed by a pipe to a tap inside. From such a cistern so placed, the water will always be warm enough to give to the plants. Should there be a long succession of dry weather then the water from the tanks should be pumped up and conveyed into the cistern to be warmed. If there is no cistern it will be necessary to have some water made hot and mixed with the cold to warm it. The water should always be used at a temperature of about 80° in summer and 60° in winter. The maximum quantity of water should be given when the plants are growing freely; enough should then be applied to thoroughly wet the soil in the pots, or when the plants are planted out enough should be given to moisten well all the soil in the bed. This to be repeated, as the soil dries either by evaporation or by being taken up by the plants. The minimum quantity would be given during the short days of winter; the plants will then be in a rather dormant state and require but little water. It is not wisdom to give a measured quantity at any time of the year. In bright, clear, sunny weather more will be needful; and *vice versa*, in wet dull weather less will be required. In that respect much must be left to the discretion of the manager. When fruit is swelling also water freely; but when changing colour for ripening withhold it altogether; or the flavour will be injured. Also just after rotting no water will be necessary till root action recommences. Should bright sunshine occur just at that time, to prevent the plants flagging it will be better to shade the plants during the middle of the day than giving water. The cultivator should always remember that the Pine Apple is a succulent plant, the roots of which are easily destroyed by excessive moisture in the soil. In winter, should any water lodge in the hearts of the plants, whether from the watering-pot or from a drip from the roof, it should be instantly removed; for this purpose I have used a long tin tube, and drawn the water out by suction with my mouth. If it is allowed to remain any time the plant containing it will certainly rot off.

WATERING WITH LIQUID MANURE.—The size of the fruit, especially of the larger-growing kinds, may be greatly increased by watering the plants with liquid manure. This should not be given until the fruit is visible in the heart of the plant, because if the plants have been grown in the compost I have described, or one approaching to it, and well managed in other respects, the plants will have grown sufficiently large and strong to produce large fruit, and if too much nutriment is given to them they probably will continue growing almost indefinitely: therefore withhold the liquid manure until the fruit is discernible, then water every third time with this enriched water. When I grew the large Providence Pines I made my liquid manure of the following ingredients—pigeons' and fowls' dung. I got all I could of this, and filled a large tub one-third full; then I put in about half a peck of quicklime and as much soot. On these I poured boiling water till the tub was nearly full, and stirred the whole up well together. The lime and hot water effectually destroyed all insects, and their eggs also, and the soot and lime killed any worms that were in the pots containing the Pine plants. I allowed this mixture to settle and cool down to 80° previously to using it. With this liquid manure and the compost together I was enabled to produce very fine fruit. As an instance I may mention that one morning I cut five Providence Pines, that, altogether, weighed 15 lbs. from five three-year-old plants. They were of the variety named the New White Providence.

SYRINGING.—The syringe should be in requisition during the fast-growing season, which may be said to commence in March and end in September. In the earlier and latter part of this season syringe gently in the morning, and during the summer months in the evening also, omitting, of course, to syringe in very wet weather. Always syringe with warmed water. Observe, however, not to syringe plants in fruit when the fruit is ripening.

TO PROCURE ATMOSPHERIC MOISTURE.—Syringe the hot-water pipes and flues during the growing season in the earlier and later months morning and evening, and in hot summer weather three times a-day. It is a good plan to have troughs on the hot-water pipes and dish-covers on flues, and to keep such hollows full of water during the growing-months—that is, from March to September. This moisture in the air is of great

service to the plants; it keeps them growing kindly and freely, and is a great preventive of the increase of insects.

AIR.—A very general direction might serve for giving air—namely, give air every day not actually frosty. But that wholesale instruction, though it is quite sufficient for an experienced cultivator and manager of hothouses, is hardly explicit enough for a young beginner.

Through the months of *November, December, and January*, give air only for two hours daily—that is, from eleven to one, unless a very sunny day or two occur, then the air may remain on longer; on the other hand, should wintry weather occur, such as heavy snow, or rain, or very severe frost, then keep the Pine-stoves closed up till the weather changes.

February, March, and April.—Increase the quantity of fresh air as the days lengthen, more especially towards the middle of March and through April. Frequently we have fine warm sunny spring days, then give air by 9 o'clock A.M., and continue it on till 3 P.M.; but in cold weather give air accordingly, shutting up earlier, and filling the stove with steam.

May, June, July, and August.—The weather through these four summer months is more settled, and, therefore, more air may be given—indeed, through the two last-named months a little air may be left on all night.

September and October.—These two months complete the year. The air given should be reduced gradually, so as finally to assimilate with the quantity as directed for the winter months.

The object of giving air is not only to reduce the temperature of the house; but also to let out foul air, and let in fresh pure air, which invigorates and strengthens the plants, and gives a greater amount of flavour to the fruit. T. APPLEBY.

(To be continued.)

ICE-HOUSES VERSUS ICE-STACKS.

THE late frosty weather seems to have set us all by the ears on the subject of ice-preserving; and assuredly in the multitude of councillors there must be safety, and I congratulate myself on my view being so ably backed by Mr. Thompson, at page 355; Mr. Fish also coincides with some of my ideas. On the other hand, I am equally thankful to Mr. Beaton for putting me right in my chronology regarding "London's Magazine," which might not have started into life until 1826, instead of 1824, as stated by me; but certainly some of the Numbers of that periodical did treat on subjects connected with ice-keeping. Applying hot water to the broken ice at the time of ramming it down in the ice-house was assuredly recommended by one writer to that useful Magazine; but I have not the volume by me, and must therefore only argue on memory.

This, however, does not affect the case in hand, for I did not assert that the plan of stacking ice in the open air was discussed in the gardening papers at that time, but that there were practical experiments made that way, as I was acquainted with a place on the boundaries of Cumberland, where an ice-stack was made on the north side of a steep hill, and sheltered, or rather shaded by trees, in the winter of 1828-29, and I was told that the season I speak of was not the first one that ice had been so stored away, and kept pretty well. I believe the heap was supported at the sides by posts and fagots, or something of that sort, and the top covered over thickly with fern, which abounded in the neighbourhood. I, however, only guess at the latter part as being likely; the fact of there being an ice-heap at the time spoken of I am more positive of, an intimate friend of mine having assisted to make it. Enough, however, has been said on this head, and no one is more grateful than I am at such excellent suggestions as those made by Mr. Earley, of Digsweil, page 335, and I believe his observations can be confirmed by several, whom I hope to see communicate their views or experience in the pages of THE JOURNAL OF HORTICULTURE; and as the new-fashioned ice-stack seems to have no lack of supporters, I will endeavour in some measure to defend the cause of the old-fashioned and much-abused ice-house, and will even take it with all its faults, non-ventilated and all, as being the most convenient, economical, and best place to keep ice in, that has yet been discovered. In taking this general view of the question, it is not fair to take an isolated case of an extreme character; but let every one speak fairly and candidly, and if I leave the discussion of the last of the three qualifications alluded to, "that of being the best place to keep ice in," to be decided

by other contributors, I will endeavour to combat the views of the ice-stacking party on their own grounds, which I believe they affirm to be convenience and economy. Let us therefore see how far their contrivances justify their terms, or whether they may not be both linked on the side of the poor old ice-house. Beginning therefore with the first of these—

Convenience.—As local circumstances will have determined the site of the ice-stack, it will most likely be found in just such a position as the ice-house ought to occupy: therefore, as far as the carting and storing away of the article are concerned, both the contrivances may be on a par. It is therefore only on the subject of obtaining the ice when wanted, that it is necessary to make the comparison, and assuredly the merit lies entirely on the side of the ice-house. Opening a door, or perhaps two or more doors, and stepping upon the naked ice, is an operation much quicker and easier performed, than removing a large quantity of straw and other litter, and replacing it again, when a barrowload of ice is wanted; and it sometimes happening that some article particularly wanted to be preserved can be done so in an ice-house, which cannot be done in an ice-stack, I believe the greatest advocates of the latter will admit the merit of "convenience" to be on the side of the ice-house. I will now venture on the vaunted ground of economy, on which they base their claim to superiority, and see if I cannot prove that a false impression has not gone abroad on that subject. Leaving, therefore, the item convenience, let us take up the much more important one of

Economy.—On this head I will as an example take our worthy correspondent Mr. Earley's plan, which Mr. Beaton lauds so much, and which I by no means find fault with; and as the readers of THE JOURNAL OF HORTICULTURE will have perused his clear and well-defined mode of operation, I need not repeat it here, further than by saying that, as I understand him to say, a wall of straw 2 feet thick surrounds his ice, and a top thatching of quite that thickness also, and I believe an outer thatching of the sides is also included; the straw forming the walls being the best wheaten straw, and trodden firmly down between the two hurdles forming the inner and outer framework of the wall. Now, as all arguments on economy ought to be settled by figures, let us see how straw and bricks can be compared together, and I may say that here a load of straw comprising thirty-six trusses of 36 lbs. each costs quite as much as one thousand bricks; and, in most localities where bricks are made within fifty miles of London, the comparison is about alike. I may also add without going into exact calculations, that five thousand bricks would build an ice-house capable of holding sixty loads of ice or more; and, when once built, its durability may be estimated by hundreds of years; for, unless some unusual convulsion of nature occur, it is difficult to say how many centuries an ice-house, or rather the stone or brickwork of it, will last. Contrast this with the hurdle and straw casing of the ice, and we shall find that the straw alone for the wall and covering of the ice-stack will cost as much in one year as the bricks do that build the ice-house; besides straw will only last one year, and a covering on all sides rammed down, and 2 feet thick, would require quite five loads of straw, and this to be removed every year. It is, however, only fair to say that the other items of expenditure in the ice-house exceed that of the ice-stack; but, as assuming the expense of digging an ice-well, putting in a drain, erecting the structure and putting on the doors—in fact, doing everything to it that was wanted, cost three or four times the cost of a temporary erection and covering for an ice-stack, is a yearly expenditure of one-fourth of what would procure a permanent structure a judicious and economical affair? Most certainly not. And according to the recommendation furnished us by Mr. Earley and Mr. Beaton, the expense must be quite as much as I say, and all the other operations of filling, &c., are on the whole more expensive in the ice-stack than in the house;—where, then, lies the "so-called economy?"

Much has been said about damp destroying ice, but I feel certain a strong current of mild warm air wastes it more. In the middle of January last we had a sharp frost from the 16th to the 22nd, the ice at the latter end of it being 2½ inches thick, or more; and an ornamental basin in our garden being that thickness of ice I took a part of it off in large pieces, some of the pieces were laid flat on the ground, and some raised on edge, or rather propped up from the ground. The first day's thaw was mild and moist, the next day was a brisk wind, and as Mr. Thompson justly observes, it very quickly licked up all the ice which was exposed on all sides to its action, while that lying

flat on the ground lasted longer, and that in the water longest of all. Reasoning from that, I, therefore, cannot see in what way a dry current of air over ice can do other than waste unless the temperature of that current was under 35°; for, assuming it to be dry, and about 50°, it would simply withdraw moisture from the ice the same as an east wind or very dry air withdraws water from our ponds, plants, and even our lips. And sucking moisture from ice is exhausting it of its very life-blood, that I confess I cannot see on what grounds the advocates for ventilation can found their plea upon; for I confess being unable to account for its wasting by any other agent than heat, and cannot but think a dry atmosphere of 55° quite as likely to waste ice as a humid one of the same temperature, as the latter being already charged with moisture is not likely to rob the ice to the extent the other would. I am, however, far from assuming this to be absolutely the case, but I believe it to be so; and, again, I am sorry to differ from Mr. Beaton, who in a late communication makes a damp atmosphere waste ice seventy times as fast as a dry one, by which I take him to mean that a quantity of ice that would keep one day in a damp air would keep seventy days in a dry one. None of my ideas approach anything like this, as I confess there are few ideas, contrivances, or inventions, that can be reasonably said to exceed those previously existing in more than a twofold degree; and in the matter of ice-keeping I have yet to learn that our grandfathers' maxims of excluding all air from it as much as possible was wrong, as I have seen no artificial rule which proves so; and certainly all natural law as previously explained by Mr. Thompson and myself in a former article, tends to prove that currents of warm air waste ice and snow faster than anything. More, therefore, need not be said, although collateral evidence bearing that way is far from being exhausted. I would rather, however, have the practical statements of others.

J. ROBSON.

AN EFFECTIVE WASH FOR OLD WALLS INFESTED WITH WOODLICE.

YOUR remedy given in page 353 is sound enough, but rather troublesome. Your correspondent "WOLCESTER" should un-nail his trees; take 4 lbs. of soft soap to the gallon of soft water, well mixed, and apply it with a new painter's brush, filling every crack and crevice with it. A cheaper and equally or more thorough insect and insect-egg killer is 1 lb. of Gishurst Compound to the gallon of soft water applied in the same way. These mixtures are most killing to the whole tribe of insects. The Gishurst Compound is one-third cheaper than soft soap used in the above proportions; and, if the wall is thoroughly dressed, by inserting the brush well saturated with it into every crevice it will effectually prevent woodlice from sheltering themselves in them all through the summer.—AN OLD GARDENER.

THE CAMELLIA AND ITS CULTURE.—No. 3.

A VERY opportune time for *repotting* general stock is during their season of rest. When, it may be asked, do you fix that period? Immediately after they have done flowering, and from four to eight weeks thereafter, according to the particular period they are in bloom. For instance, plants that have done flowering before the "turn of the day" can have two clear months of comparative sluggish action,—for so long as a plant is in life, be it deciduous or evergreen, there is always a circulation of the juices distending, enlarging, and solidifying the plant—certainly at the so-called season of rest in an infinitesimal degree, and the beautiful piece of anatomical mechanism only thrown out of gear when the sap or life-blood is frozen, before it is necessary or even wise to call forth all their physical energies into play; while those that are retarded until March and April by the force of circumstances, the length of the day, and the greater amount of warmth and solar radiation as the sequence, push away without, and point out that now is the time for the addition of artificial heat.

In all large collections there is not much difficulty in having flowers from nine to ten months in the year if such were in demand; albeit, it requires both time and skill on the part of the cultivator to attain this. Of course you will have but a small sprinkling to begin with, gradually getting larger and larger, and waning out towards the end of the season in like proportions. Here we very often begin with Lady Hume's

Blush, and the Old White early in September and finish up the season in the first week of June with Beali, or Leana Superba, and occasionally Princess Baechiuchi. But we require to retard in the one instance and accelerate bud-formation in the other—the former by far the more difficult task of the two. Those who merely read over the matter out of pure love for, shall we say?—the charming queen of winter—who have little knowledge of practical details, and who may be inclined to pay homage to my idea, may possibly exclaim, "Oh! I see; if they are wanted early they can be put into strong heat; and if late, retarded in a cool greenhouse." I beg in return to say there is no more stubborn subject in the whole plant community to force than a Camellia bud on grouse-shooting day. The fact is, from the time the buds are properly formed they should be, approximately speaking, comparatively at rest, else nothing but failure, either in the flowers when expanding being forced and abortive, or the buds dropping off altogether, will be the result. But more upon this point when we come to discuss a subsequent division of our subject.

To return to repotting. We say there is not a better time for the operation than during the probationary period of their season of rest. They can be thoroughly examined, cutting away any decayed rootlets, picking out any sodden mass which the roots may have turned away from in disgust. For we are of opinion, backed up by experience, the roots have the power of selecting nutrient best suited to their wants, if within their reach; if not, it incapacitates their formation. And shaking out worms and worm-casts, they may either be liberally shifted or otherwise, according to the wants and accommodation of the parties concerned. If they are liberally shifted in the compost already treated of, there will be less demands for water and none at all for manure water for some time to come. If, on the contrary, they are wanted to produce a given quantity of bloom in as small growing space as possible, they can be reduced and repotted into pots of the same size with fresh compost; and as soon as the pot is full of roots, liquid manure or guano water, which if applied cautiously is a good and safe stimulant, may be administered. It is really astonishing, even to the practical man, what a yield of bloom may be produced from a plant in a small-sized pot. It was only the other day that I met a few gardeners in the great commercial city of the west of Scotland; and as usual at these fortuitous occurrences, some one or more points of gardening do turn up and are generally very pointedly introduced and discussed, for "in the multitude of councillors there is safety." "I have grown Camellias," says a gentleman, who has for the last three years retired into private life with a handsome pension awarded him by his employers, "for the last five and thirty years, and I am sensibly impressed that too much shifting defeats rather than furthers your purpose—as an instance of which, I had a plant growing in a six-inch pot from Mr. —, pointing to a gentleman across the table, which he had not shifted for ten years previously, and I grew it fifteen years afterwards in the same pot without so much as examining it, and it flowered year after year to my satisfaction, and" somewhat warmly, "if I had been there I would not have shifted it yet." So much, we say, for the exception to the rule in that particular-sized pot.

You may have fine Camellias. I should not like to be the one to take credit for an absolute observance of any given code, with exceptional treatment, as they are very patient of fatigue; but if you wish a first-rate plantation of them, we would suggest dissimilar council. As long as they are in portable-sized pots, it is judicious to examine them every year. If scrutiny, such as the kind suggested in the preceding paragraph be necessary, by all means do so. If the ball is undisturbed by worms, its drainage perfect, the compost not at all enveloped and enwrapped with roots, place the pot in an inverted form, slip it cautiously again over the ball, turn the whole in their proper position, give the pot a "settle" on the potting-bench, see or feel with your thumb that there be no passage between ball and pot, so as water when applied may penetrate and percolate as equally in the centre as the exterior, and replace such plants in their proper position for another year. To those that require repotting observe the following treatment:—Recourse, in the first place, must be had to proper sensory measures, such as washing pots outside and inside, placing a large crock over the drain-hole or holes, and a good handful of smaller ones round about it so as to cover the entire bottom of the pot; and in order that the finer particles of earth may not be washed down amongst these tiles, &c., place a layer of sphagnum or fibry matter rid of

its finer particles, and then go to work with the soil, on the dry order, as diligently as you please, leaving from a quarter of an inch to a whole inch, according to the size of the pot, for a supply of water necessary to penetrate the whole depth of ball. With such you will have a sure foundation. An implicit observance of this will be specially necessary if plants and pots are large and intended to remain from five to ten years, which, in from 15-inch to 20-inch pots and larger, they are well able to stand. I may also remark and remind those who are not so well up in the art, what is of paramount importance—that the plants should be on the dry order; also, when they are examined and reported so as to admit of being more advantageously handled, in the broadest sense of the word, just for all the world in as good condition as you would expect the ground to be when preparing and sowing your Onion-beds.

Habit.—I do not know that it would be of much consequence generally to single out into groups those that have handsome and those that have ungainly habits; those that require to be starved, so to speak, and those that improve with generous treatment. Happily, however, those lanky ungainly fellows that have a tendency to become leadless below are not numerous. Having respect and veneration for old age, we question much if you could point out a more perfect example of good habit, and, I might add, decorative effect, than the old white (*alba plena*) herself. Of course she must give way to the finer-formed petal of Mrs. Abby Wilder, Teutonia, and Feastin, on whose merits we shall have something to say in its proper place; but these are far more fickle jades to induce to show their comeliness than their venerable and venerated grandmother. The most perfect habit of a *Camellia* of comparatively recent introduction is *Wilderii*. It is also a first-rate flower, and a free bloomer. It appears to me to be a distinct progeny of a handsome dwarfish order, with flowers of a medium size—something between *Sasanqua rosea* and *imbricata*. Taking habit and quality of bloom into consideration, I would say, keeping off some of the more recent introductions, which have not had a severe-enough trial, that *Valtevarada* and *Wilderii* are the two finest that we have of the rose-coloured tribe; but *Saccoi nova* will beat them both, and indeed all of that section, only it inclines as a plant to get somewhat bare at bottom.

Lady Hume's Bush, again, on the other hand, is about the most awkward habit, running all to terminals, of any *Camellia* extant; and the only way to do it well is to train up a single stem for 6 feet or 8 feet, like a standard Rose, and then tie down the laterals earthwards, and keep pinching and cutting them backwards until you form a bush. *Carswelliana*, *Matthottiana*, and others of that straggling class, would give much more satisfaction served in the same way. They, to be bloomed successfully, require a low diet at bud-setting time; although it is right to say that *Carswelliana* is generally a free bloomer.

The pyramidal form in the majority of instances is that most suited for setting off *Camellias* to best advantage; but there must be ample space in the growing season to give them full benefit of light and air, else the lower tiers of branches will give way. Such a form can be regulated if there is a fair sample to begin with, either by pinching out the wood-buds that are likely to go astray, or by using the knife to such as are counterbalancing a weaker side. In too many places, however, there is such a thirst for variety and numbers, that habit is quite overlooked. In nursery collections we probably cannot expect such a due observance of fine form, although we often have had occasion to deprecate the bare-legged plants that have passed through their hands, which are luxuriant enough but bear the marks of their lower branches being suffocated by growing too close together. We are aware that the Continent is the great mart of supply; for we have seen hundreds, I ought to say thousands, of them beautifully set with bud, come to a London nursery where the writer spent a part of his time. In garden collections there might be a more general observance given to this important point. To be sure, flowers can be produced of equally fine quality in plants that are allowed to, "hang as they grow," and good flowers in all places are the order of the day; but the artistic eye seeks for form as well as beauty, and the uneducated eye can all the more readily appreciate it if both have had a fair share of attention.

The bush habit is best adapted for very dwarf growers, such as *Princess Sophia* and *Wilderii*. Bushy heads of foliage have the far best effect in clear single stems, and show off any variety to good advantage. Those that have straggling habits, as was

suggested above, can be tied down to check the exuberant flow of sap; while those of general good habit can be trimmed like a Portugal Laurel or an imitation Orange tree, if such an artificial cut was at all desirable. No plants stand the free use of the knife better than *Camellias*. They break away when cut back either slightly or severely, so that if artistic effect be an object regardless of the sacrifice of a few blooms for a season or two to any very wayward subject, the operation can very safely be performed.—JAS. ANDERSON, *Meadow Bank, Uddingstone.*

DIGGING AND TRENCHING.

"D. W. P." and other correspondents having asked the charge per acre for these operations, we applied for information and the following is the result.

It is not easy to say how much a man ought to dig in a day, in the absence of all information respecting the kind of ground that is to be operated upon; but in Kent, where many thousand acres of orchard and Hop-grounds are dug over every year, it is customary to pay from 16s. to 20s. per acre, according to the description of ground to do, and this is not dug deep on account of the roots, neither is it broken after being turned over, but simply turned over in the rough. Trenching about 20 inches deep costs about 9d. per rod, or £6 per acre, and if the ground be stony the stones are generally picked out and paid for about 10d. per load or ton. Roots, if the ground had previously been a wood or plantation, are also paid for separately. The usual practice is to keep the top soil to the top again, unless the ground be very good indeed, and sometimes for particular purposes when a field is trenched, a number of men, and twelve perhaps, are divided the whole length of the furrow, and fork the bottom of each furrow up before the plough returns to cover it in. This is better than the subsoil plough; but as your case may perhaps not require work done on so extensive a scale, we may say that bastard trenching, which is supposed to be a good spit and a shovelling deep, cannot well be done under £2 10s. or £3 per acre, if done properly. Much, however, depends on this, as well as on the kind of ground to operate on.

MILDNESS OF THE CLIMATE OF THE FAR NORTH.

LET us first remind our readers that Stornaway is a town of Lewis, one of the most northern of the Western Isles of Scotland, being in N. lat. 58° 12'. Now, from thence we have received a note, dated the 3rd instant, obligingly written to us by Sir James Matheson, Bart., accompanying "specimens of the vegetation as indications of the temperature and climate of the place."

These specimens were as follows:—

- Spanish Broom, with shoots 3 inches long.
- Common Broom, flowers open.
- Daphne mezereum*, flowers opening.
- Rhododendron Nobileanum*, in flower, and has been so since January.
- Large Periwinkle (*Vinca major*), in flower.
- Euchsia*, leaf-buds open.
- Corkus* of Alder, Willow, Hazel, and Birch.
- Ribes sanguineum*, buds opening.
- Rose Dog and other Rose-buds opening.
- Elder, leaves 3 inches long.
- Whin, or Furze, in bloom.
- Daisies*, *Anemones*, and *Primulas*, in flower all winter.
- Snowdrops, in flower all January.
- Lonicera tatarica*, in full leaf.

IN MEMORIAM.

How strange the pranks that memory plays us, and how odd what people call association of ideas! Here am I now running my thoughts to some two and twenty years back! Again am I standing in a greenhouse, doubtless now numbered amongst the things of the past, watching, with eager eye, the gardener as he takes to the bench plant after plant; and, writing with an ecstasy of delight, which I fear it would now be impossible to raise, the names of *Pelargoniums*, of which, through the courtesy of the owner, I am receiving cuttings, and all occasioned by a

glance at the obituary of Monday's *Times*, in which I read "The Rev. RICHARD GARTH, of Farnham, Surrey, aged 71."

Yes, in that long-past time he, and one still amongst us, Mr. Foster, of Clewer Manor, astonished the world with the advance made in that lovely and popular tribe of flowers. "Garth's Sylph" and "Foster's Joan of Arc" were then the fair rivals, and well do I remember what a rage they created. Surely we had attained perfection, it was said; and now not one of the flowers of those days would be looked at—they were badly shaped and faint in colour. But none the less is the debt of gratitude we owe to those who saw what was to be done and did it. Each hit on a separate strain.

Mr. Foster's were rather more cupped in shape, and this they have maintained until the present time, although marvellously improved in size and shape generally; while the broad open petal has been seized upon by Mr. Hoyle, and under his judicious hands attained great perfection.

Some years after the period to which I allude, I chanced to be in Farnham, and called upon Mr. Garth. He kindly welcomed me, talked over his flowers; and, though he had even then withdrawn from raising seedlings, yet his heart was still in the work, and he watched with eager interest the labours of his successors. And now he is gathered to his fathers! His name will long live in the recollections of the elder generations of florists; and we, mayhap, may tell our children of the kindly and hearty clergyman, who, no way forgetting his own sacred calling, did yet contrive to interest, amuse, and profit many of his fellow travellers. He honoured the craft, and we trust it will honour his memory.—*D., Deal.*

SETTING CONICAL BOILERS.

I THINK, if your correspondent "P. W. M." will have his boiler placed upon the seating forming the sides of the furnace-hole, a distance of about 15 inches above the furnace-bars, and then carry the flue twice round the boiler, one above the other, he will find it heat to his satisfaction. We have three conical boilers here fixed in the above manner, which are all that can be desired. The difference of a few inches in the distance of the boiler from the furnace-door will not at all influence its heating powers.—*G. S.*

CONSTRUCTING A SMALL GREENHOUSE.

DIFFERENT sections of houses have been given lately which will suit your purpose. (We are answering "F. P.," of Galway.) You prefer a lean-to house. That is easiest kept heated, but unless where stone or bricks are handy, it is not the cheapest. However, keeping your requirements as to a lean-to in view, a house with 10 feet of a back wall, 12 feet wide, and 6 feet high in front, 11 feet long, will be a very nice little house, and so far as use is concerned, it matters not whether the back and front walls be of posts and wood, or stone, or brick. If of either of the latter, it would not be worth while to have them less than 9 inches thick. Posts 4 inches square, and boards 1 inch thick, would do if they should be preferred. If refused to make the front and ends with boards neat and secure, stretch stout calico over them, paint with anticorrosive, and throw on some white sand whilst wet. The back, if not seen, could be done with calico and tarred and sanded well. So much for the walls. Now, to secure ventilation and have a fixed roof. In making the back wall leave four openings at equal distances close to the apex, 27 inches or 30 inches in length, and 1 foot in width. These may either be closed by stout boards or a glazed frame of these dimensions. We have lately described several simple modes for opening or shutting these at pleasure. Now, the front being 6 feet, we would have 2 feet 9 inches of that wall, and 3 feet 3 inches of glass; but, allowing for the wall-plate—say 2 feet 6 inches of wall. Now, if economy is an object the front glass may also all be fixed, and ventilated similar to the top ones, secured in the wall below. Fewer would do both at top and bottom, if the door were left open in summer, or there were ventilators above the doorway and in the other end of the house. We have said what ventilation would be necessary without any such openings. We would pivot-hang all these ventilators, and thus do away with hinges. At page 352, you would

notice an account of rafter sash-bars. Yours for such a house will be 14 feet, a common length of battens, 9 inches by 3 inches, so that each batten will make four rafters, and these after being planed will be about $4\frac{1}{2}$ and $1\frac{1}{2}$. One inch thick would not be strong enough, and after a slip was fixed on would not allow enough of room for the glass, which must not be glazed tight. For each end you should have a rafter 3 inches by $4\frac{1}{2}$ inches, all the rest $1\frac{1}{2}$ inch by $4\frac{1}{2}$ inches before planing, &c. The glass may be 18 inches or 20 inches in width. We would recommend the first distance from the centre of one rafter to another if the place is at all exposed. Now, to keep out frost from such a house, an iron stove or an Arnott's brick stove will be sufficient; but for ease and neatness a flue would be the best. The whole question of flues and materials for the same have recently been discussed. Two bricks on edge would be sufficient for the depth of such a flue, the open inside being 6 inches or 7 inches wide. It might enter at the west end, and after passing the doorway pass round the front and out in the back wall at the other end. The stovehole at the end could be covered by a flap-board. If equally convenient we should prefer the stovehole to be behind the back wall at the south-west corner, and the flue could pass through inside the end of the house, but merely on the ground level until you passed the door and pathway, when it could stand all above ground and pass out at the back at the east end, or return along the back to a chimney near the furnace. See section.

- A Flue. Top on ground level or west end of the house, so as to allow pathway over it at doorway. The rest of the flue above the ground along the front and east end, and if deemed advisable returned along the back to the chimney over the furnace.
- B Dotted line to show fourteen-inch wall, or 18 inches to enclose chimney.
- C Dotted line at back, to show a shed if convenient. This will be best if roofed with glass, and besides keeping the furnace under cover, will be a good place for many plants and for working in. The heat from the furnace will pretty well keep out frost.
- D Back and front ventilators.
- E Front platform from 2 feet to 3 feet.
- F Stage at back. Many things at rest could be kept below the stage.

Three Vines might be planted in such a house, but they will shade plants in summer, but at that time a few tender annuals, &c., could be grown, as there will be plenty of flowers out of doors. With a shelf of from 2 feet to 3 feet wide in front, and a stage behind, the flue will not be seen at all. Such a house and especially with a shed behind, the roof partly or wholly of glass, would hold a great many plants and be productive of much pleasure. But, for the desire for a lean-to, we would have recommended a span-roof $7\frac{1}{2}$ feet high at ridge, 5 feet at front, and 12 feet wide, with path down the middle.—*R. F.*

TEMPERATURE OF VINERY.

Is a temperature of 13° too high in a vinery where there are also several plants? I was informed if more air was not admitted the Vines would be ruined.—*INQUIRE.*

[Never mind what the wise people say. At that temperature, 13° , the Vines are safer than if at 23° or 33° , and they will scarcely come a day before their time. You may keep them all the winter from 38° to 45° and do them no injury, and keep your plants well too.]

METEOROLOGY OF 1859—60—61 AT CULFORD, NEAR BURY ST. EDMONDS.

Highest Temperature of 1859 occurred on July 18th, 89°. Of 1860 on July 12th, 76°. Of 1861, on August 12th, 83°.

Lowest Temperature of 1859 occurred on December 18th, 38°. Of 1860, on December 21st, 0—3°. Of 1861, on January 7th, 0°.

Mean Maximum Temperature of 1859, 57.3°. Of 1860, 53.65°. Of 1861, 56.72°.

Mean Minimum Temperature of 1859, 43°. Of 1860, 40.41°. Of 1861, 44°.

Mean Temperature of 1859, 50.25°. Of 1860, 47°. Of 1861, 49.37°.

Amount of Rain in 1859, 37.07 inches. In 1860, 39.20 inches. In 1861, 11.51 inches.

NOTES FROM MY HERBACEOUS GARDEN.

(Continued from page 277.)

I WILL proceed now to give in as concise a manner as possible the directions followed in supplying six more beds; but must curtail the information, as the subject is lengthening beyond what I first anticipated.

NOTES ON BEDS 6 AND 7.

No. 6 in autumn was filled with variegated Box, which was grown in pots plunged in the reserve garden for the purpose. An edging of Pansies was given here. The Box was removed again in March to make room for the scarlet Brompton Stocks. The Pansies will remain till the Stocks have done flowering.

No. 7 was filled with Irish Yews, and an edging of Pansies was added here. These, too, will remain till the purple Brompton Stocks, which are coming here at the same time as the scarlets, have done flowering.

The following is a short treatise on the way these Stocks were grown. Seed was sown the first week in June; the seedlings were pricked out into a piece of rich soil at the end of July, and at the end of September were taken up and replanted in the same soil. The object of this move was to arrest the vigorous growth, and cause them to become stout and stocky. Taken up again in November, they were placed singly in 48-sized pots, there to remain under the shelter of a roughly-constructed pit to the time of their being finally placed in their flowering-beds. I have never seen a better system of growing them. It is a simple method certainly, and their noble spikes of fragrant flowers amply repay for this additional trouble of removing. But March is fast closing upon us; the Stocks are still in their pots, but I will remove them at once to their flowering-quarters; and will first plunge the Box and Yews again in the reserve garden. The Pansies are flowering nicely, and, in conjunction with the surrounding spring bulbs, have a good effect. I anticipate a gorgeous display of flowers from these two beds of Stocks. I will not fail to assist them with good doses of manure water should dry weather set in. A week hence, and I will sow a large pan of German Asters, to take the place of the Stocks about the beginning of July. As soon as the Asters are up and large enough to prick out I will place about four of them round the rims of the pots from which the Stocks come; these can be turned out with the balls entire as soon as the Stocks have done flowering. No time will, therefore, be lost in this case, as the Asters will soon flower, and continue on till bad weather in autumn.

A good batch of cuttings has been taken from the Pansies, and the old plants taken away and committed to the rubbish-heap.

BEDS 8 AND 9.

The centres of these were filled in autumn with the common Lent Lilies. No. 8 had an edging of the American lilac Primrose; while No. 9 received an edging, for a permanency, of the little Phlox oculata. This Phlox, if not removed more than once in four years, will flower in the month of April and onwards through May in great profusion. It should receive annually a little sifted dry earth in the autumn strewn lightly over the plants, as the roots spreading naturally very shallow become bare and exposed through the continual heavy rains. Nothing more was done here till the April showers had warned me that the double purple and white Rockets, which are coming here to bestow their delicious fragrance, would remove now without fear of any check. The Lilies only will require moving now, so there is nothing to forbid the Rockets being brought here at once. The white Rockets will occupy No. 8 and the purple No. 9. Had it been considered necessary these would have been planted here in the autumn, as has been recommended for most other kinds of herbaceous plants; but they care so little about mowing that I would not mind venturing to do so when they were in full flower, if I wanted immediate effect.

The double Rocket may be increased by division of the root at almost any season of the year; but a more speedy method of getting up a stock is the following:—Choose two or three strong plants, and as soon as these have thrown up flower-stalks to the height of a foot and a half cut them down to within 4 inches of the bottom. The stools will soon produce a number of side shoots, and when these shoots have attained the length of 3 inches slip them off with a heel; insert them under a hand-light in a mixture of leaf mould and sand, and in a few weeks they will be found to have made good roots. To those not practically acquainted with these plants I will here add that

the purple in most situations grows a foot higher than the white, and is generally three weeks later in flowering—viz., the white in June and July, and the purple in July and August.

After the Rockets had ceased to flower in No. 8 they were removed again to the reserve-garden. I have already a substitute in readiness to take their place in the *Lycynis chalcidonicæ*, or double scarlet *Lycynis*. This, I think, must be a stranger to some of your readers, as it is but rarely to be met with. All who know the brilliant scarlet of the single *Lycynis* cannot but admire its glowing colour. If the double does not surpass the single in richness of hue, it certainly is not wanting in any other point, but might be placed as a fit companion for its single relative. Its removal here from the reserve garden will produce a slight check on its flowering; consequently it will furnish flowers later in autumn.

The following is a quick way of getting up a stock of the double *Lycynis*:—Place three or four plants in a light friable soil, and take out all flowering-stems for one season. This will cause a greater action to the roots, and a greater number of offsets will be the consequence. Divide these in early autumn, and, where practicable, place them where they are intended to flower.

BEDS 10 AND 11.

No. 10 received for the winter about a score of plants of the *Berberis aquifolium*. The beautiful yellow flowers of this hardy shrub in contrast with its dark glossy foliage in spring is truly grand, and in conjunction with No. 11, which was filled with the crimson *Pæonies*, had a very striking effect, notwithstanding that the former had nearly spent its flowers before the *Pæonies* were in their beauty. But I ought before to have remarked that No. 11 received in the autumn, to stand till the beginning of March, some well-grown plants of Red Cedars. On their removal the *Pæonies* took their place. The *Berberis* was removed the third week in May, which was late enough, to allow for *Carnations* and *Picotees* to flower the same season in the same bed; but then these were grown in 21-sized pots. This was compulsory; for we were so infested with hares and rabbits, that to put them out earlier would have endangered their lives. A few seeds of Ten-week Stocks were sown at the time of turning the above out in some of the bare spaces between the plants. Thus we insured a later succession of flowers than the *Carnations* would give us.

No. 11 was recruited at the same time. This was the first trial of removing the *Pæonies* immediately after flowering, and I have no further notes that would justify me to advise doing so, although, were I appealed to for my opinion upon the matter, I should give it in favour of removing. This much I can say in favour of clumping them—a more gorgeous spectacle never before greeted my eyes than this bed for the space of a month.

Cleanliness with respect to clearing off all loose petals and decayed flower-stalks is an essential point in their favour; and where order and neatness reign it will be attended to in this case daily. But like all other beautiful flowers, the time to cease flowering comes too soon, but not too soon for the coming successors, for they are already bursting their flower-heads. The *Potentilla* is the plant in question, of which we have purposely preserved several varieties with the intention of testing their hardiness and long duration in flower. I can speak of them for both qualities with confidence, having grown a few in the mixed borders. They will be brought to this bed at once, lifted with good balls of earth, where I doubt not they will furnish a good display of flowers for the summer.

What followed the double Rockets in No. 9 must be omitted for want of sufficient notes.—J. C. CLARKE, *Wakchurst Place, Cuckfield.*

CULTURE OF THE OSIER WILLOW.—Having lately seen several inquiries respecting the Osier Willow and its culture, and being asked almost daily, "Do you think it will pay?" I have concluded to send you my experience in its cultivation. Three years ago this spring, after corn-planting, I set two acres of the French Osiers, placing them in rows 3 feet apart, at a distance of 1 foot from each other. The first year I cultivated and hoed the same as corn, and many of the shoots attained the height of 4 feet. The next spring I cut them, but, having no machine for peeling, lost the crop, except a few used for sets. Last spring I cut and commenced peeling by hand, which I found rather an uphill business, and almost resolved to abandon their culture if

they must be peeled in that way. About this time a machine was invented for peeling Willows. I immediately procured one, which worked to my entire satisfaction, and with it finished peeling my crop, which when ready for market, including some sold for sets, a little exceeded a ton. These I shipped to a commission merchant in New York, and received for them 110 dols. per ton. This year I have a much heavier crop. For an experiment I have weighed those cut from twelve stools, which amount to 18 lbs. I have found in peeling and drying they waste nearly one-half. The produce of an acre stands thus:—14,520 stools per acre, 1½ lb. each, 21,780 lbs. Ready for market, 5½ tons, 110 dols. per ton, 605 dols.; cost of cutting, per acre, 6 dols.; cost of peeling, per ton, 7 dols., 38 dols.; binding and taking to market, 5 dols. per ton, 27 dols.; total, 72 dols. Deducting expenses, this leaves a profit per acre of 533 dols. According to directions received at the time I planted, I have not cultivated mine since the first year, but think they should be cultivated once every spring, to loosen the soil and keep them free from weeds and grass. I am confident that any one who has suitable ground, and will bestow proper cultivation, can realise this amount from an acre of Willows, perhaps more. After reading these facts I think no one can hesitate how to answer the query, "Will it pay?"—(*Rural New Yorker.*)

ENTOMOLOGICAL SOCIETY'S MEETING.

THE first Meeting of the Entomological Society in the present year was held on the 6th January, the President, J. W. Douglas, Esq., being in the chair. The alterations intended to be proposed in the lists of the Council and Officers for the ensuing year were announced by the President, the chief change being the substitution of H. T. Stainton, Esq., as President, in lieu of Mr. Douglas, who retires from length of service; and Mr. Dunning as one of the Secretaries in the place of Mr. Janson.

Mr. F. Smith exhibited the nest of a Bee of the genus *Anthidium*, from the Cape of Good Hope, collected by Mr. D'Urban, some of the cells in which were still stored with honey and pollen; but in other cells a parasitic kind of Wasp, belonging to the genus *Leucospis* (belonging to the family Chalcididae), had been developed, which had destroyed the Bee-larvæ. He also exhibited several of the spines of a species of *Acacia* from the Cape, in the hollow portions of which several specimens of another kind of Bee, belonging to the genus *Hylœus*, had been developed, and which had made their escape by a hole bored near the tip of the spines. The eggs, pupæ, and perfect Bees were discovered within the spines when opened, the pupæ not enclosed in a cocoon, as is the case with the pupæ of most kinds of wild Bees (which habit is not, however, adopted by the *Hylœus*). Mr. Smith also mentioned that he had once found a piece of flint, in a hollow depression of which he had found more than twenty immature *Hylœi*, lying without any cocoon-like covering.

Dr. Krugers exhibited a number of the curious cases (like those of Caddis Worms, only much larger in size), formed by the caterpillars of different gigantic species of *Psychæ*, or *Oiketicus*, in New South Wales. One of these cases was several inches long, and its outer surface was defended by a number of pieces of twigs arranged longitudinally. (The Moth of this species had been described by Professor Westwood under the name of *Oiketicus Saundersii*, having been received by W. W. Saunders, Esq., Treasurer of the Horticultural and Linnean Societies, from Australia, where it was collected by Mr. Stephenson.) Other cases had the twigs arranged transversely, but one of the most curious (of which the Moth has not yet been discovered) was entirely of a leathery texture and oval form, with strong longitudinal ribs of the same texture.

Mr. G. R. Waterhouse exhibited a new British species of *Staphylinidæ*, of small size, from the collection of Dr. Power.

Mr. F. Bond brought some slabs of pressed peat, which formed an excellent substitute for cork in lining the drawers of insect cabinets.

Mr. Dunning exhibited a photographic representation of a remarkable specimen of the Magpie Moth (*Abraxa grossulariata*), from the collection of Mr. Gregson, stating that the yellow colour of portions of the wings, generally so difficult to be treated in the photographic camera, had been neutralised in this instance by the employment of a piece of green glass placed between the insect and the lens. Mr. Dunning also read a communication on breeding varieties of insects, by feeding the

caterpillars with different kinds of food plants. By a series of experiments extending over the last ten years, he had been able to obtain considerable modification in colour in a great number of species of Moths; by this means Mr. Gregson considers it possible to obtain a permanent series of varieties. This paper led to considerable discussion with reference to the question of local permanent varieties, as well as to the specific rank of many of the so-called species of Microlepidoptera, which have, of late years, been reared with so much success.

Mr. Stainton read descriptions of nine new exotic species of small Moths, belonging to the genus *Gracillaria*, from Moreton Bay, Australia, collected by Mr. Diggles, and from Calcutta by Mr. Atkinson. Some of the species were extremely beautiful; their habits were, however, precisely similar to those of our own country.

Mr. MacLachlan read a paper containing descriptions of a number of exotic, as well as of one new British species of Trichoptera, the latter had been at Shirebridge, Devonshire.

Mr. F. Smith read a note by Mr. Woodbury in opposition to the views of Principal Leitch (communicated to the Society at the October Meeting by Mr. Tegetmeier), on the development of queen Bees by the supposed action of heat engendered by the congregation on the outside of the queen cells of large numbers of Worker Bees (in opposition to the generally-received opinion that the development of the queen was owing to a special kind of food). Professor Westwood also opposed Mr. Leitch's views, considering that were heat the chief cause of the development of the fuller powers of the queen, the queen cells would always be found in the hottest part of the hive, instead of being placed along the outer margin of the combs; besides, it was necessary that the theory should be equally applicable to the development of the workers and queens of the Vespiary and Humble Bees, as well as to the two kinds of workers and queens of the Ants.

GENERALLY USEFUL CULTIVATORS.

COW MANAGEMENT.

(Continued from page 297.)

In my last we left off with the milking, supposing the cows are milked thoroughly clean; because, not only is the last half-pint of more value than the first quart, and gives the richness, colour, and firmness in good butter, but that quantity left in the cow's udder each time, or even occasionally, has a tendency to dry her, or reduce the quantity of milk.

Now, having arrived at the dairy with the milk, the milk-pans being ready, with a sieve in one of them, the milk must be strained through it, an equal quantity in each pan; then put sufficient clean water in the milk-pail to rinse it out, and, if more than one milk-pan, divide it equally—I believe it to have a beneficial effect. In cold weather I put warm water. Now, if the milk was taken to the dairy, and there left for the cook to put in the pans, in the morning probably she may have work to do that will prevent her attending to it immediately, or it may be forgotten; and in the afternoon, just as the milk is brought in, she is just about to dish up the dinner, and by the time the dinner is sent in, and she is cooled a little to venture into the dairy with the windows all open, the cream has formed on the milk, and not only is there a good part left on the milk-pail and strainer, but the cream never rises so well after, and, as a matter of course, "don't pay."

I may as well say a word or two respecting the management of the milk in the dairy. The other day a lady neighbour was speaking to our cook, and complaining about her butter, and amongst other remarks, she said, "I never get good butter." She saw and tasted the butter made here that day, as she had many times before, and she asked, "How do you manage your milk?" Now, there is no rule to be laid down that any one without judgment can follow; but it must be regulated according to circumstances. Our cook (and it is a rare occurrence for her to have anything the matter with her butter) takes the cream off the first time after standing twelve hours or so; and if the weather is hot or sultry, as in summer, or dull and muggy, as in November, she puts it into a clean milk-pan, and if she skims it more than twice (which she always does if the milk is not wanted), the third skimming she does not put in the cream-pan for butter, but makes use of it for pastry or melted butter. The cream must be well stirred up in the pan

daily, and as we now only milk one cow and churn but twice in three weeks, it will require to be scalded and changed to a clean pan two or three times. She never scalds her milk, and only on such occasions the cream; but with all this precaution the butter may be spoiled by the feeding of the cows.

Where there is more than one cow kept, it is time one should be dried for calving. I manage to bring them in at least three months apart, and cease to milk eight weeks before calving, but do not cease milking all at once. The last week milk only once in the day—this milk will be good. Afterwards, take a little just to keep the udder from straining for the next week, and give the dry cow the tops and bottoms of the rick. If you have not one dry, put it by till you have, because you must take part of the responsibility if the butter is bad.

As in some instances you will have to churn, or assist in churning, I may as well say a few words on the subject here. Modes of churning have been advocated in this Journal, and some few years ago some one suggested the idea of having the churn attached to a steam engine: where the quantity was great, and the person superintending had command over the steam, there could be no objection. Another, or the same individual, could see no reason why churning could not be done in the nursery (placed inside the rocking-horse, I suppose). As a piece of amusement, no doubt it would answer admirably, particularly when it came to the making of the pats. But I am not sufficiently advanced in science to advocate either of the above. Still churning is not a mechanical operation only. It requires thought and judgment, and more scientific knowledge to describe the why and the wherefore than I am possessed of. In the summer, when the weather is warm, the cream must be often changed into a clean vessel and kept as cool as possible, and the churn filled with cold water the day before using it. It must be churned very slowly, and should never be churned under three quarters of an hour; otherwise, the butter will not get firm. The buttermilk must be well worked out of it with the hand. If the hand is at all inclined to be warm, she holds it in water as hot as she can bear it, and puts a cloth round it, else the butter will be streaky when it is cut, and will keep but a short time. After being made up and placed upon a clean dish, it should be placed on the coolest part of the dairy floor, and not in water, as some people do.

At this season of the year the cream should be brought on the kitchen table a night or two before churning, and the churn well warmed with water, and all the rinsing done with warm water, and then the churn brought into a warm room. Care must be taken, and not turn it (the barrel churn) too fast at the beginning, else the cream will be got into that state that is called "asleep," and will not move at all, and will remain so for hours. People are apt to put water in then to thin it, and the result is too often that it goes into the pig tub; but should it get into this state, put in a clean plated spoon, or something of the kind to separate it. The object is to get it to move. It is produced by fast churning: therefore, you must exercise your judgment, and prevent it at the beginning.—THE DOCTOR'S BOX.

TRANSPLANTING MODERATE-SIZED EVERGREEN SHRUBS AND TREES.

For the information of those whose intention it is to carry on transplanting operations during the present winter and spring, not being provided with the regular transplanting machinery, I beg to offer the following observations:—

The tree or shrub is first prepared by opening a trench all round, and at a sufficient distance from the stem to prevent cutting the roots with the spade. After getting down about 2 feet, take a small four or five-toothed tan-fork, and remove the earth gently from the ball, in order to save as many of the fibres as possible. While removing the soil, great care is requisite to keep the ball of earth as perpendicular as possible, even below what is intended to be the under surface, and on no account undermine until the ball is sufficiently bound up. Carry on the reducing of the ball in a perpendicular manner till within a foot and a half or 2 feet of the stem; this, however, must be judged according to the size of the plant, the matted nature of the ball of earth with the roots, or to the strength which can be commanded at the time of lifting. Where human exertion is to be the raising power, it is better to curtail the ball of earth, so as the strength at command will be sufficient to raise the mass without difficulty, or stressing the individuals, which is not unfrequently the case

when too much is attempted; besides, the plant is apt to sustain injury by the loosening of the soil from the roots, whereas, if a smaller ball of earth were attempted, the risk of injuring to the plant is much less. Supposing the ball of earth reduced to the size required, the strong roots, if any, should be cut close to the surface of the ball, and the smaller or more flexible roots tied to the remaining mass. Round the ball of earth and roots place some soft straw or hay, and surround the whole with a mat, previously doubled longways, keeping the doubled portion lowermost, but not below the level of that part of the ball intended to be the bottom; this, however, must be judged according to the depth the roots are found. Sometimes the ball will be found to bear a much greater proportion of depth than breadth, but more frequently the reverse. After adjusting the mat properly, tie round it loosely, within 6 inches of the top, and 6 inches of the bottom, a piece of untarred yarn or packthread, and then place between the yarn and mat a sufficient number of pieces of thin boarding, each varying from 2 inches to 3 inches broad, of equal lengths, and from 3 inches to 4 inches apart all round the ball, keeping the yarn of sufficient tightness to adjust them properly, and at the same time to prevent their falling down. The most convenient wood for the purpose is barrel staves, keeping the concave side next the ball. After the spars or staves have been properly arranged, a strong half-inch tarred rope doubled must be put round the upper part of the

Fig. 1.

ball, making it fast in front, but not too tight, take the remaining portion of the doubled rope under the front, as in fig. 1, and surround the ball with it again near the bottom, afterwards twist the ends of the rope several times round the lower double each way, so as to fix it without having recourse to knotting, which must always be avoided. After the ropes have been adjusted of moderate tightness, place under the rope at each side of the ball a small piece of packthread or tarred yarn, about 12 inches or 14 inches long, one on the upper, and the other on the under rope. Wreck sticks must be used both on the top and bottom ropes, and on each side, then wrack both up gently, and at the same time twisting up the ropes to a sufficient tightness, then tie the ends of the wrack-pin down with the piece of short rope yarn previously put in.

The method just described is quite sufficient for ordinary-sized balls, but if the mass is large, it is necessary to use large ropes, and two wracks upon each rope.

Supposing now that the ball is firmly bound together, begin to undermine on one side; but, before doing so, it is necessary at this stage of the operation to consider which way the plant (tree or shrub) can be easiest taken out from the shrubbery in which we shall suppose it to be growing. If cress is easiest afforded on the south side, the undermining must take place on the east and west sides. While undermining the one side, it is necessary to put a prop between the ball and the bank on the opposite side, so as to prevent the possibility of the ball slipping down, until the undermining is completed. If the ball is solid, much of the earth below not containing roots can be removed with propriety; but if loose, it is requisite to put a little straw or soft mat pad, and then insert a strong board varying from 6 inches to 8 inches in breadth, and of such a length as to project beyond the ball at each end about 2 inches. When the one side is finished, remove the prop and allow the ball to lean gently down on the lifting-board just put in; remove now the loose soil from the opposite side, and place below a little straw or soft mat pad, and a corresponding lifting-board to that used on the opposite side. This operation completed, the plant will rest wholly on the lifting-boards. The next process is to remove the loose soil from under the ends of the boards on one side. Two strong tarred ropes, each 10 feet or 12 feet long, being in readiness, one is worked under the ends of the boards at one side, and the other under the opposite ends. Another way is to put them in at the time the bottom boards are being placed. The ropes should be worked under the boards about one-fourth from each end, dividing the rope as near as possible. Fig 2, *a* represents the lifting-boards with the ropes under; *b* represents the boards and ropes with handspeikes attached. If the plant is not of large size, the tying of the ends of the ropes together will be sufficient, but it not unfrequently happens that the ropes get together on the handspeikes, unless some contrivance is used to prevent it. Notches cut out of the boards as shown in

fig. 2, *c*, or pieces attached to the bottom of the boards to keep the ropes from moving, as on fig. 2, *d*, are useful enough. It

Fig. 2.

often happens that the lifting-boards must be sacrificed, as shall afterwards be explained: it is, therefore, needless to go to expense with them. To prevent the ropes getting together, it is necessary to fix a loop at the extremity of each rope, taking care that they shall be all the same height above the level of the ball, and so made as not to slip, and at the same time to be easily unfastened. Into the eyes formed on the ropes place strong handspeikes parallel with the bottom boards, 7 feet or 8 feet long, according to the mass to be lifted.

After the above arrangements are completed, sufficient strength must be got to raise it. As the most difficult part of the operation is the removing the mass from the hole in which it has been growing, and not being provided with a regular transplanting machine. In ordinary cases, the plant, if prepared as before described, may be easily lifted and conveyed away; but if too large to be raised at once, the task becomes more difficult. Various methods may be suggested for getting the plant out— one, by cutting a sloping bank from the surface of the ground to the bottom of the hole, and working the plant gradually up the slope. With heavy plants, this method is preferable to lifting it at once, which is apt to stress the men employed; besides, the difficulty of getting the handspeikes low enough so as to have sufficient purchase when the lower part of the ball becomes near the surface of the hole. The following is the method which I generally adopt when the mass is large, and which prevents the possibility of any of the hands sustaining injury:—While the plant is still resting on the bottom of the hole, with the necessary ropes and handspeikes appended, at one side place a few men to keep the handspeikes tight, so as to prevent the ropes from slipping through with the extra strength placed on the opposite side for the purpose of lifting that side; when raised, fill up the side lifted with earth about 6 inches or 8 inches, add firm it well down, putting it as far below the plant as it can well be got. This being done, place the smaller strength on the side lifted, and the greater on the opposite, so as to raise it up also, and fill in below as before; carry on in this manner, gaining about 6 inches each time, until the plant is brought to the surface of the ground. This done, spread out a large bast mat, strong and quite entire, having all the ends tied as short as possible, place the plant on the centre of it, and tie the ends up to the handspeikes on to the ball as tight as possible, so as to prevent the possibility of the loose earth from the bottom dropping out either while carrying it to its destination, or placing it on a

machine for the same purpose. As the mat has to be drawn from below before planting, great inconvenience is occasioned if it is in holes, or has loose ends hanging down, catching on the ends of the lifting-boards and spars. Trifling as this observation may appear, it is of the utmost consequence while carrying on the work. Supposing the plant fairly out of the hole, and mat fixed under it. If the distance is short to the intended place of reception, it could easily be carried. (Fig. 3 represents

Fig. 3.

a plant prepared for being carried, but without the mat surrounding all. It was left out in *figs.* 3 and 5 in order to show the position of the ropes and staves). If the plant has to be conveyed to a distance, it is necessary to be provided with a low broad-wheeled transplanting-truck, *fig.* 4.

The surface of the truck must be strong, and made to extend a little over the wheels on each side. Such a machine as that used by masons for carrying large stones from place to place is preferable, owing to the ease by which it can be made to turn. The wheels had better be of solid woodwork, not less than 5 inches

Fig. 4.

Fig. 5.

broad, and surrounded with a broad iron hoop, thus rendering it less liable to injure garden walks. Several strong rings should also be placed about it, in order to secure the plant by ropes if required, particularly while going over an irregular surface.

Supposing the plant brought to a situation where it can be easily got upon the machine, the handle must be raised up so as to make the back part of it touch the ground; the plant is then to be raised on, and the handle or shaft gradually lowered, keeping sufficient strength behind to prevent the plant being upset while bringing it to a level. *Fig.* 5 represents a plant so placed on the truck. After being secured, the handspikes may be taken out, and the ends of the ropes firmly secured to the upright staves or spars.

After being properly secured, little difficulty will be found in transplanting it to its intended place of reception. Previous to its being removed, the hole or pit into which it is to be placed ought to be in readiness, and at least 4 feet larger than the diameter of the ball of earth and roots to be placed into it. A sloping bank must be formed from the surface of the ground to the bottom of the pit, the machine with the plant must then be brought as near to the edge of the slope as possible, and placed with the back part of it to the pit. After the ties have been unloosed which fixed the plant to the machine, replace the handspikes and equally adjust the strength as before, placing one or two men to steady the top of the plant. All being in readiness, raise up gently the shaft of the machine, and the mass will be easily slipped to the ground. This done, unloose the ties of the outer mat, and raise the plant with the handspikes sufficient to draw the mat from beneath; then slip the plant gently down the inclined plane into the pit. If possible, prevent it from being dragged down, as it is apt to take in a quantity of earth, besides displacing the bottom boards, and the risk of loosening the whole mass.

If the ball of earth enclosing the roots happen to be too heavy to be lifted upon the transplanting-truck at once, it may be put on in the following manner:—After the plant has been raised, and resting on the surface of the ground, a slope can be cut in the earth close to where the plant is standing, sufficiently wide to allow the transplanting-truck to be let down on planks previously laid for the purpose, and of such a depth behind, that the back part of the truck shall be on a level with the surface on which the plant is standing. When so arranged, the plant can be worked upon the truck, and then drawn to the surface of the ground.

Fig. 6 represents a plant ready to be placed on a truck.

If the tree or shrub intended to be transplanted happen to be growing on a sloping bank, it is easily got upon the truck by cutting a trench into the bank where the plant is standing; and if its destination happen to be on a sloping bank, a trench can be cut so as to allow the truck to be run back; the plant can then be slipped off the truck on a piece of ground previously prepared for its reception.—JAMES M'NAB, Curator of the Royal Botanic Garden, Edinburgh.

Fig. 6.

EXPERIMENTS IN CULTIVATING THE POTATO AT MOUNT SHANNON,

BY MR. ROBINSON.

THE Potato crop was planted in drills, and in these the experiments were made. The planting was perfectly uniform; the soil, the time, the site, the seed, and the preparation all alike. The seed, which was cut in the ordinary manner, comprised two kinds, Scotch Downs and Leather Coats. The entire quantity of land planted with the esculent was four Irish or six statute acres.

The planting took place after the 10th of April.

On the 20th of July, about nine o'clock, P.M., whilst passing Peafield, near Anacott, Mr. Robinson perceived, by the peculiar odour, that the blight was even then an unwelcome visitor; and on the following Monday, after examination, found that the plantings under his own care were affected. It was necessary, therefore, that something should be done to try and arrest the progress of the malady; and on the ensuing Friday he instituted the experiment.

He resorted to two expedients. He had a small section of land occupied by seedling Potatoes, and on the 26th of July he had the haulm or stalks of these laid—that is, bent down, with the foliage drooping into the furrows; and on the following Monday, the 28th of July, he had the greater portion of the general crop treated in a similar manner. A man or boy took and turned two or three stalks at a time, laying them with the foliage pendent as stated, and then a good spit of earth having been dug between every two of the drills, a sufficient quantity was carefully laid on the off side, not quite on the top, of each drill, so as partly to cover and keep the haulm down. The greatest portion of it affected by blight, as well as the foliage, was thus bent down, and in such a way that both could be washed with rain into the furrow, in place of remaining in an upright position, in which the vitiated or poisonous matter would freely descend and taint the tubers. Of the six statute acres two were thus laid; a half acre next them left standing as it grew; half a rood of the drills parallel with the former cut down with a weeping-hook, and covered over with soil from the furrow, so as to rise over the naked stems; one other acre then laid like the two first; and, lastly, one rood, or rather more, of the drills left upright like the half acre already mentioned. Thus there were such alternations of the several processes in various parts of the field that no special advantage could vitiate the truth of the experiments. We come to the results.

A trow was taken, and 7 yards or 21 feet of two laid drills measured; a similar length of two drills alongside the former, in which the stalks were left standing, measured in like manner; and an equivalent length of a couple of drills, in which the stalks had been cut, marked out in the same way. In two other portions of the field the like measurement was made: so that the trials were allocated to the lower, the middle, and the upper parts of the land. All those measured lengths were fairly dug out, and the produce exposed just as it was turned up. The Potatoes were counted, examined, and weighed in the presence of the gentlemen who were present, and the result ascertained to be, that five times a greater quantity of bad Potatoes were found in the drills that had grown in the upright or the usual way, than were found in those which had been turned down with the foliage pendent into the furrows. We saw the tainted tubers counted in the drills, in which the stalks were left upright, and the number in the 21 feet was one hundred and twenty-one; whilst in the like space of the two contiguous drills, of which the stalks were laid down and earthed in the manner directed by Mr. Robinson, the number of bad tubers was only nineteen. In the second trial, according to weight, there were 135 lbs. bad, or nearly a stone out of the produce, of four stone in the unlaid drills; whereas there were only 2½ lbs. bad out of a similar quantity dug from the two parallel drills that were laid. Thus, in every 20 feet of the latter, 1½ lbs. of Potatoes were obviously saved; and any of our readers who will take the trouble to calculate the collective quantity which would be yielded and saved from a single acre at this rate will ascertain the money's worth of the perfectly easy and practical experiment tried and proved by Mr. Robinson. How enormous to the whole country such a saving must be will be admitted by all who know the unapproachable worth of the Potato crop as a staple food of the people, and of the live stock which agriculturists rear.

The cost of laying down the drills as described, would be from 1l to 25s. an acre, to those by whom hired labour should be

engaged. To occupiers having hands and legs of their own, of course the expense would be infinitely less. The effect of the earthing over the laid drills was, as you could observe at a glance, highly beneficial to the land itself, for it had stifled the weeds in their infancy, whilst the unlaid drills were nearly overspread with the growth.—(*Munster News*.)

THE POTATO DISEASE.

"Castlemartyr, Nov. 18, 1861.

"I OBSERVED lately in your paper an allusion to the system of earthing over the Potato-stalks, as protection from blight. Having heard of its success on Lord Clare's farm, at Mount Shannon, I this year caused a drill to be earthed over in each of two plots of Potatoes. Each plot was then just exhibiting the first spots of blight. The stalks were laid down by the hand, not cut off, and were completely earthed over.

"When the crop was lifted there was a considerable portion of diseased tubers, though certainly less than last year. But in the drills earthed over, in both plots, and both varieties of Potato, there was not a single diseased tuber, and I considered the produce to be better and drier than even the sound tubers of the rest of the plots.

"It may be a question if the labour of this system would be repaid in a very extensive crop; but to small farmers and cottiers, with small extent, I think it may prove valuable.

"I remain, sir, your obedient servant,
—(*Cork Examiner*.)

"SHANNON."

STRIPED BORDERS, AND SUITABLE PLANTS TO MAKE THEM WITH.

A CORRESPONDENT, in a former Number of THE JOURNAL OF HORTICULTURE, having invited planters to make a report on what they considered was the best bed of the season in their respective gardens—a request which I hope will be duly responded to, and one which I myself will have great pleasure in giving my views upon on another occasion; but in addition to the inquiry after the best beds of the season, I also put forth another inquiry: Which are the best plants to make a striped border of four rows—all facing one way? In asking this through the columns of this periodical, I will at the same time give some examples which I have tried here; but as none of them were to my mind perfect, it is only right to point out what I consider the defective features of them, in order that those who may in future be disposed to form such borders may fully comprehend the merits and failings of such plants as have been tried. I will also make a few remarks on what I consider a plant for a striped bed ought to be.

At what precise time beds or borders of flowers planted in continuous stripes came into fashion it is impossible to say; but the first that I ever saw, and which, in richness of colouring, has not been surpassed by anything I have seen since, was of Crocus, and that some thirty years ago or more, the custom then not being a new one. Of late years, however, it has been a common practice to dignify old customs with new names, and the term rainbow-border or ribbon-border, has been thought to sound more refined than plain striped border. Be this, however, as it may, it is enough for the reader to understand that such borders form a very important feature in most flower gardens now-a-days, and the proper planting of them is one that requires as much taste and judgment as anything in the floral department, that where successful hits have been made, I hope the fortunate ones will not hide their light, but at once expose it to the world; for it is possible the best arrangement yet made may have been at some obscure place which the mass of the gardening world would have but little chance of hearing of, excepting through the columns of a periodical like THE JOURNAL OF HORTICULTURE. But as certain conditions seem requisite in a plant to make it suitable for this class of ornamental gardening, it is only fair to point out what I consider these qualifications to be.

The Necessary Qualifications of a Plant for a Ribbon-border.—Many of the best bedding plants we possess are unfit for this purpose, or at least for the generality of cases, when the lines of colouring are less than 18 inches wide. Verbena of most kinds are too rampant, loose, or spreading, so that it is only the upright growers which are fit, as for instance, Verbena Purple King, one of the best, if not the very best, of all the Verbenas. There are some other Verbenas of similar habit, but I instance this one as being well known. Plants with pendulous flowers are also unfit, and such plants as do not possess that sturdiness of habit necessary

to carry them through the whole of the season with a respectable appearance, ought also to be disqualified. This will exclude most annuals. Plants of unruly growth must also be denied here, unless such growth can be constrained to take that proper form which it ought to take in the company it is in. Some other classes of plants are also unfit for this work. But enough has been said on this head: it is therefore better to consider what descriptions of plants are best adapted, and the reasons why they are so.

In the first place it is right to say that, notwithstanding the long-continued blooming of many of the most popular plants our gardens now boast of, the plant of all perennials at least outlives the flower, often by several weeks. Whenever, therefore, we can have an ornamental plant, it is better than an ornamental flower, for the latter is never produced in such profusion as the foliage, and is not liable to those fluctuations which the ever-changing character of our climate renders so certain: therefore for most purposes a plant with foliage of the required colour is preferable to one having flowers of that tint. Unfortunately, however, we cannot have all the colours we require in leaves only: hence the necessity of using flowers when wanted. At the same time, by a judicious arrangement of the different coloured foliaged plants, a good effect may be produced, which is retained after the rains of October have destroyed all bloom on the plants having more claim to floral distinction. So much importance do I attach to this, that I regard the *Perilla nankinensis* as the most important addition made to our flower gardens in the last ten years—as it furnishes a colour but indifferently represented in any flower, excepting *Verbena*, and in that, as has been said before, its duration is not to be depended on in dry seasons and situations. To the flower gardener patronising the striped or ribbon style of planting, the *Perilla* and such plants as present a clear distinct colouring, are of the utmost importance; and additions to our stock of such plants will be heartily welcomed, more especially if new colours in that way can be had. The following list of plants which have been used that way here may perhaps be of service to the general reader, to which I append such note as is necessary to make them understood; at the same time, I shall be glad to have what additions others may make to the list, as the one given is far from complete.

Alyssum variegatum.—This is, perhaps, the most useful white plant we have, its numerous blossoms being as white as the plant itself, and improving rather than deteriorating its general effect. Usually it is planted as an edging, but this need not always be so, for in point of height it keeps pace with *Lobelia*, many of the *Verbenas*, and the dwarf class of *Geraniums*. Here we use it for what I would call the stringwork, or embroidery of very large beds, when its uniform growth, requiring no trimming, fits it particularly for such work as cutting up large masses of colour into fanciful patterns in the way we have used it for several years, and for striped borders it is second to no plant that I am acquainted with for general utility.

Arabis variegata.—Dwarf and compact. The foliage being of a creamy yellow, rather than white, yet very beautiful, and being low growing, as hardy as a Daisy, and not particular as to situation, it is valuable as an edging; its appearance in winter as well as in the floral season being good, cheerful, and neat. I believe we have more edgings of this plant than of any other, not even excluding *Box*.

Ageratum mexicanum nanum, or some of its varieties, which however differ so little, that I include them all under one name, is well adapted for a striped border, as supplying a colour not obtained in any thing else. Some judgment is, however, required to place it properly as to light, as it generally overtops *Geraniums*, *Calceolarias*, and such like plants; but it is not the less useful on that account, as tall plants are often wanted as well as dwarf ones: it may therefore be pronounced good.

Cerastium tomentosum.—This seems so well known, and so generally patronised, as to require no further recommendation; and, as a dwarf plant, it approaches nearer to a pure white than anything else I know of; and being of easy culture, hardy, and possessing the property of adapting itself to any situation, it is one of the most popular edging plants of the day.

Variegated Mint or Balm.—I must confess never being partial to this plant, even when our lists of such things were more limited than they are now. It requires more trimming than can always be afforded, and after the middle of August has a dirty grey look. I therefore only mention its name, but recommend something else in its stead, excepting perhaps in such places as nothing else will thrive in.

Cineraria maritima.—Some edgings of this are, at the time I write (the middle of October) the most beautiful things in the garden; and nothing can well exceed its appearance when it really is good, but it is not the most convenient plant to deal with; it is very difficult to have it good in July, and also in October. The propensity it has to flower, in spite of repeated cutting, is such as to give what remaining foliage there may be left a rather sickly unpleasant appearance; this is often the case when old plants are used, and sometimes plants die under the ordeal of stopping, making an unsightly gap. Nevertheless, with spring-struck plants an excellent edging is produced, richer-looking, in respect to the graceful form of its leaves, than that of any similar plant I know of, standing out like portions of frosted silver, contrasting well with turf, or any other herbage it may be in contact with, and in a ribbon-border most look well.

Cineraria amelloides.—Compared with the last-named, this is vastly inferior, but as a compact-growing plant, with a healthy, agreeable foliage, and blue flowers, produced in continuous succession, it is often thought worthy of a place. True, its flowers are never very numerous, that for ordinary bedding purposes it has in most cases succumbed to the *Verbena*; but it may occasionally be grown in the striped border with good effect, its compact habit giving it a claim to distinction which *Verbenas* do not possess when not in flower.

Cuphea strigulosa.—Excepting as a neutral colour this is thought not to be distinct enough for the striped border, otherwise the plant seems well enough adapted that way. I have, however, never used it as such, and fear its claim to honour cannot be regarded at more than "second class."

Chrysanthemum regale flore pleno.—A double yellow *Chrysanthemum*, resembling in foliage some of the annual *Chrysanthemums*, but it is a perennial, and kept through the winter by cuttings. It is a strong grower, and flowers more abundantly perhaps than any plant I know of; certainly no *Geranium*, *Calceolaria* or *Verbena* furnishes so early and so continuous a supply of bloom, and there is no fear of the plants dying. There were expanded blossom early in June; and at the present time (the middle of October) it presents a tolerable good show, and doubtless would have done more so, if the dead flowers had been picked off; while in the middle part of the season, no *Calceolaria* presented such a dense mass of yellow blossom. The plant, however, is tall, quite 2½ feet or more, that it cannot well become a substitute for that popular flower, but it is possible a dwarf variety may be found which hereafter may equal the *Calceolaria* in general utility, and possess the additional qualification of not being affected by the dry weather, which detracts so much from the general merits of the *Calceolaria*.

Calceolaria, yellow.—It is not necessary here to mention specific names, as new varieties are frequently offering themselves; suffice it to say that *C. salviaefolia* is the tallest and *C. aurea floribunda* the dwarfest yellowers that I cultivate. The convenient habit of *C. amplexicaulis* renders it capable of being either dwarf or tall; but somehow I do not admire it much as a plant for a striped border, though excellent in a bed, that I have advised the more shrubby kinds to be used; and both the kinds mentioned, as well as some others, are useful that way when dry weather does not check that growth and formation of flower-buds, so essential to a continuous blooming: this, unfortunately, was the case in 1858, 1859, and again, to a certain extent, this year. Still we cannot do without *Calceolarias*; and if the dry weather in August and early part of September had not checked their growth, I believe they would have been as gay up to the present moment as at any period during the year. *Calceolarias* may, therefore, be regarded as entitled to a prominent place in the list of plants suitable for striped borders.

Calceolarias, Dark or Intermediate.—These do not come out so well as the yellow ones do: therefore I cannot recommend them. *Calceolaria Prince of Orange* blooms abundantly, but its colour is too much of a neutral to tell in a striped border; and the other dark kinds too often present so many blank weeks before flowering and afterwards, that this class can only reckon on the second list of suitable ones.

Geraniums, Plain-leaved Varieties.—The compact habit of most of these renders them very suitable for this work; and as the list includes both tall and dwarf, as well as several colours, many attempts have been made to produce striped borders of *Geraniums* alone, and one of two such borders here are amongst the most successful ones of the season. But one or two remarks seem necessary before describing *Geraniums*—it is to warn planters against using such kinds as have red or purple mark-

ings on the leaves. Many growers regard the fancy appearance these kinds present as a qualification of no ordinary merit; but they look better as potted plants than in a bed, therefore I give the preference to a plain green-leaved variety. A good dark horseshoe marking is not amiss when the plant in other respects is all that is wanted, but it is no better than a plain-leaved one; and more colours than black and green on a leaf only confuse each other, and look dirty and unhealthy.

Such kinds as *Geranium* Punch, *Trentham* Rose, *Tom Thumb*, *Christina*, and others look better than *Compactum*, *Scarlet Globe*, *Cerise Unique*, and others having more or less markings on the leaf, I advise the plain-leaved ones to be selected when convenient to do so; and as this section embraces many colours, habit of plant must be consulted as well as tint. I would certainly not advise many white-flowered ones to be planted, as the best of that class fall short of the variegated ones in giving effect that way. The pink kinds, as *Christina* and others, are, however, indispensable; but I am far from satisfied with *Purple Nosegay*, and hope ere long to see it displaced by one of better habit. As it is, *Geranium lucidum* is certainly as good as *Purple Nosegay*, being more dwarf, and, though its flowers may offend the florist, their numbers compensate the flower gardener.

Geraniums, *Variegated White*.—Of all the plants adapted for the striped border the silver-edged *Geraniums* are the most useful; for, whether in flower or not, their white foliage contrasts so well with adjoining plants that they are invariably favourites. For this purpose I prefer such plants as are of uniform habit, rather upright than spreading, and with leaves that are somewhat cuppy rather than flat, as that shows the edge or white part uppermost; and, looking at them in an almost horizontal direction, this qualification is of much consequence. *Geranium Bijou* is about the best I have in this way of the scarlet-flowered class; but *Geranium Shottisham* Pet as a deep rose is quite as good—nay, even better in its foliage. Flower of the Day is also good; but Brilliant, although, perhaps, the most abundant-blooming *Geranium* we have, is not a good variegated one: but there are several varieties, and every year is adding to the number. *Geranium Alma* is as popular as most *Scarlets*, and as a pink *Silver Queen* or *Annie* is also good; but as foliage is of more consequence than flower it is only to that public attention is directed. *Mangles* Variegated, the best pink of all for a bed, is too rambling for a single line or stripe, although for breadths of 2 feet or more it is very suitable.

Geraniums, *Variegated Yellow*.—Nothing can exceed the *Golden Chain* in this way. *Golden Circle* is stronger-growing; but, like the *Golden Chain*, it loses many of its leaves in September. I think this class is capable of much improvement, and, doubtless, it will receive it in due time. As an edging plant, *Geranium Golden Chain* maintains a sort of regal claim to distinction, which is never denied it, the only difficulty is to get the necessary quantity of it. Taking up and preserving the old plants and propagating from them in spring is the only way.

Geraniums of the Oak-leaved Class.—Shrubland Pet flowers well in a vase, and in a bed of poor soil, and its pretty green foliage looks not amiss without flowers when it is in contrast with other things of a white, yellow, or variegated character; but to those who look for bloom only, I fear it will not be satisfactory, as the flower-stems are short, and when the ground is rich it hardly stands out bold enough to please the fastidious. But with an *Alyssum* on one side of it and *Perilla* on the other, it looks very well.

Dahlia.—Somehow I have never had a good scarlet, white, or yellow, in the dwarf class, although I am aware such kinds exist, there being a good scarlet at the Crystal Palace, but the yellow there is evidently too tall. The best white I have seen this year was in Lincolnshire, and I think was called *alba multiflora nana*. The old *Purple Zelinda* I have had since 1816, and in point of habit it has not been excelled, and I think not equalled. For a central row of the proper height the *Dahlia* is useful and good; but I think the *Dwarf Purple* will succumb to *Perilla*, as in dry seasons there is such a long period with very few flowers, while the *Perilla* is ornamental at all times.

Fuchsia.—Hedges or lines of *Fuchsia Ricartoni* are much admired, but they are not the class of plants that look well in the distance, the flowers being pendant; it is, however, of sturdy growth, and if in front of shrubs forms an excellent background for other things. No white kind that I am aware of possesses qualities so good for bedding purposes as the old *Ricartoni*,

but for the striped border the *Fuchsia* cannot be said to rank in the front class.

Salvia fulgens and *splendens*.—The first-named is a useful plant for a back row, and being about the same height as *Perilla*, might stand behind it. *Salvia splendens* only succeeds in fine seasons, and is late in coming into flower, that for general purposes it is not advisable. The variegated form of *Salvia fulgens* may do very well for a bed, but it is not variegated sufficiently for the foliage to look well without flowers, and as it is, does not look so well as the plain green.

Tinca elegans.—This is a beautifully variegated plant, but better adapted for hanging over the edges of large rustic vases or baskets than keeping in order in the straight line of a striped border; but it may there be trained to order pretty well, and it looks very well, and, being hardy, is a useful plant.

Variegated Grass.—A friend furnished me with a pretty white-leaved Grass from near Liverpool, which makes a pretty good edging. It is, I think, a white form of one of our field Grasses, the seed resembling the crested Dog-tail Grass. As a low-edging plant it is worth growing, differing widely from the old Ribbon Grass of former days.

Pinks.—An edging of double white *Pinks* looks remarkably well around a clump of shrubs, or as an edging facing the turf, and the plant being healthy and tidy looking, it is ornamental at all times; is, is, however, hardly suitable for striped borders.

Lobelia.—A good variety of *Lobelia speciosa* is invaluable everywhere, and there are some pale-coloured kinds also useful; the class of blues, with flower-spikes pointing upwards, are the only kinds worth growing for the striped border, prostrate ones not showing the flower so well; but as a plant furnishing a continuous bloom the *Lobelia* is second to none, and I place it amongst the first class for the purposes here treated on.

Linum flavum.—When in flower this looks well, but it continues only a limited time in that condition, so that I cannot recommend it further than as a plant deserving of notice amongst hardy herbaceous ones.

Perilla nankinensis.—As before stated, I have no hesitation in pronouncing this ornamental plant the greatest acquisition made to the flower garden in the last half dozen years; for, added to a graceful growth and a deep rich bronze-coloured foliage, it is also of that convenient size which may be regarded either tall or dwarf, bearing stopping well. Its services commence in the early part of June, and it looks well up to the time of sharp frost. For the striped border single rows will be sufficient, as its deep rich hue seems to be too powerful when used too freely. As a boundary line of distinction it can hardly be planted in a wrong place, looking well everywhere. If only three species are wanted for a ribbon-border, one of them must be *Perilla*.

Several other plants are occasionally used in the way here treated of. The double white *Everfew* looks well for a time, as also does *Prince's Feather*, *Dielytra spectabilis*, and *Aubretia purpurea*. *Isotoma axillaris* is also used with better effect; but a little practice will enable the inexperienced to know which to reject; and the number of really useful ones is much less than may be supposed. Nevertheless, if any one has any addition to make to the above, I shall be happy to hear of them; and the readers of THE JOURNAL OF HORTICULTURE will also be interested in a matter which is yearly rising into more and more repute. At the same time remember that the qualification for distinction in the striped border is prolonged durability; without these plants are not admissible for this purpose.—J. ROBSON.

(To be continued.)

THE PRESERVATION OF ICE IN STACKS.

I WILL give you my own experience on this matter, having assisted to fill ice-houses of different shapes and in different localities, all erected in the usual style. They do not keep the ice so long as it keeps in the stack. The ground for a stack should be elevated, and in form like a terrace, so that the drainage would be natural. The first cartload should be placed in the centre, and broken small with mallets made for the purpose. They can drive the cart to the side of the stack, and break the ice, and then throw it up on the mass, where it must be broken, if possible, as fine as snow. The large lumps will work down on the sides, and must be thrown up again until the whole is one mass of solid ice, and in the form of a sugarloaf. Ninety-six cartloads will make a nice stack; and, when done as above directed, should be care-

fully covered with dry fern to the depth of 2 feet; then thatched with straw another foot thick. This stack will keep the ice well more than twelve months. When the ice is wanted the stack should be opened on the north side, and the hole filled up again with dry fern and straw.

I have assisted to make a similar stack; the garden engine being at work the whole of the time, until the mass of ice is congealed like a crystal. This will keep well, but not longer than the other way.

I have seen snow-stacks made. These are easily formed, and are useful when we have mild winters. When the snow begins to give, the men should commence rolling until the weight of the mass is heavy to move. They should then make a hole through the centre of the hill, and place a strong pole for an axle, and again commence rolling to save distance of carting. Fifty loads will soon be rolled in this way, and all should be in balls before beginning carting. The stack should be in the form of a cone, and thatched like the stack of ice.

Fern should be used as a cover, because it is a nonconductor of heat, and is the best material for purposes where a uniform temperature is required. Dry bog turf will answer the purpose nearly equally as well, where easily procured; but should also be thatched with straw. Straw will do when neither fern nor bog turf can be procured, but must be double the thickness.—G. HILL.

WORK FOR THE WEEK.

KITCHEN GARDEN.

Cabbage, fill up any vacancies in the autumn plantations; also, make fresh plantations of the autumn sowing if necessary. *Cauliflowers*, those under hand-glasses and in frames must be fully exposed during the present mild weather, or they will button off in the spring. Sow seed on a south border to produce plants to succeed the autumn sowing. *Celery*, sow seed in boxes and place them in heat to produce plants for an early crop. *Garlic* and *Shallots*, where the soil is not wet and stiff should now be planted, if not done in the autumn. Plant in rows 6 inches apart. *Lettuce*, those in frames should have the glasses off them night and day, while the weather is mild. Make a sowing on a south border to succeed the autumn sowing. *Patatoes*, where there is not the convenience of frames or pits, plant on a south border for an early crop. *Rhubarb*, pots may now be placed over the roots and covered with dung or leaves. *Spinach*, a small sowing may be made between the rows of early Peas. *Turnips*, when young ones are wanted early, a sowing should be made on a slight hotbed. Traps should be set in different parts of the garden to catch mice. They now more readily take the baits than they will when there is other food for them.

FLOWER GARDEN.

All new groundwork to be proceeded with as rapidly as possible, so that planting may be completed in good time. The season having been so mild, trees and shrubs will commence growing much earlier than usual, such as are intended for removal should be taken up carefully and laid in by the heels till wanted. This will act as a check upon their early growth. The planting of shrubs is sometimes postponed from the autumn when it would be certain of being followed with more favourable results. However, it is sometimes unavoidable, but whenever the planting of shrubs takes place, it is advisable that they should be planted at such a distance from the walks and from each other that they would not interfere with either for several years. The mode of planting shrubberies adopted by some persons is very defective, as there is no attempt at arrangement, and when this is neglected at the time of planting, no after-thinning or removing, short of taking up and replanting the whole of the shrubs, will give them the effect that they would otherwise produce in such a situation. In planting shrubberies, those plants which are intended to remain permanently should be first planted, and the intervening spaces to be filled up with whatever plants may be at hand, and as they encroach upon the permanent plants they should be removed. Shrubs will not then require pruning, which, with digging about their roots, should be avoided as much as possible, if handsome specimens well feathered to the ground are the objects to be desired. The turning of walks may now be accomplished, and new gravel provided where necessary. All grass lawns and margins to have a thorough cleaning and rolling at an early opportunity.

FRUIT GARDEN.

Where nets or bunting cannot be procured for protecting the blossom of Peaches and Apricots, suspend from the top of the wall to the bottom of the trees a quantity of straw or hay ropes made with a few projecting loose straws. Dry fern or spruce branches may be nailed over the branches of the trees with advantage. Continue pruning and nailing as directed before.

STOVE.

Stove plants in general will now require an increased amount of atmospheric moisture with a slight advance in heat. Begin to repot Orchids, taking them in succession as they come into growth. Keep the plants well elevated and use plenty of charcoal in lumps of good size, fastening the whole that the plant may not easily be disturbed. Moss pegged on the top gives a good finish, and is useful for retaining moisture. When there is any fear of a deficiency in the atmosphere, syringe plants on blocks occasionally, the temperature to be 60° by night, 65° by day, rising to 70° on sunny afternoons.

GREENHOUSE AND CONSERVATORY.

Return all plants from the conservatory to the stove or greenhouse as they go out of bloom, and such plants as *Euphorbia jacquinioides*, *Poinsettia pulcherrima*, and other such plants which have done blooming, may be set aside and kept comparatively dry for a time. It may, perhaps, be necessary to top-dress or renew the soil around some of the borders; if such is the case let it be done before the end of the month, and give the plants a good soaking of clear weak manure water at the same time. Orange trees in tubs are liable to be affected by a black fungus on the leaves, having the appearance of soot. This should at all times be thoroughly cleaned off, and is easily and effectually removed with a sponge and some warm soapuds and some sulphur mixed with it.

FORCING-PIT.

Continue to introduce Roses, bulbs, Lilacs, Sweet Briars, &c., for succession. Fumigate whenever green fly appears, and syringe the plants whenever the weather is favourable.

PITS AND FRAMES.

Examine the stores of half-hardy plants. Amongst them, in the majority of cases, will be found blanks, and some of the best store-pots, or established plants of the same, should be introduced to heat in order to procure early cuttings. No delay should take place in this matter, for much of the success in massing depends on having a stock of forward well-established and hardy plants at bedding-out time. W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

THOROUGHLY cleaned and surface-gravelled walks when we could get at them, so as to forward labour. Cut and put more Ash-leaved Kidney Potatoes into a mild heat, to spring them before planting under protection, or out of doors when the soil is dry and friable, having found that in heavy soil little is gained by planting either in autumn or in winter. Sowed Peas, such as Sangster's No. 1, one row; Dickson's Favourite, two rows; Veitch's Perfection, one row; Jeyes' Conqueror, or Ne Plus Ultra, two rows. Sowed also in turf to be placed in Peach-house Sangster's No. 1, to be helped forward, and then transplanted for the first crop out of doors. We like boxes better; but all are full. Sowed Mazagan and Long-pod Beans out of doors, and some in turf for transplanting, and a score of No. 32-pots, four Beans in a pot. These when grown will be transferred to nine-inch pots, and placed in a late orchard-house to give a few dishes before we can get them in the open air. Tom Thumb Peas, sown in orchard-house, with plenty of air on, are now about 1 inch in height, and will come in a week or two before those in the open air. We have some 30-inch pots considerably forwarder, and these by-and-by being transferred to nine-inch pots will be kept a little warmer, to give us an early gathering. Sowed a score more of six-inch pots of the same dwarf variety, and placed them in heat, so as to be hardened off afterwards, and thus join the earliest before the rows in the orchard-house come in. Earthed-up Dwarf Kidney Beans in pots, and transplanted more from boxes in which they had been sown thickly. Gathered, or rather pulled, Radishes, and gave plenty of air to those remaining. Added a lining of hot leaves to Asparagus-bed in frame, which has produced abun-

dantly; the same frame supplying Green Mint, Fennel, Sorrel, Tarragon, &c. Pricked up the soil among Lettuces, Cauliflowers, &c., and earthed-up the forwardest Potatoes in pots, and transplanted more. In 12-inch pots use three sets, after being sprung, and if these sets had been rooted in small three-inch or four-inch pots previously, they will grow less vigorously, and yield their roots rather sooner. The having such things in pots enables a person to move them easily, and even give a little bottom heat when necessary. The last succession of ours is generally set out under the protection of Spruce trees, where they receive enough of light to ripen the stems, whilst the branches above them prevent the frost touching them to any extent. Sowed round Spinach between the Peas, and some Radishes, to let them take their chance without any protection. Turned over soil intended for Onions, as more depends on having the soil in good order, than in sowing extra early. Made preparations for raising and fresh boxing a main walk in the kitchen garden; the Box being strong and nice now, but the walk being much too low, as the soil and dung introduced to the quarters for many years have raised them considerably, and the walk in damp weather cannot be kept so dry as is desirable.

FRUIT GARDEN.

Kept a mild heat in the first house of Peaches and Vines. Dusted Strawberry blossoms with a feather that were in bloom; in these dull days, partly on account of the dull weather, allowed none to stand in saucers, but in some cases put a little moss on the shelves. The leaves of some that were inclined to grow rather luxuriant were bent down over the rim of the pots. They will thus stand a good bend without injury, and at an early period more strength is thus apt to be thrown into the flower-truss. I notice that this season the flower-trusses take more time in coming than usual. Made preparations for pruning and washing Apricots and Peach trees, as well as harder fruits. Broke the dung a little among Strawberries, and sowed Melons on the 5th, because I saw that I could not have a bed or beds for them under a month at any rate, and few things like less to be cribbed and knocked about before final planting than Melons do.

FLOWER DEPARTMENT.

Roses in pots should now be pruned so as to admit of their being slowly forced, or brought on in a cool temperature. The plants should remain cool a few days after being pruned. The prunings, if of valuable kinds, may be struck or grafted. For grafting it is as well that the stocks be established in small pots, and then after being tied on as low down as possible, it will be as well to keep them close in a glass case for a week, and then to give a little bottom heat to accelerate the junction of stock and scion. Roses out of doors may mostly now be pruned, except the Teas and the tenderest Chinas and hybrids. This month is also a good time to move Roses; in the north it will be as well to defer doing so a little longer. There seems less danger in the moving just as the buds are starting. Potted-off some of the best Roses that were inserted as cuttings in autumn, and gave them the benefit of a mild bottom heat to give them a start. The whole family of Gladioli, if not planted at once, might be laid thickly in soil, and be moved as wanted or as the ground gets ready for them. In the open ground herbaceous plants may be regulated, large heads lessened, and a little rich compost placed about those that soon exhaust the soil. We are glad to see that these old favourites are getting fashionable again; for mixed banks, or beds of herbaceous plants, are still fine things. Even in grouped flower-beds a few beds of elegant herbaceous plants are not only beautiful by contrast, but would often do much to do away with the level monotonous lumpishness of mere gorgeousness of colouring. Did I get near Mr. Weaver I might do something more with those large specimens than go on a journey of note-comparing. Placed Fuchsias, large ones and smaller ones, in the first vineery after pruning them; and as the house averages from 50° to 55°, as soon as the plants break will shake most of the soil from them and fresh pot, and syringe in sunny days until the roots are taking hold of the new soil. Cleared the Peach-house of bedding plants except some Alma Geraniums and other variegated ones below the trellis, so that they may get a lift of extra heat; and filled the shelves with Strawberry plants, dressing them as previously described. Gave all the air possible in mild days to keep bedding plants, as Calceolarias, &c., back, as soon now for the next three months will be all the difficulty. Got a good clamp of tree leaves together to heat well, and help

to startle the slugs out of them, so as to be in readiness to commence propagating Verbenas, Petunias, &c. We find there is nothing gained by beginning too soon, unless there be a new thing, much of which is wanted, or there is great room for keeping them afterwards; as, often when turned-out to help themselves, as they can be too early, the labour is next to lost. All Dahlias desirable to multiply and get strong plants of before the middle of May, we have moved from a shed and put into a slight hotbed; the rest will be placed on the floor of a vinery or a Peach-house. Plant-houses general routine.—R. F.

TRADE LISTS RECEIVED.

Barr & Sugden's Guide to the Flower Garden, &c.—This is in reality the title to *Barr & Sugden's Spring Seed Catalogue*. It is a bulky pamphlet of 116 pages, illustrated with four woodcuts, and supplied with a visitor's hand-map of London. It is very well got up, and contains a great deal of information, both of a cultural and descriptive kind.

E. G. Henderson's Seed List, 1862.—This also forms a pamphlet of 96 pages, and it, too, is one of those carefully-prepared catalogues which contain a great deal of useful information.

A Select Catalogue of Flower, Vegetable, and Agricultural Seeds, &c., by B. S. Williams, Holloway, N.—This is a full and useful catalogue, consisting of a select and very choice list of all the different kinds of garden, flower, and agricultural seeds.

Among the other catalogues we have received we have those of *Messrs. Catbush & Son, of Highgate*; *Messrs. Stuart & Mein, of Kelso, N.B.*, both seed and nursery lists; *Mr. Stephen Brown, Sudbury, seeds*; *Messrs. Smith & Simons, Argyle Arcade, Glasgow, seeds*.

TO CORRESPONDENTS.

** We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely to The Editors of the "Journal of Horticulture, &c.," 162, Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

We cannot reply privately to any communication unless under very special circumstances.

CLIMBERS FOR BACK WALL OF GREENHOUSE (R. M. S.).—With a stage 18 inches or 24 inches from the ground, and the wall only 8 feet high, we would plant the climbers in the border, and then train them along below the apex, and spray-prune every year, so that the flowering shoots would hang down in summer; and we would plant *Passiflora carolinæ* at one end, *Passiflora corollæ racemosa* at the other, and *Mandevilla suaveolens* in the middle.

SCABLET GERANIUMS DISEASED (A Lacer of Flowers).—Your Geraniums are suffering from cold and damp. A warmer atmosphere and a little drier will make them all right—not those that's gone; but after all these are removed, and the whole of the affected leaves taken away, there will be enough of strength in the old stems to throw out healthy foliage. We suspect that in the temperature in which these plants were placed, the atmosphere should have been drier. Old plants, as repeatedly stated, will bear rough treatment; young plants will not stand such roughness.

GREENHOUSE BORDER (J. R. W.).—Fifteen inches will be wide enough for the plants you name.

GERANIUM LEAVES DRY-CAYED (W. F.).—Your Geranium leaves had every appearance of being exposed to a bright sun when the leaves were moist, and the roots dry; we could not see thrips, but we could see where they had been. If you find any of these, you had better smoke the plants with strong tobacco, and be sure the smoke is cold; and next day lay each plant down in a shed, and syringe it well, with water about 65°, and keep the plants shaded until the leaves are dry. The condensed moisture from the glass, with a little inattention to air-giving, would produce scalding; but we fear you have also thrips. The soil is all right.

BACK WALL OF A GREENHOUSE (Kate).—The white will be apt to scorch the trees by reflected heat, as well as to burn the eyes by reflected light. You had better add lampblack to the whitewash, enough to give it a darker or greyish tinge. We presume the lark wall is to have fruit on it. If your Vines are, say, 1 foot higher than the roof you wish to train them to, you may cut off as much as that; but if you do not wish the Vines to bear and they reach the roof below the roof then one bud will be enough to leave at the root, and all the rest downwards must be removed. We are not sure if this is what you mean. The smoke-chimney from the case must go directly out of the house, unless you can run it into a chimney or flue.

SOWING SOLANUM CASIBARIENSE (H. F.).—Sow the seeds of the Solanum any time between this and April in a little bottom hole. Pick off the seedlings when up, and then pot singly first in three and then in five-inch pots and that will give you nice flowering plants.

CHEEBIE'S FALLING IMMATURED (J. C.).—The trees might be moved with care, but we see no reason why they should not do well where they are. As regards water, we would not move them now, but as soon as the trees are in bloom make holes in the walk, and give a good soaking with water not less than 60° and, if it contains a little soil or guano all the better. If the walk is very deep we would also take it out, fill with fresh, good, rich soil, and replace the soil of the front with an inch or 6 inches. Try one or both methods before lifting, and let us know the result.

POINCIANA PUCHERRIMA CULTURE (J. B.).—The Poinciana is a low spiny shrub from the East Indies, and wants a medium temperature in winter of 60°, and from 70° to 80° to bring it into vigorous growth and bloom in spring and summer. When done flowering clean and prune a little, and keep the plants in for a few weeks, but as soon as the winter wood has formed and moisture until the end of September, when for ripening the wood the plant should have all the light possible, and water be gradually curtailed. It is easiest propagated by seeds, which should be steeped in hot water before sowing; also by cuttings in sand under a bell-glass. Small air-shoots 2 inches in length and a heel of the older wood attached are best. Place these in a sweet hotbed, and give air at night to prevent damping. Fibry loam and heath soil, with a little leaf mould and sand, will do for it well. Moisture as above alluded to, only use the syringe freely all summer, unless when in bloom, as then it would injure the long stamens that stand beyond the flower.

LAYERING CARNATIONS (Idem).—Choose the shoot, strip off three or four of the lower leaves, fix on a joint most suitable, insert a sharp knife just behind it and let it go halfway through the shoot, then turn the knife, and run it up the middle of the shoot until you come to the next joint. A space closed the tongue, consisting of half the stem between the joints—the lower end is now layered and covered with earth; and when roots are protruded from the tongue just as it is cut away and turns a plant.

VARIETIES (E. M. M.).—The leaf enclosed seems to be that of the Nettle-leaved Birch, a d-former variety of the common Birch. Dumont's Leaf Powder can be obtained in the gutta percha balls at many chemists in London. You may have the numbers you require by forwarding four stamps for each with your direction.

GRASS SEEDS (H. G. C.).—On your third of an acre, gravelly soil, sow at the end of March 2 lbs. Crested Dog-tail, 1 lb. Hardish Fescue, 1 lb. Evergreen Meadow Grass, 3 lbs. White Clover, and 1 lb. Small Yellow Clover.

HEATING A SMALL PIT (A Subscriber).—A small iron stove, or a small brick Aroost's stove, made so as to be red from the outside, and a metal pipe to be attached to the boiler, and the pipe to be set up out of your pit 7 feet by 9 feet. To force a little, a small fire round three sides, or four, would be the simplest alike for bottom or top heat; or a small boiler might be fixed, and pipes taken from it. The difficulty is, that the furnace for such a place would be for one four times the size.

GREENHOUSE SPANS (A This-year's Subscriber).—If you look back to No. 105, you will see that the plants of London are not so quick as you will find all the minute you require. This is a bad time to make Mushroom spawn. You had better purchase half a bushel or what you want, and start fair for making in spring and summer. The chief circumstance against you is the difficulty of getting dung, &c., dried now.

PLANTS FOR WALL OF A LEAN-TO HOUSE (Augustus).—You do not tell us how your house is furnished, nor its length. If a winter display and green at all times nothing would beat Camellias. For late winter and early spring, fine foliage and masses of flower, and free growth, filling a space quickly, few things would look handsomer than *Acacia grandiflora*, *Chrysanthenum*, and *Yucca*. The *Acacia* arnuta would make a good green and thick cover to the cold and garden in winter. For climbing plants to make a great show in summer we would place a *Strophantia* at the warm end, a *Habrohamnus elegans* in the middle, and a *Mandevilla suaveolens* at the coolest end. For baskets we would place *Lobelia gracilis*, *Maurandia*, *Barclayana*, *Lophosiphium* of sorts, *Tropaeolum* of sorts, *Saxifraga sarmentosa*, *Tradescantia zebrina*, *Torricia asiatica*, *Turnbergias Ferns*, *Adiantums*, &c.

FERNS (Augustus).—You will see announced very shortly what will meet your suggestion, but we are obliged all the same.

PRESERVING STAKES (G. B.).—No treatment preserves stakes from decaying in the ground so effectually as thoroughly charring their outside. If you can coal tar, melt some fat with it and apply it hot; but you had better shorten your stakes a little, and then char them. The best thing for you is of garden rubbish kindled in the open air. You then need not use tar.

PRUNING PASSION-FLOWERS (H. B.).—Every well-ripened bud on last year's wood of the Passion-Flowers is capable of producing a flowering shoot next season. Buds on imperfectly ripened wood will produce only shoots. The wood first made is likely to be the best ripened; and therefore you may leave just as much of last year's wood as you think you can find room for shoots from it next summer, keeping in mind that if you leave much and grow in such a box, a number of buds will not be likely to break or push.

HYBRID PERPETUAL ROSES IN POTS (Idem).—If the Roses are very good and you can give them the room, we would shift them from the 60s to 48-pots, and turn them out at the end of March. If you have not the room you can turn them out in well-paired soil, and stick a few evergreen boughs about them for a month or six weeks.

OLD ASPARAGUS PLANTS REMOVED (Amateur).—As so few heads come up we fear that they will not do much better this season. You could satisfy yourself by examining the plants and seeing if the buds are sound or not. Few plants require more trouble and care in moving than old Asparagus, and many it is worth your while to try to save. The best thing to do when the plants show an inch above the ground. If you have made the beds well that is so far good; but unless there is a sign of the old plants doing well, we would advise to fresh plant with one or two-year-old plants this spring, just when the plants begin to move, and cover between the rows with a few inches of manure. If the plants are to be saved you should have selected the youngest and freshest ones, not the largest.

AEACANIA INJURED BY FROST (D. L. D.).—Cut off the dead points of the branches down to the live part. Do not leave any of the dead wood. The end of next month will be time enough to do so.

FLOWER-GARDEN DESIGNS (L. M. L.).—For a circular plan take the centre of that we published in No. 638.

TAN TO GOOSEBERRY AND CURRANT TREES (J. M.).—Fork over the surface of the soil, and put the tan on during the present month.

VARIETIES (E. M. M.).—T at blanched shoots of Geraniums could not be rooted or be made useful if they could was one of the earliest questions which were settled in our pages. Your Geranium which so spotted is called *Crisp* and we do not know of any not being so. As to the white shoots, they come in that kind, in all kinds of composts, and in no composts. Variegated Ivy-leaved Geraniums, as far as we know and recollect, have never been a desideratum. They have been in cultivation much longer than geraniums, and are mentioned in almost every one of our volumes. Your second question should have been sent to the editors of the works referred to; and to your third question, we reply, Never speculate on hybrid plants till they come into bloom.

CATS—ROSES (S. C. R.).—Catch the cats in a drop trap, put the trap into a bucket of water, dig a hole, empty the contents of the trap into that hole with a bucket, and so on until you return the earth into the hole. If any one asks you if we have seen his or her cat, you can then reply truthfully in the negative. The best white climbing Rose is *Eldicet perpetuelle*; the best red, *Gracilis*; and the best pink, *Indica major*.

NAMES OF CONIFERS (P. O. O.).—Your specimens are—No. 1, *Picea nobilis*; No. 2 one of the small varieties of *Picea pectinata*.

PEARS AND CHEEBIE'S IN POTS (D. B.).—As you propose turning these out of your orchard-house to make more room for the Peaches, we recommend you to plant the pears in a border beneath a south wall, and stretch fifty or even more from the wall down to the surface of the border like a lean-to. We should not be satisfied with merely covering the tops.

GRAPE (P.).—Your plants of Buckland Sweetwater are not yet strong enough. No doubt they will fruit next year. The *Jura* Frontignan is *Muscot Noir* de *Jura*, and has a resemblance to the *Black Frontignan*, we think.

HYACINTH BELLS (Ellen).—After blooming in water-glasses they will not produce flowers the next year. They have had no opportunity of storing up the materials for such growth. If they had been bloomed in pots of earth it would have been otherwise. When you take the bulbs out of the water-glasses, plant them without breaking the roots in holes in a sheltered border, filling the holes with liquid mud made of the soil and again produce flowers.

RIDGE CUCUMBER (W. Whiteley).—No Cucumber is better for growing on ridges than the old Long Prickly.

PRICE OF WOODWORK (G. B.).—We do not know the prices of such articles, and as prices vary in every locality, we should mislead you if we stated any. Apply to two or three makers of such articles in your own neighbourhood for their estimates.

GREENHOUSE PLANTS FROM SEED (A Constant Reader).—All the plants you name come true from seed, if you obtain true seed.

VARIETIES (Westmorlander).—If *Ulex* nana is kept regularly clipped, we have no reason to think that it will not keep thick and green at the bottom. It may make a low edging as Loudon says, but we never saw it used for the purpose. Messrs. Carter, seedsmen, Holborn, perhaps could supply you with seed. Dr. Busch Fear tree will not be so good as you think. Pyridinuous acid is only vinegar (acetic acid), obtained by charring wood in close retorts. It is very pungent, and has a strong smell of burnt wood. We have no faith in its power of preserving wood.

NAMES OF PLANTS.—* In sending plants for naming our correspondents should remember that, as a general rule, garden varieties, especially if they are new, are not to be named. He has the *Epacris*, *Azalea*, and still less the subjects more decidedly ranking as florists' flowers, cannot be named satisfactorily. We have not at our desk the means of identifying such as these; and we cannot undertake a daily visit to some nursery in order to do what our correspondents might generally do easily enough for themselves—i. e., come (A Young Gardener).—*Erica* hycn lis, and one of the deep red varieties of *Epacris* imbrata, which you can identify at some nursery. (*J. D., Forfarshire*)—1, *Polypodium vulgare*; 2, *Veronica hesebiana*.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

POULTRY, &c., SHOWS.

MARCH 1st. HALIFAX. Sec., Mr. J. W. Thompson, Southwram, near Halifax. Entries close February 20th.

MAY 14th and 15th. TAUNTON and SOMERSET. Sec., Charles Ballance, Esq., Taunton.

MAY 27th, 28th and 29th. BATH AND WEST OF ENGLAND (City of Wells). Sec., Messrs. Pitham, Esq., Manor House, Taunton. Entries close May 1. JUNE 4th and 5th. BEVERLEY AND EAST RIDING. Sec., Mr. Harry Adams.

LIVERPOOL POULTRY AND PIGEON SHOW.

FEBRUARY 5TH AND 6TH.

It is a true remark that the season of poultry shows would be felt to be incomplete without the recurrence of that one which has just taken place for the eighth time in the town of Liverpool, after the Birmingham and Crystal Palace Exhibitions are over; and the excitement connected with "winning and losing" at these two great collections has somewhat cooled down. The thoughts of amateurs in all parts of the kingdom turn naturally towards Liverpool as the last place of the season to which they must send their birds, either to crown by success former triumphs, or to submit to defeat with the inward resolve (as our grandmothers used to teach us) to "do better for the time to come."

We reckon the Liverpool Show amongst the number of our most valued occasions of competition, and that on many accounts. The prizes offered are liberal. The arrangements are always carried out by well-qualified and energetic men, and leave nothing to desire for the comfort of the birds or the satisfaction of exhibitors. In a show numbering more than five hundred pens, the duties devolving upon the Hon. Sec. could neither be few nor trivial; therefore it is but bare justice to remark that Mr. Lawrence seemed to be all but ubiquitous in his movements, and unremitting in his endeavours to please and satisfy his numerous friends. The awards appeared to carry the conviction of all parties with them; and, during the time that we remained in the building, we heard no complaints, and met with no dissatisfaction. Messrs. Lucas's repository (where the Show annually takes place), is well adapted for such a purpose; the light is good, the building lofty, the situation central. The pens in which the birds are shown belong to the Society; and, as the sides are fixed at optional distances on flat boards, we would respectfully urge that more space should be allowed for each pen—3 feet are not too much in length, especially for the larger varieties, such as Cochins and Dorkings; very little more than 2 feet in length was apportioned to each pen, evidently causing inconvenience to some of the birds. We pointed this out to Mr. Lawrence, who at once admitted its desirableness, and said it should be taken into consideration on a future occasion.

There is one point connected with the Show which has just been held, and which deserves from us especial notice—viz., that though this is the eighth poultry show held in the town of Liverpool, it is the first which has been judged exclusively by amateurs. We are aware there exists a difference of opinion on this question amongst managers and committee men, and we have not a word to say against the integrity of those gentlemen who, although dealers, are frequently engaged to act officially in awarding the prizes. Nevertheless, no better locality could have been selected than Liverpool to try the experiment; and we are happy to learn that the result has fully answered the expectation of the Liverpool Committee, whether regard be had to the correctness of the awards or to the expressed satisfaction of the exhibitors with the new system of judging inaugurated by them this year.

If there is one breed in which Liverpool excels more than another, it is the noble English breed of Game fowls, and no severer test of accurate judging could be desired than that which fell to the lot of the three gentlemen engaged to award the prizes in these classes, which were all well filled, and with birds far beyond the average of merit; yet the result of our inquiries from the Committee failed to elicit more than one instance in which the owner of one of the successful Single Game Cocks considered (to use his own expression) that his "hannimal" ought to have stood one step higher—viz., exchanged places with the "hannimal" above him. Beyond this we were informed by Mr. Lawrence that no complaint whatever had been made to the Committee.

We now hasten to a rapid survey of the classes as they appeared in the catalogue, and a few brief remarks upon the successful pens.

Spanish headed the list, and brought together fifteen pens, most of which contained birds which proved to what a point of excellence this handsome breed has been brought by careful breeding and perseverance. Miss Rake bore away the palm, followed by Messrs. Hyde and Shorthose as second and third. We much admired the cockerel in Mr. Brown's pen, his comb was perfection, but the pullets were small. Capt. Hornby's pen was highly commended. The Minorcas (or Spanish Red-faced as they were called), require no notice—they were indifferent.

Coloured *Dorkings* were numerous, counting twenty pens, and most of them of good quality. Capt. Hornby was first, Mr. Potts second, and Lady Louisa Thynne third. Silver Greys were better than we usually see them, though the perfect black breast was deficient in some of the pens. Lady Julia Cornwallis took the lead, closely followed by Mr. Cargey and the Rev. J. F. Newton.

The *Buff Cochins*, though only mustering ten pens, were the best lot we have seen for a long time. Surely the days of Cochins cannot be gone by if such birds as we saw at Liverpool are still forthcoming for our shows. Mr. Stretch maintained his reputation by winning first and third; Miss Musgrave second. Every pen was meritorious. Partridge Cochins were equally good; and Mr. Stretch was again first and third, while Mr. Felton secured the second.

The *Hamburghs* of all kinds came out in goodly array; but the Silver-pencilled failed to remind us of the good old times when Mr. Archer carried all before him in this breed. The first prizes went to Messrs. Munn, Martin, Brook, and Fielding.

The *Game* classes, however, were the chief attraction, every kind being well represented, as appears by the following numbers—Black-breasted Reds, 23 pens; Brown Reds, 18 pens; Duck-wings and other varieties, 22 pens. In Black Reds the first and second prizes remained in Liverpool, with the well-known names of Hindson and Moss. Mr. Stubbs third. In Brown Reds Mr. Moss secured first and second, Mr. Fletcher third. In Duckwings all three prizes were won by Liverpool amateurs, Mr. Hindson and Mr. Worrall dividing them. In the "other varieties of Game" Mr. Fletcher took first and third; Mr. Wood second. Our limited space forbids us to notice the other pens in each class, which were highly commended. Suffice it to say they were all worthy of prizes, and would have won them had the competition been less severe.

The *Game Bantams* came out well, and filled eighteen pens. The names of Messrs. Bayly, Cragg, and Whitwell will be looked for here, and found in the order indicated as first, second, and third. The other varieties of Bantams were few in number, and, excepting the prize birds, not noticeable as to merit.

In *Rouen Ducks* we were pleased to meet with an old name in connection with this breed, and to find it also in the fore front of the competition. We need scarcely say we refer to Mr. Worrall, who won first and second, leaving only the third for Mr. Fowler. We had heard with regret that Mr. Worrall had given up this breed, but were glad to find ourselves mistaken, and hope to hear more of this gentleman's exploits with the breed for which he was once so famous. In *Aylesburys* Mr. Fowler made a clean sweep; but this is a tale our friends have now become accustomed to hear. In the "other variety" of Ducks, the prizes went to Blacks, Calls, and Muscovys. The first to Mr. Jessop, to a pen both small and pure in colour; the Calls were Mr. Bayly's; and the Muscovys Mrs. Bay's.

The other breeds were shown in Sweepstake Classes, of which we have before expressed our opinion—viz., that this plan does not answer, except for single cocks. With the exception of Mrs. Pettat's Polands and Mrs. Fookes's White Dorkings, there was nothing exhibited of any merit requiring notice at our hands. The *Cochin chickens* were a good class; the prizes were divided between Messrs. Felton, Tomlinson, Stretch, and Musgrave.

Two prizes were awarded for *Single Spanish Cocks*, Miss Rake's birds distancing all rivals. Twelve birds were entered in this class, and many of them were first-class specimens. In *Dorking Cocks*, the birds shown by Lady Julia Cornwallis and Lady Louisa Thynne were perfection. They won first and second, six birds competing. The *Single Cochin Cocks* were fully up to the mark, and showed remarkably well in size, condition, and feather—eighteen birds, and all meritorious, made a good display. Miss Musgrave carried off two of the prizes, the others went to Messrs. Stretch and Cartwright.

The *Bantam Cocks* came out in force, fifteen little fellows doing their best to attract attention, and requesting to know "the reason why" they had been sentenced to "solitary confinement." The three prizes were secured by Messrs. Cumm, Cragg, and Bayly in the order indicated.

We come now, and lastly, to the grand feature of the Exhibition—we mean the classes for *Game Cocks* and *Cockerels*; twenty-four of the former, and twenty-two of the latter. We must refer our readers to the prize list for the fortunate prize-takers in these two classes. We certainly never saw a collection of our favourite birds so thoroughly up to the mark in every point of this really splendid and peculiarly English breed. They were judiciously preserved for the top tier of pens, and showed to great advantage. We will only remark that Mr. Hindson's Black Red cock and Mr. Moss' Brown Red cockerel were, in our estimation, the *beau ideal* of perfection in their respective classes.

In conclusion, we heartily congratulate our friends at Liverpool on the result of this year's Exhibition, and hope they will be encouraged by it to still greater efforts at their next merry meeting, and when it takes place "may we be there to see."

SPANISH (White-faced).—First, Miss M. L. Rake, Brandon Hill, Bristol. Second, S. B. Hyde, Ashton-under-Lyne. Third, J. Shorthose, Newcastle-upon-Tyne. Highly Commended, Capt. Hornby, Knowley, Prescott; E. Brown, St. Philip's Road, Sheffield. Commended, H. Lane, Bristol; Miss M. L. Rake.

SPANISH (Red-faced).—Second, Miss M. L. Rake, Bristol. Third, J. Hindson, Barton House, Everton. First withfield.

DORKINGS (Coloured).—First, Capt. Hornby, Prescott. Second, A. Potts,

Hoole Hall, Chester. Third, Lady L. Thynne, Muntham Court, Worthing. Highly Commended, H. W. B. Ferwick, Helmsley, Yorkshire; C. H. Wakefield, Malvern, Wells; Lady L. Thynne. Commended, A. Potts; W. Copple, Eccleston, Prescot.

DORINGS (Silver Grey).—First, Lady J. Cornwallis, Linton Park, Staplehurst. Second, G. Cargey, Stone, Staffordshire. Third, Rev. J. F. Newton, Yorkshire. Highly Commended, Capt. Hornby, Prescot.

COCHIN-CHINAS (Cinnamon and Buff).—First and Third, T. Stretch, Boole. Second, Miss V. W. Musgrove, Angli, near Ormskirk. Highly Commended, Mrs. H. Fookes, Whitchurch, Blanford, Dorset; C. Felton, Boole. (An extraordinary good class.)

COCHIN-CHINAS (Partridge and Grouse).—First and Third, T. Stretch, Boole. Second, C. Felton, Birmingham. Highly Commended, Miss V. W. Musgrove, Angli; P. Cartwright, Oswestry. Commended, E. Smith, Manchester; J. Bolton, Birmingham.

HAMBURGS (Golden-pencilled).—First, J. Mann, Stacksteads, near Manchester. Second, Carter & Vainant, Poulton-le-Fylde. Third, J. Lindsay, Stewarton, Argyll & Co. Highly Commended, J. Mann. Commended, T. Shaw, Eickham, Laneshire; A. Nuttall, Manchester.

HAMBUROIS (Silver-pencilled).—First, J. Martin, Claines, Worcester. Second, W. Wood, Walkley, Sheffield. Third, W. H. Kerr, Worcester.

HAMBUROIS (Golden-spangled).—First, G. Brook, Huddersfield. Second, W. Worrall, Knotty Ash, Liverpool. Third, H. W. B. Ferwick, Helmsley, Yorkshire.

HAMBUROIS (Silver-spangled).—First, J. Fielding, Rossendale, near Manchester. Second, Lady J. Cornwallis, Staplehurst. Third, J. Terry, Mill End, Rossendale. Highly Commended, Lady J. Cornwallis; H. Carter, Upton, Holmfirth; J. Fielding. Commended, T. Dale, Middlewich, Cheshire.

GAME (Black-breasted Reds).—First, J. Hindson, Everton. Second, G. W. Moss, the Beach, Algbath. Third, J. Stubbs, Stafford. Highly Commended, G. W. Moss; J. N. Grimshaw, Burnley; E. Archer, Malvern; J. Keabing, North Cadis, Herefordshire; H. W. B. Ferwick, Liverpool. Commended, R. Woods, Workop, Notts; C. Chaloner, Workop; D. Ashworth, Halifax.

GAME (Brown Reds).—First and Second, G. W. Moss, the Beach, Algbath. Third, J. Fletcher, Manchester. Highly Commended, J. Wood, Mat House, Wigan; J. Hartley, Crompton House, T. West, Eccleston, St. Helens; F. Worrall, Liverpool.

GAME (Duckings and other Greys).—First and Second, J. Hindson, Everton. Third, H. Worrall, West Derby. Highly Commended, J. Fletcher, Manchester; G. Crofts, Birmingham. Commended, T. Carless, Hovingham, Notts.

GAME (any other varieties).—First and Third, J. Fletcher, Manchester. Second, W. Wood, Walkley, Sheffield. Highly Commended, J. E. Weeks, Worcester. Commended, T. P. Wood, jun., Chesterfield.

BANTAMS (Game).—First, T. H. D. Bayly, Biggleswade, Beds. Second, J. Craig, Kendall. Third, G. C. Whitwell, Kendal. Highly Commended, W. L. S. Allen, Glancore, county Cork; R. H. Postans, Brentwood, Essex; W. Silvester, Sheffield; J. Camb, Southwell, Notts.

BANTAMS (Gold and Silver-laced).—First, T. H. D. Bayly, Biggleswade, Beds. Second, S. Shaw, Stainland. Commended, G. Maples, jun., Wavertree.

BANTAMS (any other varieties).—First and Second, E. Hutton, Pulsey, Leeds. Highly Commended, Mrs. W. Worrall, Knotty Ash, Liverpool.

DUCKS (Highland).—First, T. H. D. Bayly, Biggleswade, Beds.

DUCKS (any other varieties).—First and Second, H. Worrall, West Derby. Third, J. K. Fowler, Aylesbury. Highly Commended, E. Longton, Liverpool; P. Pilgrim, Nottingham; S. Shaw, Stainland.

DUCKS (Aylesbury).—First, Second, and Third, J. K. Fowler, Aylesbury. Highly Commended, H. Holmes, Preston.

DUCKS.—First, J. R. Jessop, Hull. Second, T. H. D. Bayly, Biggleswade, Beds. Third, M. S. Bley, Gregory's Bank, Worcester. Highly Commended, F. W. Earle, Prescot. Commended, J. Martin, Claines, Worcester; Capt. G. R. Edgell, Exeter.

ANDALUSIENS.—Prize, Mrs. Bley, Gregory's Bank, Worcester.

DORINGS (White).—Prize, Mrs. H. Fookes, Blanford, Dorset.

BRAMA POOTERS.—Prize, J. K. Fowler, Aylesbury.

POLANDS (Golden-spangled).—Prize, Mrs. Pettat, Basingstoke, Hampshire.

POLANDS (Silver-spangled).—Prize, Mrs. Bley, Gregory's Bank, Worcester.

HAMBUROIS (Black).—Prize, S. Shaw, Stainland.

COCHIN CHICKENS (Cinnamon and Buff).—First, C. Felton, Birmingham.

COCHIN CHICKENS (Grouse and Partridge).—First, Miss V. W. Musgrove, Ormskirk. Second, T. Stretch, Boole.

COCHIN CHICKENS (Grouse and Partridge).—First, Miss V. W. Musgrove, Ormskirk. Second, T. Stretch, Boole. Highly Commended, T. Stretch, Boole.

COCHINS (White).—Prize, G. Lamb, Compton, Wolverhampton. Highly Commended, H. Bates, Birmingham. Commended, G. C. Whitwell, Kendal.

SINGLE COCKS.

SPANISH (White-faced).—First, Miss M. L. Rake, Bristol. Second; E. Brown, Sheffield. Highly Commended, T. P. Wood, jun., Chesterfield; J. W. Smith, Oundle, Northamptonshire; R. Paton, Kilmarnock, Argyshire.

SPANISH (Red-faced).—Prize, Mrs. M. L. Rake, Bristol.

DORINGS (Cinnamon and Buff).—First, Lady J. Cornwallis, Staplehurst. Second, Lady L. Thynne, Worthing.

DORINGS (Silver Grey).—Prize, T. W. Hill, Heywood.

COCHIN-CHINA (Cinnamon and Buff).—First, Miss V. W. Musgrove, Ormskirk. Second, T. Stretch, Boole. Highly Commended, E. Smith, Manchester; C. Felton, Birmingham.

COCHIN-CHINAS (Grouse and Partridge).—First, P. Cartwright, Oswestry. Second, Miss V. W. Musgrove, Ormskirk. Highly Commended, H. Bates, Birmingham; P. Cartwright; T. Stretch, Boole.

COCHIN-CHINAS (White).—Prize, G. C. Whitwell, Kendal.

COCHIN-CHINAS (Black).—First, E. Hutton, Pulsey, Leeds. Second, T. W. Hill, Heywood. Highly Commended, E. Parkinson, Foulton-le-Fylde.

HAMBUROIS Silver-pencilled.—Prize, W. H. Kerr, Worcester.

HAMBUROIS (Golden-spangled).—Prize, H. W. B. Ferwick, Helmsley, Yorkshire.

HAMBUROIS Silver-spangled.—Prize, S. Shaw, Stainland.

POLANDS (black with White Crest).—Prize, C. J. Samuels, Manchester.

BANTAMS (Game).—First, J. Camb, Southwell, Notts. Second, J. Craig, Kendall. Third, T. H. D. Bayly, Biggleswade, Beds. Highly Commended,

M. Turner, Preston; R. H. Postans, Brentwood, Essex; W. Worrall, Liverpool; R. Hawkeley, jun., Nottingham.

SWEETSTAKES.

GAME COCKS.—First, J. Hindson, Everton. Second, J. Fletcher, Manchester. Third, G. W. Moss, the Beach, Algbath. Fourth, H. Worrall, West Derby. Fifth, J. Stubbs, Stafford. Highly Commended, E. Archer, Malvern; S. Matthew, Stowmarket, Suffolk; E. Lister, Cheshire; C. Chaloner, Workop; J. S. Butler, Poulton-le-Fylde; H. Worrall; N. Grimshaw, Burnley; W. Watson, Cornwall. Commended, J. Hindson; A. G. Brooke, St. Bees, Whitehaven.

GAME COCKS (Lace).—First, G. W. Moss, Algbath. Second, J. Stubbs, Stafford. Third, E. Archer, Malvern. Fourth, J. Fletcher, Manchester. Fifth, W. Cox, Derby. Highly Commended, J. Wood, Wigan; E. Archer; G. Cargey, Stone, Staffordshire; R. L. Robinson, Ulverston. Commended, J. Stubbs; G. Cargey; C. Chaloner, Workop; J. Firth, Halifax.

PIGEONS.

The show of pigeons, although not very numerous, comprised many first-class birds which have taken prizes at most of the principal shows in the kingdom, several of the leading fanciers being represented. *Carriers* formed the first class, but prizes being awarded to Duns of very great merit. Mr. Eden maintained his first position. Good Blacks were also shown by the same exhibitor, Mr. Rake, and Mr. Goss, of Plymouth.

In *Almond Tumblers*, Mr. Eden taking first with a pair, wonderful in head and beak, the Birmingham decision being reversed. Mr. Rake taking second with good feathered birds. In *Tumblers*, any other variety, Mr. Cannon secured first with *Black Mottles*; Mr. Eden's *Kites* being second.

The entry for *Pouters* was small, but contained first-class birds, Mr. Eden taking first with his well-known *Blues*. Master Smith's birds of the same colour being second.

Jacobins mustered strongly, Mr. Lawrence's *Yellows* deserving their first position, closely pressed, however, by Mr. Shaw's *Reds*.

The competition in *Turbits* was very close. Very fine small *Blues* of Mr. Shaw's winning. *Reds* being second. Good *Silvers* receiving high commendation.

Barbs were an extraordinary class, numbering fourteen pens, many worthy of a prize. Mr. Rake's *Blacks* stood first. The second being awarded to capital *Yellows* belonging to Mr. Lawrence.

Owls were a very pretty class, Mr. Rake's famed *Whites* as usual being to the fore. Mr. Morris's *Blues* second.

Fantails were an ordinary class. Plain-headed *Whites* and *Blacks* respectively obtaining both prizes.

In *Trumpeters*, Mr. Shaw's *Mottles* added one more to the list of honours they have obtained for their owner; well-feathered *Whites* being second; and good *Blacks* highly commended.

For any other breed the competition was keen, *Black Spots* again being first, *Swallows* second, *Blue Russians* third, and *Brunswicks* fourth.

The silver cup, value £5, given for *Carriers* and *Powers*, made another addition to the sidebar of Mr. Eden.

A second cup of the same value was offered for *Barbs* and *Jacobins*, which was carried off by Mr. Lawrence.

For *Owls* and *Turbits* a like silver cup was awarded to Mr. Henry Morris, for his well-known *White Owls* and a very pretty pair of *Red Turbits*, the hen especially being good.

The awards in the department gave great and general satisfaction.

CARRIERS.—First, P. Eden, Salford. Second, W. Hurton, Birmingham. Highly Commended, W. Hurton; P. Eden; McGregor Rake, Bristol; F. Goss, Plymouth.

ALMOND TUMBLERS.—First, P. Eden, Salford. Second, McGregor Rake, Bristol. Highly Commended, P. Eden; W. Cannon, Bradford (Black Mottles). Second, P. Eden, Salford (Kite). Highly Commended, F. E. Else, Bayswater, London (Black Mottles); S. Shaw, Stainland; G. Goore, Algbath Vale (Blue Beards).

POUTERS.—First, P. Eden, Salford (Blue). Second, Master H. Smith, Droydsda (Blue). Highly Commended, P. Eden (Blue); Master H. Smith (White).

JACOBIANS.—First, J. T. Lawrence, Newbie Terrace (Yellow). Second, S. Shaw, Stainland (Red). Highly Commended, F. E. Else, Bayswater (White); W. Cannon, Bradford (Black); H. Morris, Forest Hill, Kent (Yellow); J. T. Lawrence (Black).

TURBITS.—First, S. Shaw, Stainland (Blue). Second, J. T. Lawrence, Newbie Terrace (Red). Highly Commended, W. Cannon, Bradford (Silver); E. A. Hart, Ave, Birmingham (Silver); J. T. Lawrence (Yellow).

BARBS.—First, McGregor Rake, Bristol (Black). Second, J. T. Lawrence, Newbie Terrace (Yellow). Highly Commended, P. Eden, Salford (Black) and Yellow; S. Shaw, Stainland (Black); G. Goore, Algbath Vale (Black); J. T. Lawrence (C. Yellow).

OWLS.—First, McGregor Rake, Bristol (White). Second, H. Morris, Forest Hill, Kent (Blue). Highly Commended, D. Thwaites, Rock Ferry, Cheshire (White); W. Cannon, Bradford (Silver); F. Key, Beverly (White).

FANTAILS.—First, W. Cannon, Bradford (White). Second, G. Goore, Algbath Vale (Black). Highly Commended, J. R. Jessop, Hull; G. Goore; J. T. Lawrence, Newbie Terrace.

TRUMPETERS.—First, S. Shaw, Stainland (Mottled). Second, W. H. C. Oates, Newark, Notts (White). Highly Comended, Master H. Smith, Drogheada (Black).

ANY OTHER BREEDS.—First and Fourth, S. Shaw, Stainland (Black Spots and Bands). Second, Master H. Smith, Drogheada (Swallows). Third, G. Gore, Aigburth Vale (Blue Hussians). Highly Comended, Lady E. Talbot, Preston; W. Horton, Michells, Birmingham; J. Septon, Preston; F. E. Key, Beverley; G. Gore; H. Morris, Forest Hill, Kent; E. A. Hargrove, Birmingham.

CARRIERS AND PORTERS.—Silver Cup, F. Eden, Salford (Black Carriers and White Porters).

BARNS AND JACOBIANS.—Silver Cup, J. T. Lawrence, Newbie Terrace (Black Barbs or Yellow Jacobians). Highly Comended, J. T. Lawrence. **OWLS AND TURKIS**.—Silver Cup, H. Morris, Forest Hill, Kent (White Owls and Red Turbets). Highly Comended, W. Cannon, Bradford; F. E. Else, Bayswater, London; S. Shaw, Stainland; G. Gore, Aigburth Vale.

JUDGES.—Of *Poultry*, Charles Ballance, Esq., Taunton, Somerset; Richard Tebbay, Esq., Preston; George Fell, Esq., Warrington. Of *Pigeons*, Mr. T. J. Charlton, of Stanley, near Wakefield.

TRIMMING FOWLS FOR EXHIBITION.

I AM glad to see that the subject of trimming Spanish fowls is again brought before the poultry world. In your "Letter Box," in reply to "IGNORAMUS," you say, "Plucking out the feathers over the eye of a Spanish fowl would not only disqualify the pen, but subject you to the disgrace of having the fact written on a card and stuck up against the pen." This is what every honest exhibitor of Spanish fowls desires to see done. I would like to ask our poultry judges how it is they do not carry into execution this salutary plan, and stamp the exhibitors of such birds with the infamy they so richly deserve. This appears to me to be the only effectual mode of putting a stop to such disgraceful acts. Surely our keen-eyed judges cannot pass a pen of birds, one or more of which has been "plucked," without discovering the "attempt to cheat."

I feel quite sure if our judges were determined to put a stop to this galling and disreputable conduct they might do so. Let them carry into practice the penalty, and disqualify the guilty party from ever exhibiting again. This done once, I think we should hear no more complaints of Spanish fowls being trimmed.

—X. Y. Z.

NANTWICH POULTRY EXHIBITION.

THIS Association has now been established for three years; the regulations made at the onset were of a peculiar character, and have been throughout rigidly enforced. One of the rules limits the entries to parties resident within thirteen miles of the Nantwich Town Hall, and another, equally binding, enjoins that no poultry shall be exhibited except by their real owner. Most poultry amateurs would naturally suppose, that from these combined causes the Show would be limited both as to the number of entries, and yet more so as to the quality of the fowls competing. The Show just closed, however, proves beyond question that the locality can produce specimens of equal excellence to those met with at our largest meetings; and again, that in almost all classes the competition was a good one. The Nantwich Town Hall is peculiarly well adapted for the purposes of a poultry show—being well-lighted from both sides, and affording excellent ventilation. The pens are of similar construction to those of Turner, of Shuffield, and the Committee are worthy of all praise for the attention paid to the poultry whilst under their care; the fact is, more perfect arrangements are rarely met with. The only improvement that suggested itself to our minds, was that the centre pens should have been placed lengthways instead of across the Hall, as, by gaining an improved light, it would have rendered a general inspection far more easy.

In our remarks we intend to take the classes as they occur in the prize list. *Spanish* fowls head that list; the adults though good birds, were not shown in the condition we could have wished to find them so late in the season, many of them as yet having not recovered from moulting. Even the winners of the silver cup were imperfect on this point. The *Chickens* were in much better trim. A very good pen in this class was disqualified, from the fact of containing a cock that certainly must have seen several winters: this glaring deception, however, met its due reward.

The arrangements of the Committee placed *Aylesbury Ducks* next in order. Very many of the pens were really praiseworthy, and large-framed birds were general; yet when brought to scale, they proved much lighter than customary, so much so

that 17 lbs. were the full weight of even the first-prize pen! The *Rouen Ducks* were, throughout, a good medium class. In the "Extra Duck Class" a pen of East Indians took the first prize, a pen of well-matched *Muscovys* second, and the common *Wild Duck* stood third.

In *Geese*, the *Emden* variety far excelled the *Toulouse*. When tested by the scales they weighed 63½ lbs., their nearest opponents, a pen of *Grey White-faced Geese*, being 66½ lbs., whilst all three of the remaining pens of *Toulouse* reached 65 lbs. each pen. Judged merely by the eye, there are few parties who would not have formed very different conclusions. The first-prize pen of *Cambridge Turkeys* was the only lot that needs especial mention.

The *Dorkings*, whether *White* or *Grey*, were capital, the truth being, that amateurs may attend the majority of our public meetings without seeing better.

In *Cochins*, the *Partridge-coloured* and also the *White* ones were most creditable specimens; but the *Buffs* proved as decidedly indifferent. A wretchedly poor specimen of a *Buff Cochin* cock was the only entry for a sweepstakes. It must certainly have been a compassionate act on the part of the arbitrator to award him a prize, of his own entrance money back again (after the deduction of 1s. to the funds of the Society in accordance to the rules), for he certainly ill-deserved it. The fact is soon told—all the sweepstakes, except for *Game* cocks, at Nantwich proved a failure.

In the *Hamburgh* classes were many excellent pens, but not a few, otherwise perfect, lost all hope of success from the pen containing one bird with a loose comb lopping aside. We have again and again drawn attention to this always fatal objection.

The *Silver-spangled Polands* and the *Blacks* with *White Crests* were perfect, the former variety taking the principal silver cup for the best pen of poultry exhibited. This remark holds equally good in respect to the *Chicken Poland* class; but here, again, an old cock was detected shown as a chicken, disqualification, of course, ensued.

Among the amateurs present the remark was universal that the *Game* classes were as good as could be wished for. The neighbourhood of Nantwich is proverbial for its *Game* fowls, and we confess we never remember to have seen so spirited and close a competition—so much so, indeed, that scarcely a single bird was passed by the Judge without handling, and this infallible test proved them almost without an exception to be in first-rate condition. As a whole, the *Brown Reds* were, perhaps, the most perfect. But we cannot pass over without especial mention the *Black-breasted Red cocker* belonging to Mrs. Broughton, of Wistaston Hall: of his age we never yet saw a better. This youngster added the inn-keepers' silver cup to the side-board of his mistress.

The *Black Game Cocks* shown were decidedly the best of the colour we ever met with, and were birds of great power. This strain of *Game* fowls is much approved in the Nantwich district; those shown were peculiarly hard-feathered birds, possessed great constitution, and are reported to be indomitable in the cock-pit. We were gratified to see so much improvement in the dubbing of the *Game* cocks when compared to those shown at the previous meetings of this Society, and by referring to the published lists of prizetakers throughout the kingdom we find no small proportion of premiums are now being secured by breeders of *Game* fowls in this district.

The muster of *Bantams* was weak, but the collection of *Singing Birds* and *Pigeons*, also confined to local competition, was very praiseworthy.

The weather being most favourable the attendance was unusually good, most of the resident nobility and gentry of the district being present.

The following were the awards:—

SPANISH.—Silver Plate, E. Viggor, Over. Second, J. Grocott, Nantwich, Third, J. Sheen, Tilston. Highly Comended, W. Woolley, Bunbury, Comended, J. Heath, Nantwich. *Chickens*.—First, J. Grocott. Second, W. Woolley.

DUCKS (Aylesbury).—First, E. Viggor, Over. Second, J. Wright, Inn, Minshall, Third, T. Egly, Winsford. Highly Comended, J. B. Erce, Keele, Staffs.

DUCKS (Any other variety).—First, T. Burgess, Burleydam. Second, E. Viggor, Over.

GEESE (Any other variety).—First, W. Furnival, Norton. Second, J. Windsor, Chorley Stuck, Third, J. Sheen, Tilston. Highly Comended, E. Viggor, Over. Comended, S. P. Hope, Ryley Hall.

TURKEYS (Any colour).—First, H. Astrod, Dodington Hall. Second and Third, W. H. Hornby, M.P., Sirensbridge Hall.

DOEKINGS (White).—First, Mrs. Tollenache, Dorfield Hall. Second, T. Wood, Minshall Vernon. Third, E. B. Davies, Eadswick Hall. Highly Commended, Mrs. Tollenache.

DOEKINGS (Any other colour).—First, Mrs. Broughton, Wistaton Hall. Second, T. Burgess, Barleydam. Third, E. Tudman, Ash Grove. Highly Commended, H. Akford, Dodington; E. Tudman, Commended, T. Green, Stapley. **CHICKENS.**—First, Mrs. Broughton. Second, Mrs. E. Tudman, Ash Grove. Third, Mrs. Tollenache, Dorfield Hall. Highly Commended, Mrs. E. Tudman; T. Burgess.

COCHINS-CHINA (Cinnamon n. Buff, and Partridge).—First and Second, E. Tudman, Ash Grove. **CHICKENS.**—First and Second, E. Tudman.

COCHINS-CHINA (Any other colour).—First, J. Dodd, Minshall Vernon. Second, J. Dutton, Bunbury. Highly Commended, J. Dodd. **CHICKENS.**—First, J. Dodd. Second, G. Williams n. Nantwich.

COCHINS-CHINA (single). Cocks, Sweepstakes.—Prize, W. H. Horby, M.P., Shrewbridge.

HAMBERG S (G Men-pencilled).—First, D. Harding, Middlewich. Second, G. Williams n. Nantwich. Third, J. Kitchen, Over Lane. Commended, W. H. Horby, M.P., Shrewbridge Hall.

HAMBERG S (Silver-pencilled).—First and Second, D. Harding, Middlewich. Third, G. Williams n. Nantwich.

HAMBERG S (Golden-spangled).—First and Third, T. Burgess, Barleydam. (Second withheld.)

HAMBERG S (Ferry-spangled).—First, J. B. Bruce, Keele, Staffordshire. Second, T. Rigby, Fenny Wood. Third, T. Dale, Middlewich. Commended, T. Dale.

SINGLE HAMBERG COCKS (Spangled).—Prize, T. Dale, Middlewich.

SINGLE HAMBERG COCKS (Pencilled).—Prize, W. B. Letches, Whitechurch. **POLANDS (Any variety).**—Cup and Third, J. Heath, Nantwich. (Silver-spangled Poland.) Second, F. Sprouston, Middlewich. **CHICKENS.**—First, F. Sprouston. Second, J. Heath. Third, G. Williams n. Nantwich.

GAME (Black-breasted Reds).—First, E. Vigor, Over. Second, J. Pedley, Nantwich. Third, T. Burgess, Barleydam. Highly Commended, J. Heath, Nantwich. Fourth, J. Grocott, Nantwich. **CHICKENS.**—First, J. Heath. Second, T. Moore, Nantwich. Third, W. Forster, Marsh Lane. Highly Commended, E. Owen, Copenhall; T. Burgess; J. Grocott; J. Heath.

GAME (Brown-breasted Reds).—First, E. Bower, Nantwich. Second, J. Heath, Nantwich. Third, T. Burgess, Barleydam. Highly Commended, E. Bower, Nantwich; T. Burgess; J. Pedley, Nantwich; J. Grocott, Nantwich. **CHICKENS.**—First and Second, T. Burgess. Third, A. Phillips, Winsford. Highly Commended, E. Tudman, Whitchurch; J. Pedley; J. Grocott; C. Hollinhead, Minshall Vernon; W. Sowerbutts, Nantwich; J. Heath, Commended, J. Heath.

GAME (Any other colour).—First, T. Burgess, Barleydam. Second, R. Roberts, Coole Lane. Third, W. Forster, Marsh Lane. **CHICKENS.**—First, T. Burgess. Second, J. G. Pearson, Whitechurch. Third, T. Crawley, jun., Tarpory. Commended, T. Burgess.

GAME (Any variety).—First, J. Heath, Nantwich. Second, T. Burgess, Barleydam. Third, W. Arncliffe, Norton. Highly Commended, W. Forster, Marsh Lane. Commended, E. Bower, Nantwich.

SINGLE COCKS.

GAME (Black-breasted Reds).—First, J. Grocott, Nantwich. Second, J. Heath, Nantwich. Third, W. Galley, Nantwich.

GAME (Brown-breasted Reds).—First, T. Burgess, Barleydam. Second, W. Forster, Marsh Lane. Third, C. Brown, Minshall Vernon. Highly Commended, J. Wilkinson, Norbury; J. Heath, Nantwich. Commended, T. Burgess; S. Blackburn, Nantwich.

GAME OR ANY OTHER COLOUR.—First, W. Forster, Marsh Lane. Second, A. Heath, Winsford. Third, J. Wilkinson, Norbury. Highly Commended, T. Burgess, Barleydam; E. Bower, Nantwich. Commended, T. Crawley, Tarpory.

BEST GAME COCKEREEL (any colour).—Silver Cup, Mrs. Broughton, Wistaton Hall. Second, T. Burgess, Barleydam. Third, J. Peoley, Nantwich. Fourth, T. Simpson, Nantwich. Highly Commended, W. Cawley, Spangrow; J. Hainson, Nantwich; T. Whittingham, Eatheron; W. Farmer, Nantwich; J. Willet, Nantwich; W. Furnival, Norton; E. Bower, Nantwich. Commended, S. Blackburn, Nantwich.

SWEETSTAKES.

GAME COCK (any age or colour).—First, T. Burgess, Barleydam. Second, W. Farmer, Nantwich. Third, J. Parton, Nantwich. Highly Commended, J. Heath, Nantwich.

BANTAMS (Game, any colour).—First and Third, T. Burgess, Barleydam. Second, J. Grocott, Nantwich. Highly Commended, W. Griffith, Nantwich; F. Peoley, Nantwich.

BANTAMS (Any other variety).—First, T. Rigby, Fenny Wood. Second, S. Boffey, Wilston.

SINGLE GAME BANTAM COCK.—Prize, T. Burgess, Barleydam.

Mr. Edward Hewitt, of Sparkbrook, near Birmingham, officiated as Judge, and expressed himself in high terms of the arrangements generally.

LIGURIAN BEES AS HONEY-GATHERERS.

As "AN OLD FRIEND OF THE BLACK BEE" does not appear convinced by the evidence of "A DEVONSHIRE BEE-KEEPER," as to the superiority of the Ligurians on the "main point" of honey-gathering, I think it would be very desirable to call another witness into court, and would therefore beg Mr. Fox, who from keeping black bees in the same neighbourhood, must have had ample opportunities of judging, to favour us with the results of his experience and observations. If as favourable on this point as others, it is my intention to add a stock of Ligurians to my apiary.—AN INQUIRER.

[In reply to "AN INQUIRER," I can only say that with respect to what he considers the "main point"—viz., the honey-gathering qualities of the Ligurians, I can say yet no

results of my own personal experience. The queens sent to me from Switzerland proved failures, as also some attempts to introduce among black bees queens supplied me by "A DEVONSHIRE BEE-KEEPER," and it was not until the 18th of July last, that I had the pleasure of possessing an undoubtedly pure Ligurian queen at the head of a stock. Our honey season was over, and I was also much more desirous of multiplying queens of her progeny than of obtaining honey.

Previous to the successful introduction of the Ligurian queen, I had, through the kindness of my friend aforesaid, obtained royal cells, from which I had two Ligurian mothers, whose progeny were hybrids, though in appearance quite equal to those bred by any of the best yellow queens. One of these was at the head of an artificial swarm, and which I fear has, in some mysterious manner, been lost. The other was given to a hive from which all the bees had been expelled to form a large artificial swarm; a few bees being obtained from another stock to hatch out the brood. No attempt was made to induce them to work honey in a super, but the bees became very numerous in autumn, and the hive very heavy. Their activity, beyond that of any other hive in the same garden, was very remarkable.

But, although I cannot speak from my own experience, I can confirm every word that "A DEVONSHIRE BEE-KEEPER" has written in their favour. Of all the achievements in bee-keeping I have ever seen or heard of, nothing can compare to that accomplished by him with one of his hives; the account of which he has himself given in this Journal. From this single colony comb after comb, teeming with brood in all stages, was removed, together with bees, until (I speak from memory) nine artificial swarms were created. Notwithstanding this enormous drain on the population, the hive became so crowded that a large super was put on, and in a very short space of time nearly 40 lbs. of super-honey were collected.

As I saw this hive several times a week, and watched the progress of the experiments with regard to the multiplication of swarms, as well as that of the filling of the super, I can speak as positively in favour of the Ligurian bees as if it had occurred in my own apiary, and would strongly advise "AN INQUIRER" to lose no time in obtaining a stock of them.—S. B. FOX.]

HOW I BECAME AN OXFORDSHIRE BEE-KEEPER.

(Continued from page 327.)

I CONFESS to a glass of good hearty beer at meal time, our forefathers did the same; but meat! that was, when our forefathers were pagans, considered a beverage only sufficiently good for the halls of Vallula, their heaven, to be drunk there after they were dead in reward for bravery, out of the skulls of their enemies whom they had slaughtered during life! In ancient times too, honey was considered of the greatest importance, and a bee-master no insignificant person. Even places took their names from its production, as Honiton in Devonshire, of which Westcote wrote, "This town claims priority for antiquity before many other; but for the name, y! I should say it was taken from the abundance of honey there made or found. I persuaded myself you would smile, and yet that may not be altogether sans reason, in regard to the hills adjoining, on which abundance of thyme [or tyme] grows, in which the pretty creatures [the bees] are much delighted, and feed willingly thereon." But I must cease from anecdote and come to present reality.

So the honey having run from the combs, though not nearly so effectually as I could have wished, notwithstanding the moderate additional warmth of the fire, a method of facilitating the process I recommend with great reservation, as I never resort to the practice unless the honey is very thick and sluggish. Virgin honey would seldom, if ever, require the extra incitement; at any rate, whatever residue of honey does remain I reclaim it by emptying the contents of the canvass bag into a pan with water, in proportions of one quart of water to two quarts of comb, first making the water mix with what honey adheres to the bees by rising and wringing them into it. Occasionally stir the mass well with a wooden spoon, and at the expiration of three days strain the liquid through a bag, or bags, into a clean pan, and add and dissolve 2 lbs. of loaf sugar per gallon. Then place it approaching the fire, or in a temperature ranging 65°; spread a spoonful of yeast on a slice of toasted bread, and deposit it upon the surface of the liquor,

where fermentation will soon commence, and may be continued uninterrupted during three or four days, when it must be poured into a barrel, or stone bottle, and placed in an atmosphere a few degrees cooler to finish working, during which process it must be filled up occasionally from a jug containing a reserve of the liquor. A fortnight or three weeks are generally the time it takes to accomplish this. Then place the barrel or jar in the cellar, or in a cool place till the hissing becomes faint, when it is fit to cork down; afterwards, in a month or so, rack it off and rinse out the residuum, immediately return the liquor, and when it is become fine bottle it off, sooner or later to suit convenience; though, if the quantity is large, two years duration in the barrel would considerably add to its quality. I do not mean to pretend that it would even then equal the famed mead of our Saxon forefathers; but it will prove, rather than to have allowed the honey to become wasted, an economical, and by many considered a very palatable beverage. The specimen I submit is five years old, and I made it exactly after the above prescription. I also send you a specimen of my mead vinegar made in the same manner, with the exception I added coarse brown sugar in lieu of the loaf, and I made use of badly fitting old corks, and placed the bottles in a garret in all the sun they could get during two summers. It is six years old; methinks it a very good salad vinegar, and one of which we know the composition.

This year, in consequence of a greater quantity of honey remaining to the run-off comb, I have not allowed any sugar to the mead; it has gone through all its process well up to the present, and it is rapidly finishing. I think it will prove sweet enough, and if it should not I can convert it into vinegar.

Turn me now to when we administered the yeasted toast, and then turn the smashed comb out of the bags once more into the pan, to remain till wanted; for I must come to consider the supers, with the remnant brood-combs, which have been upon age 2 and age 1 a fortnight. A journey from home induced me to take them off again so soon, in order that I might leave the hives in their winter wind-proof trim during my absence. I found the brood scarcely all hatched out, and the bees which were performing their foster-maternal duties were very reluctant to leave. It was dusk before they managed to tear themselves from the poor little forlorn-looking grubs in their unsealed cells; they would in three or four days have all reached maturity. I shall in future allow three weeks, at least, for this kind of super-work. From practice I can tolerably well judge the weight of a hive by lifting it, board and all, and on the 16th of September mine weighed in honey from 35 lbs. to 40 lbs. on the average, excepting age 1, which I set down at 20 lbs. I resolved on my return to extra-provision it with the inferior run honey, discoloured and disqualified by the bee-bread, which I did, and found since its increase by joints that fresh vigour indeed had at once been imparted to the colony, as they had added several pounds of honey to its stores. I gave them 8 lbs. of the discoloured honey in my fig-drum-feeder at 5 o'clock A.M. on the 2nd of October, and by 9 next morning they had stored it away, and the hive weighed nearly 35 lbs.

I explained my method of applying the feeder in No. 639, old series, though in my original notes I had intended the paper to appear here. So now we will melt the combs, which must be put into a canvass bag, the filled bag slipped within another, and to have their mouths tied with a piece of string. Then put them into a large iron pot, or saucepan, three parts filled with cold water and place it upon the fire to become heated, when the wax will rise like fat to the surface. It must be skimmed off with a ladle into a basin of clean cold water, and so on till no more can be gained from the bags in the boiler. The latter should then be emptied of their debris, which chiefly consists of the parchment-like linings of the cells. My six-year-old wax consisted of an astonishing number of these linings for each cell, and they are easily untwined the one from the other in their wet state from the boiling. No wonder the bees become small and dwindle off in very old stocks! Put the skimmed wax from the basin into a steppan, or pippin, to merely melt, not boil it, so that it can be poured into a soup-plate or earthenware shape of some sort. When the wax is nearly cold turn it out of the shape and flay away the bottom part with a knife should it appear grouty or discoloured from settlings. In fact, it would improve the appearance of the wax altogether to melt it over once or twice more even; and that is how the enclosed specimen was operated upon.

The furniture-cream is made from my virgin or super wax, and

the waterproof dubbing for shooting-boots is made from my old hive wax. Both of the concoctions are excellent in their way, but their receipts are a sealed letter for me. They are manufactured by my brother, who has an advertisement in the pages of this Journal. But after all these specimens, writings, and advice, the great feature is the honey, and you cannot form a just opinion without I enclose a medium of that also. Now, I think, I have exhausted the pith from my notes and said all that is necessary for me to say on my management, and the domestic economy accruing from the honey bee.—URWAIDS AND OSWALDS.

THE CHEMISTRY OF HONEY.

In an article under the above head which appears in your last Number, I perceive that it is decided by a quotation from Mr. Taylor's excellent work, that M. Reaumur, the great French naturalist, and probably also the very highest authority upon such a point, is altogether wrong in stating that a great change takes place in simple syrup during its sojourn in the stomach of the bee. As I happen to hold, and have already expressed a similar opinion to M. Reaumur, I would suggest that Mr. Taylor and the Editors of THE JOURNAL OF HORTICULTURE should resolve themselves into a committee of taste to whom I will forward a portion of comb in which simple syrup has been stored by bees, to be fairly tested by them at their breakfast tables, if they will, on their parts, undertake to submit an impartial statement of the result to the readers of THE JOURNAL OF HORTICULTURE.—A DEVONSHIRE BEE-KEEPER.

P.S.—If it be a fact, as stated, that sugar cannot crystallise if a little acid is contained in the syrup, permit me to ask how it is that sugar is so apt to crystallise in household preserves in which acid is always present?

[We must decline being the umpire, and should be unwilling to be satisfied with any experiments that were not conducted so as to exclude the possibility of error. To take syrup from the cells of an old stock would not satisfy us, for the reek of honey remains in them after the cells have been emptied of it by the bees.]

Sugar may crystallise in the gummy juice of fruits, though it will not in acidulated water. It is the result of the universal experience of the sugar-manufacturers in the East and West Indies, that the sugar will not crystallise until the acid in the boiling sugar-cane juice has been neutralised by adding to it lime.—EDS.]

PRESERVING KIDNEY BEANS.

WHEN Kidney Beans are in full bearing the supply is generally not only enough, but more. If those which are not wanted for immediate use are gathered when quite dry and laid in layers in a stone jar with a good sprinkling of salt between each layer, they will keep good for many months. I have been, and am now, using Kidney Beans which are as good as when they were plucked.—MARY.

OUR LETTER BOX.

CLAIMING FOWLS at SHOWS (A Reader).—So soon as the hour fixed for closing a show has arrived any right to claim birds at that show is done away; and any one attempting to enforce such a claim must be very ill-advised.

EGG-AND-CHICKEN-PRODUCING STOCK (*Hypnum*).—Our own experience is decidedly in favour of a coloured Dorking cock with Cochin-China pullets. They lay all the winter, and the chickens are large with abundance of meat and fat. The pullets are apt to brood in the spring and summer, and, therefore, we would have some Spanish hens to supply eggs during those seasons. Thanks for the *Hypnum*.

PARTRIDGE AND GROUSE COCHIN-CHINA (*Inquirer*).—The following are the distinctive descriptions, extracted from our "Poultry Book for the Many":—"Partridge.—Pinnings: cock a black-breasted red bird. Hen pencilled with black on a buff ground throughout, the darker markings pre-following the outline of the feather. Grouse.—The hens darker than the foregoing, less of the ground colour being visible; the markings also are less distinct, closer, and rather to be described as a grizzle. Cock, a dark, mottled-breasted red bird." They are very distinct, and if you allow a cork of one of the varieties to run with a hen of both sorts, the chickens from the hens not of the same variety as the cock will have usually a mixed plumage, which would endanger their success as exhibition birds.

VARIETIES OF THE CANARY (*A Young Enthusiast*).—You will find all the varieties of CANARIES fully described in THE COTTAGE GARDENER during 1860, Vol. XXIV, and XXV. The series is now nearly completed and will be published in a small volume.—B. P. B.

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last thirty-five years, the average highest and lowest temperatures of these days are 43.7° and 31.4° respectively. The greatest heat, 58°, occurred on the 23rd in 1849; and the lowest cold, 2°, on the 17th in 1855. During the period 136 days were fine, and on 102 rain fell.

ROOTS AND LEAVES, AND THEIR ACTION.

COUNTRY gentleman and his gardener had an argument about roots and leaves and their action, and referred to the writer's opinion, by which they agreed to abide. But the subject is far too good to be disposed of privately, too much having been said on the subject.

The gardener writes thus: "I have a question in vegetable physiology to ask, which is so simple and yet so enigmatical, that I do not want to

bore the Editors of THE JOURNAL OF HORTICULTURE with it, and I thought I might trespass on you this once." Just think if one hundred readers only out of so many thousands having "thought" the same thing, and you will see the necessity of the constant announcement of "We request that no one will write privately," &c., issued weekly "to correspondents," and yet human nature is so weak in the strongest of us, that every one of us writers in this Journal feels pleased when he is asked, or trusted individually about what has been written, although it is out of all reason to suppose for one moment that any of us could stand the artillery of private correspondence. I briefly answered the "good master" and his excellent gardener, but told them at the same time I should make their argument a text for a discussion in these pages without mentioning names.

The argument was "about the rooting of Vines. The master maintained that spongioles are thrown out simultaneously with the buds. Whilst the gardener holds that the heat of the house liquifies the sap in the stems of the Vines, the buds burst, and root action does not commence till after the buds are developed."

Now, just read over their argument, or rather their difference again, and make yourself master of it, if you take any interest in the subject; for depend upon it we shall have currents of hot air passing over it ere the end of it is yet seen in the distance.

I wrote back to say, that as far as I could see they were both practically rot for the mark, but that they did not explain themselves according to theory—that, in fact, they were in the same kind of fix as those who discussed the disease in variegated plants. With the gardener I took upon myself to be more plain, and I told him his notion of the heat liquifying the sap in the stem was exactly the reverse of the fact. But the question reads two ways, and he was perfectly right, while I maintain that he was as far wrong as that doctor was whose views on the same subject Dr. Lindley said, not long ago, were "exaggerated nonsense." But gardeners must not come to such hard blows in discussing questions referring to their craft; it would not look well in them to

do so, and big people never think well of people under them, if they, or rather we, cannot master our tempers, and keep ourselves as much as their ice from currents of hot air.

"Leaves make roots and roots make leaves," is a common and a true saying, but it is not all the truth. Roots are made without leaves, and leaves are made without roots; but neither will go on prosperously for more than one season in the absence of the other, save in the kinds of plants to which leaves were not ordained at the beginning. But the leaves are not the first cause of setting roots in motion, or, as the gentleman puts it, "of throwing out spongioles."

But let us explain as we go. Spongioles or spongelets, or sponge-like organs, are the very ends of the roots of all plants; and a worsted glove on the human hand would make any of the fingers represent the end of a root more nearly than anything to which it had ever been likened. The end of each finger would be the actual end of the wood of the root, and the worsted finger of the glove would be the spongelet, as you would know to your cost, if you put the finger of the glove in contact with scalding water. The worsted threads and fibres would suck in the boiling water like a sponge, or spongelet, or spongelet, and you would burn your fingers, as many do who do not understand the glove-in-hand in an argument. Then the sponge-like power at the ends of the roots is a hydro-metrical action, not the action of the leaves far off or near to it.

All parts of the system and circulations of plants have been likened to similar parts in the animal kingdom, except the one part which is the nearest to the truth, and that of itself is sufficiently singular. With the exception of the sexes in both kingdoms, there is nothing in all the vegetable kingdom which comes the nearest to the pulse in animals than the action of a spongelet. I am not doctor enough to know exactly the precise period at which the pulse begins in the babe, but we all know that the pulse does not cease in the adult until it is all over in this world; and it is exactly so in the vegetable kingdom. The root action, that of the spongelet, never ceases day or night, winter or summer, from the moment the embryo of the seed is free from the lobes in germination, till the ancient Oak or Vine has crumbled by natural decay from the effects of old age. I say "crumbled," because in all trees the roots survive the trunk under ordinary circumstances. Then, if root action really begins at that early age, and never ceases, like the pulse in animals, till death occurs, whence is it? It has the same source as the beating of your own heart—it is consequent on vitality, and on it alone. It is the power of life in us, and that of existence in plants and trees. Let root action once cease entirely, except from some temporary cause, as by extreme frost, and the life of the strongest tree is gone with it. How, then, comes it that we gardeners speak and write so confidently of the roots being thrown out only at such and such times, of the root action having commenced, or must only begin, or in reference to, a certain progress of the annual growth?

Before answering these two questions, allow me first to discourse on my text and keep these answers back for the application I mean to give to the subject. However, if you have seen the drift of the tale, you see that there cannot be any such thing as the beginning of root action in the forming of fruit trees planted out in borders. Then the text is, that the heat in a vinery at forcing early in the spring "liquifies the sap in the stems of the Vines, the buds burst, and root action does not commence till after the buds are developed." And a very good thing it would be to some of us if it began even then in the sense of the meaning here implied. But I said the way the gardener put it would read two ways, and I take the way which is against himself first.

The heat of a vinery does not liquify the sap in the stems—it does exactly the contrary; the sap is thinnest the moment it is within the spongelet at the extreme tip of the root, and it is then in motion onwards by the force of vitality alone, without the assistance of the leaves, for then there are no leaves to give it force. The same is the then condition of the sap of all deciduous trees like the Vine. The force of vitality, or of life, aided by the returning heat of the spring, moves on the sap in all parts of the roots, stems, and branches of a tree. At first it is mere water in which are dissolved the salts and the essence of the kind of soil whence it is drawn together, with various gases. This water, called sap, so impregnated, in moving on mixes with the juices in the roots, and "liquifies," or melts, the vegetable mucilage in these juices; the mixture then becomes more dense than the sap was in the first instance; and in its progress upwards through the stems and branches, this denser fluid, or sap, acquires the same properties as the natural products of that kind of plant. If it be a tannin property, as in the Oak, the sap has it by this time without the aid of new leaves; if it is a Birch tree, the rising sap may be tapped and be made into Birch wine; if, as in the Sugar Maple, the same process of tapping will get sap to make sugar from, and so on, for all the properties, including poisons which are the products of trees, and all before the leaf is expanded; but recollect, these products are from the workings of the leaves of the preceding season or seasons.

At last the roots and the stems and branches are so full of this denser sap, which sap is so impregnated with these products, that if you prick some of them with a pin they would bleed, and ultimately they do actually burst—burst into new foliage. The large field for the expanse of the sap offered by the leaves, together with the vital power of the leaves themselves to draw in the sap, is the exact point at which the action of leaves begins to bear on the action of the spongelets, and gives to the vital action of the roots a tenfold force, more or less according to the kind of tree and the state of the roots as to their health and numbers.

The leaves are as much the stomach of plants as they are their lungs. The sap or food is now in the stomach for digestion, and it is just as essential to keep the stomach and the lungs of plants in good order as it is with ourselves. One of the conditions, the most essential for plants, is clear sunlight, for they cannot digest in the dark. The way they digest the most part of the sap is by parting with the more watery part of it by insensible perspiration from their upper surface, and thus rendering it more dense than formerly. Then, if the pores of leaves are filled up with dust or dirt it hinders digestion most certainly. So you see that clear light and a clean skin to the leaves are the two first elements for the healthy digestion in the leaves of the very food of plants.

After digestion—that is, after the food of plants, the rising sap, has been digested and mixed as one may say in the upper surface of leaves, it is called the true sap, and by this time it is made free of all waste and water, and has received the properties peculiar to the kind of plant, solely and altogether in the upper surface of the leaves. All that way of digestion and airing of the food of plants being now complete, the true sap falls into another set of channels on the under surface of leaves, by which it returns to the branches, stems, and lastly to the main limbs of the roots, there to remain to the spring rising again, after having expended in every part of the system that which was needful for its own increase, or for the maturity of its product.

Then, in the autumn, what with playing so many parts, and what with the returning cold of that season, the rest of the returning sap gets much thicker than it was on getting down from the leaves, and this condition of the sap they call by the curious name "inspissated," which is from two Latin words which

mean to thicken a fluid. Was that not a clear and definite expression of my friend, the gardener down the country, when he said the heat of that vinery liquified the inspissated or thickened sap of the preceding autumn, by adding to the natural force of vitality which impelled or forced up the much thinner rising sap as we have just seen? So you see the heat did the thing after all. But so many people think they are so wise as that they could see his meaning to be that the thick sap, the vegetable mucilage, as one might say by this time, had itself been liquified; whereas his meaning was that the heat accelerated the rising of thin sap, and this thin sap it was what he understood to liquify so much of the mucilage by coming in contact with it in the soft wood of the root and stems through which it ascends at this early period by forcing, and also at a later period by the natural force or stimulus of finer weather.

For my part I cannot see a pin's difference between the master and his gardener when I come to analyse the points on which they argued.

The definition of the mixture of the spring sap with the remains of the last autumn's reserved portion of the true sap of last year is a new one, and a very good one too, as it is just the opposite of inspissated. "Liquified" is as true an expression of the condition of the first movements of the sap in spring as "inspissated" is that of the condition of last season's remaining sap at the fall.

A *resumé* of the whole argument would stand somewhat in this fashion: Spongelets are the tip ends of all roots; they are present, under ordinary circumstances, from the sprouting of the seed till the plant dies of old age. Although the vital or life action of spongelets be slow in winter it never ceases except by frost or accident.

The cause of the action of spongelets is entirely independent on leaves or top growth—the cause is consequent on vitality alone; but, during the active period of growth, the requirements of the leaves, or of the system of the plant through its leaves, add powerfully to the vital action; and ground heat is the next greatest promoter of it. But, as by artificial means, gardeners can bring these auxiliaries to vital forces to bear upon their subject in hand before the natural period, so also by the same means can they prolong the vital force, and go on increasing the length of roots and the multiplication of spongelets for a long period after the leaves have fallen in the autumn.

I have seen the increase of the roots effected by express experiment; the root run out fox-tail fashion, or full of small fibres, to the length of 20 inches between the fall of the leaves and the bursting of the next crop of leaves. The fact is familiar to most gardeners in some way or other, and one gardener made the experiment with a bonfire-like movement, by which he made the sticks in garden rubbish, which he was charring, to strike roots in the dead of winter, and the ground was so warmed under, and near to the place, that no one ever knew how long the roots of trees in that direction had extended by the mere force of artificial heat without any assistance from the great promoter of the vital forces—the leaves. Some, again, cause the spongelets and all the fibrous roots to perish annually by drying the balls in which they were, and by a system of bottom heat they made ten new roots for every one they lost, with fresh mouths or sponge-like suckers, before a leaf is on to help them. But that side of the question another day.

D. BEATON.

A FEW DAYS IN IRELAND.—No. 14.

TRINITY COLLEGE GARDENS, DUBLIN.

(Continued from page 390.)

PERHAPS the most interesting thing to the lovers of the native Ferns would be some fine boxes of Killarney Fern (*Trichomanes radicans*), the boxes being placed inside of a greenhouse. These boxes are similar to the strong-glazed cases in which plants were sent home from China, and sent out to Australia. As far as we recollect, they would be 4½ feet long, 27 inches wide, and 24 inches high at the sides, with hipped ends a foot higher, and the top formed thus—of two hipped sides glazed, one side fixed, the other hinged at the ridge. In these boxes the Ferns are planted almost entirely in moss. There are small openings in the front of the box for air, and larger openings behind; the plants thus have plenty of air at all times, and have also plenty of light in winter and spring, especially in dull weather. In sum-

mer the tops are covered with a thin cloth, or paper, or a coating of whitening; in summer generally the plants are watered twice a-week, and once a-week in winter. We suspect, however, that in the former case they get many a dewing from a fine syringe. These plants had the finest fronds we had ever seen, many of them 18 inches in height, full of fruit, and spores vegetating freely. Moisture and free air seemed to be the chief things relied on. We believe some 9 inches or 10 inches are a good size to get these Fern-fronds in their natural habitats. We observed that the lid of each box was fastened with a small padlock, so we presume the Curator attends to these pets chiefly himself. Even the lock, however, could not keep pilferers from them. The slits for air in the box are narrow, but ladies had found them out and got their pretty hands through them too, and nipped off pieces as souvenirs. Would that some Venus among them would contrive a sort of trap, not to hurt, but to hold the fair culprits until they should feel thoroughly ashamed of themselves. The Andreewii variety we also noticed, and a pretty plant of the Waterford variety, which Mr. Bain considers to be to the original what *Asplenium acutum* is to *Asplenium adiantum nigrum*. He only knows of one more plant of this variety in cultivation.

Fifth. In the same house in which are these boxes of Killarney Ferns is a fine plant of *Ruscus androgynus*, covering most of the back wall, and trained down several rafters. In this range, passing all others, we would instance as fine plants and interesting from their foliage alone, *Lomatia ferruginea*, a beautiful Proteoid, allied to *Teleopa*; *Protea cordifolia*, a fine plant with large rounded sessile leaves, and reddish stems of a somewhat pendant or trailing character, promising to make a good basket-plant; *Chamaerops humilis*, nice plants; good specimens of *Strelitzia reginae* punila, the flowers of which rise higher and show better in proportion than *reginae*; *Calophyllum inophyllum*, a hardwooded plant with beautiful leathery foliage, the reins going parally across from the midrib; *Cordyline indivisa*, a noble Yucca-like Lilywort, the leaves when full grown being 6 feet in length and 6 inches across; *Cycas revoluta*, and other Cycadee; a fine plant of *Xanthorrhoea hastilis*, which is a charming object, with its large tuft head of recurved, drooping, rush-like leaves, even without its tall pyramidal flower-stem; a new species of *Wildenovia*, with stems somewhat resembling *Asparagus* in their mode of growth—if anything, more interesting than *Wildenovia teres*; good plants of *Littæa grandiflora*, or *Buonaparte juncea*, alike beautiful in growth and beautiful with its pyramidal tall flower-stem; and the last we will mention here is the *Kingia australis*, a rush plant of much the same habit as the *Buonaparte*, with a strong short arborescent stem, and a large head of rush-like leaves, some standing upright, others nearly horizontal, and others depending, each individually and collectively far exceeding the *Buonaparte* in elegance and beauty—a picture worth going miles to see, and the only specimen we believe in these islands at present.

Of stove plants we will merely name a few of great size and beauty—*Draena draco*, *Urania speciosa*, fine large-leaved Musad; *Latania borbonica*, with huge leaves unbroken and uncracked; *Coccoloba pubescens*; *Scaforthia elegans*, the New Holland Palm; *Corypha australis*, Fan Palm; *Sabal Blackburniana*, &c. Among large specimens of Ferns were *Cyathea elegans*, *Doodia australis*, *Gleichenia flabellata*, very fine, and others; *Lonchitis aurita*; *L. pubescens*, very fine; *Dicksonias* and *Alphosias*, &c.

Among fine plants of Orchids we noticed several *Cattleyas* in bloom; also two large fine masses of *Epidendrum vitellinum* in flower; also a good number of *Oncidium*s, as *papilio* and others; a good *Phalenopsis*, several *Vandas*, &c.; and in flower in the colder houses were several varieties and species of *Blandfordia*, *Tritonia*, &c.

Sixth. We will now allude to three or four things which were in great plenty, but which, in general, are scarce even in good collections, and

1st, *Sarracenias*.—Of these there were a good variety, and in high health, as *purpurea*, *Drummondii*, *variolaris*, &c. The pots were mostly standing on moss. A moistish atmosphere suits them generally, but especially in summer. Propagated by division of the plants, best done in spring.

2nd, *Cephalotis follicularia*.—The stock of this New Holland Pitcher-plant is both fine and extensive. We noticed masses of it not less than 18 inches across; but these, though now looking like one plant, were formed by putting several plants into the same pot or basin. The soil seemed chiefly to be chopped sphagnum, peat, earth, broken pots, &c., and most careful

watering to apply plenty of moisture to roots and atmosphere when growing. This is freely propagated by dividing the roots into very small pieces, and there is hardly such a thing as the smallest bit refusing to grow.

3rd, *Dionaea muscipula* (Venus's Fly-trap).—In the same house with boxes of Killarney Fern were many plants in good order, the pots standing on damp moss in flats or pans. The treatment as respects soil seemed much the same as that recommended in the *Cottage Gardener's Dictionary*—namely, heath soil, sphagnum, and bits of potsherds. There, too, a casual mode of propagating it is referred to, by laying the leaf amongst damp moss; but Mr. Bain keeps up a good stock chiefly by leaf-propagation. "The leaf or leaves of spring growth are taken off with the petiole attached to it; that petiole, inserted as a cutting under a glass in the usual way, becomes in a short time furnished with buds along the margin on each side of the midrib, and these soon become little plants. Another mode and a good one (although much fewer plants are obtained), is when potting to take off the old part of the stem which is usually bare of leaves, and proceed much as in the case of the leaves. By these modes a plentiful stock may be kept up, and in a healthy condition in winter as well as in summer if the place is cool enough, as a warm greenhouse or a medium stove. In a warm stove it generally ceases to grow in winter."

4th, *Ouvirandra fenestralis* (the Madagascar Lace-plant).—Of this there was a good number of plants, good-sized and very small, and growing in tubs and pans without any tank, the plants being covered with water in proportion to their age and size. This is increased by dividing the roots into very small pieces. Almost the smallest nip seems, according to Mr. Bain, to possess a perfect organism for being developed into a perfect plant. Of course the less the bit the less the plant will most likely be. Some water-pans seemed to have erred so many dots just beginning to push. "It is grown in lumps of peat, and the water is renewed by flowing the pans over daily. Besides, we manage to draw off the water from the bottom of the pans two or three times a-week. We grew small plants at about 3 inches below the surface, and large ones from 6 inches to 8 inches, or even more; but in every instance it grows freely."

Such are a few of the salient points in this quiet retired garden of the College authorities. We left it with a feeling of pleasure mingled with regret that we could recollect so imperfectly the information so kindly and freely communicated by Mr. Bain in conversation. As to writing upon some subjects of general interest, he assured us he had no time for such work—that he really had nothing worth communicating, and, with characteristic reticence, considered himself only beginning to learn after all the years he had spent in gardening and botany—and that, besides, notices of some of the matters we alluded to had already been published. With our very limited means of reference we have failed to discover where—perhaps in botanical Transactions, or in the pages of some of the Irish farmers' journals, which devote a good portion of space to horticulture.

R. FISII.

THE MISTLETOE AND ITS PROPAGATION.

In your answer to "FELIXSTOWN," page 376, you advise the cutting of the bark to insert the seeds of Mistletoe. With due respect to your authority in such matters, allow me to say that cutting or wounding the bark for the insertion of seeds of this singular parasite was considered as hurtful rather than otherwise to its growing many years ago, when the subject of its artificial propagation was first mooted in the gardening world; and I have seen more than one plant reared without any incision in the bark of the tree it was grown on some twenty-five years ago. You will, I am sure, pardon my giving the views then agreed on as the supposed ones by which it was propagated in a natural way.

We all know the sticky, pulpy character of the berry; and as birds are fond of it, the conjecture was that they only partook of the pulp, but, flying away after each meal, rid themselves of the stony seeds sticking to each side of their beaks or bills by rubbing them right and left against the limb of the tree they alighted on, and the seeds sticking where they left them grew there if the character of the tree favoured their doing so. Many, of course, being planted on unsuitable bark did not grow, and some failed by some mishap or other; but, of course, a part grew. Now, there is no reason to suppose that the birds punctured the tree to insert the seed, then why should we do

so? in fact, the idea amongst practical men at the time I speak of was, that an incision hardened the bark and made it less agreeable to the Mistle-toe than when left alone, and I may I record one instance in which I know of a contrary course being attended with success.

A seed or two of the Mistle-toe was bruised a little and rubbed on the bark of an old Apple tree much moss-grown, but the seed was stuck on to the bark and not left to the danger of getting lost amongst the moss. Over the seed was tied a small bundle of thin muslin or erape, which remained on until it rotted off; this was to prevent the seed being disturbed by birds or other depredators, and nothing more was done. Time, patience, and a just observance of those laws which abide produce a Mul-berry or a mammoth tree, furnished the Mistle-toe plant in due course, and this was in a remote district many miles away from any known plant of a like kind. The process is a slow one, and the ardent propagator of the present day who turns on his new plants by the hundred the year after he receives the first cutting, would have his patience tried by the long time this parasite takes to effect a start. Its aftergrowth, however, was fast enough, and although I cannot say how far north this singular production flourishes, I can only say that some half dozen years ago I saw the finest specimens of it in Northumberland I ever saw in my life, and I have seen a good deal of Mistle-toe in the orchards and plantations in the neighbourhood of London.

Unfortunately, I may remark that the habit of destroying it in the latter locality is against obtaining large specimens; besides which, heavy snows, high winds, and other casualties befall it, that specimens above a medium size are seldom met with. It seems to grow as freely on a Lime tree as anywhere; but here the winds break it sadly. The stouter limb of a Maple is safer; but old scraggy Thorns and Apple trees are its favourite haunts, and I think the Mountain Ash allows it to grow, and some other trees; but I have never seen it on an Oak, but have heard of its being found so located at Eastnor Castle, and one or two other places.

While on this subject, I may say that I believe no one has succeeded in grafting this plant on the Apple—a practice that was several times attempted at the time the seeds were tried, the slow progress of the latter trying the patience of the less-persuading class of cultivators, to whose discoveries we owe so much and acknowledge so little.—J. ROXBOROUGH.

[We are very glad to receive this note and commentary; but there is no validity in the conclusion that because birds do not make holes in the bark to put Mistle-toe seeds in, that therefore the gardener need not do so. Birds do not tie a piece of muslin round the branch to keep the seed from being displaced, yet our commentator found that desirable. The tongue of bark we recommended to be raised and the seed placed beneath it, answers the same purpose as the muslin. That the tongue of bark not being separated at its base from the tree, as in an inverted A, does not become hard we attest from experience; nor if it did would it be of any consequence, for the radicles of the seeds penetrate the inner bark underneath the raised tongue. —EDS.]

ANNIVERSARY MEETING OF THE ROYAL HORTICULTURAL SOCIETY.

The Anniversary Meeting of the Royal Horticultural Society was held on Tuesday, 11th inst., Sir C. Wentworth Dilke, Bart., Vice-President, in the chair. There was not a large attendance of Fellows, considering the number now on the list, but those who were present appeared to take a lively interest in the proceedings. Amongst those present, besides the members of Council, were Alderman Copp-head, Alderman Wilson, Judge de Baresse, Mr. T. B. Saunders, Mr. T. Walcott, Rev. W. Griffiths, Mr. Robt. d'Osborne, Mr. W. B. Booth, Mr. Thomas Moore, Dr. Robert Dugg, &c.

After the advertisement for calling the Meeting had been read, Dr. Lindley, the Secretary of the Society, read the following Report:—

"A few short weeks ago the Council had looked forward to this Meeting as an opportunity for consulting the Society upon the prosperous state of its affairs. Now, though the lamented death of H. R. H., the President, their satisfaction has given place to sadness and gloom.

"The Fellows are already aware of the promptitude with which Her Majesty, with characteristic disregard of Her own feelings, at a time when She was overwhelmed with grief, deigned to think of the Society, which had been so specially the object of Her Royal Consort's care. The spontaneous

promise of support which the Queen has so graciously extended to it calls for no remark of acknowledgment.

"The Fellows have already been informed that, without loss of time, an address of condolence was awarded by the Council to Her Majesty.

"A further most gratifying demonstration of the Queen's purpose to do everything in Her power to support the Society, and carry out the intentions of Her late Consort, has since occurred. The Fellows are aware that at the present Meeting it falls upon them to elect their President and office-bearers. Had Providence not removed their late President, it would have been the privilege of this Meeting again to elect him. In consequence of his death, it became the duty of the Council, under prompt circumstances, they should recommend to the Society for election in his place; and they deemed it becoming to endeavour to ascertain Her Majesty's wishes on the subject. With feelings of the deepest gratitude the Council learned that had it been compatible with Her high position Her Majesty would herself have consented to it.

"In proceeding, therefore, to the Election of a President, as required by the Charter, it will doubtless be the anxious desire of the Fellows to meet the wishes of Her Majesty, who has been pleased to recommend the Duke of Kent, to whom, as the person who, under prompt circumstances, it would be most agreeable to Her Majesty's feelings to see holding that situation. The Queen has also expressed Her desire that though unable herself to hold the office of President, She may be kept as fully acquainted with the proceedings of the Society as she has hitherto been the case.

"Such encouragement and support, bestowed by the modes which have actuated Her Majesty, must strike a responsive note in every heart. The Council feel sure that the Fellows of the Society will with one accord participate in their desire to join with their beloved Queen in carrying out Her lamented Consort's plans, and so completing the noble monument which Her Majesty can offer to the illustrious Prince who did so much for it, and who had its welfare so thoroughly at heart.

"A statement of what has been done since the last Anniversary and of what remains to be done, will best show the Fellows how such intentions can be best and most practically effected.

"The number of Fellows of the Society at the last Anniversary (1st May, 1861) was 1752. Under the new Charter the date of the Anniversary has been anticipated, in consequence of which only eight months are now to be required. During that period 1675 Fellows have joined, of whom 365 pay 2 guineas and 75 by list of 40 guineas. The total number of Fellows on 1st of January, 1862, had reached 3774, composed as follows, viz:—

10 Fellows paying respectively	1 guinea
23 " " " " " " " " " " " "	3 "
6 " " " " " " " " " " " "	2 "
716 " " " " " " " " " " " "	2 "
915 " " " " " " " " " " " "	4 "
334 " " who have compounded by paying ...	20 "
355 " " " " " " " " " " " "	49 "

"At the General Meeting held on the 7th inst., 117 more Fellows were elected.

"The resolutions and details during the past season have been only 43. It will thus be seen that whether the number of Fellows be looked at as a whole, or a merely comparative view be taken of the increase since the 1st of May last, there is ample ground for satisfaction. The List of Fellows also shows that, irrespective of rank or title, the Society has the honour to reckon among its members a large proportion of the most distinguished men of the day.

"Whilst the adhesion of so many persons of eminence has been highly gratifying, the Council have never forgotten that the real and proper scope of the Society is the advancement of Horticultural knowledge. In all their proceedings they have acted strictly in conformity with the objects which they refer to the work done by the Fruit and Floral Committees; to the information contained in their published Proceedings; to the many interesting and novel subjects exhibited at their Flower Shows, as well as to the extent and beauty of these Shows themselves; to the mission of their Collectors to South America, the returns from whom are already beginning to arrive; and to their ballots for seeds and plants, as proof of their efforts to sustain the high reputation of the Society in this respect. Further improvements have occurred to the Council, which, as opportunities offer and means are found, will be ready to carry into effect.

"The statements of accounts appended to this Report being, in consequence of the alterations caused by the new Charter, only for a fractional part of the year—viz., from 1st May to 31st December, they cannot be looked at as a representation of the results of the year; nor can they be considered as such, either forward, as in most years, or in contrast and comparison with previous years. It is the partial commencement of a new epoch, and must stand by its lft as an imperfect record. From the same cause the accounts on the present occasion had to be prepared in a somewhat different form, inasmuch as they had been previously in the ordinary form. The Council had hitherto merely had to show the Society how its own individual accounts stood. It now has to produce a double set of accounts: one embracing the whole of its affairs, including those of Chiswick as well as South Kensington; the other confined to South Kensington. A separate account of the latter has to be kept for the Commissioners of 1861, as their rent depends upon the success of the Society. In the Appendix the accounts will be found stated in this double form. The first three accounts—called the Private Account, the Capital Account, and the statement of assets and liabilities—represent the affairs of the Society in its ordinary management; the fourth account, entitled the Revenue Account, has reference to the lease with the Commissioners alone. The accounts which will more directly interest the Fellows are those of Capital and Revenue—the Capital account as showing the amount of money which has been expended on the works in the Garden, and the Revenue Account as explaining the mode in which the funds of the Society are raised. On referring to the Revenue Account it will be seen that the chief source of income is derived from the sub-scriptions of Fellows. The Council feel that this is the mainstay of the Society, and that its prosperity must depend upon its possessing a sufficient number of regular subscribers. The result of the year is not, however, so satisfactory as it might be, although it does not yet retuse all they expect, gives very satisfactory promise of its soon reaching such a point as will put them at ease regarding it. The total sum derived from the Fellows as in all ways since the 1st May, 1861, has been £2877, but this includes £2374 paid for the purpose of which it has been capitalised or placed in a separate account, for the purpose of yielding a

yearly fifteenth to revenue. What had been paid prior to the commencement of the lease was carried to the general funds of the Society. The above receipts also include the whole year's subscription up to the 1st May, 1862, the subscriptions having hitherto been payable at that date, and thus one year's subscription applies to expenses in two year's accounts. This undesirable complication is the consequence of the change in the period of striking the yearly balance, rendered necessary by the New Charter, which rendered the accounts now to be balanced each year on the 31st December. The Council, in order to remove this inconvenience, have requested Fellows, in paying their next subscription, to pay only up to the 1st January, 1863, so that at that date the accounts may start fair, the year's subscriptions and the year's expenses both running for the same period.

"There is another matter which the Council are most anxious, if possible, to remove. It will be seen in the statement as to the number of Fellows and their different payments, that there is a certain number who pay retrospectively. These are Fellows who were elected at that period in the year when the subscription had not yet been paid in advance, were not called for until after the Fellow had enjoyed a year's privileges. It is long since this system was abolished, but 224 Fellows of the period remain. It would obviously be a considerable convenience in the working of the accounts if some arrangement could be effected with this exceptional class of Fellows, by the individual concerned, if he is not already so placed in the same position as others. It would make no difference in the amount to be ultimately paid by these gentlemen, because on death or resignation their past year's subscription would have to be paid, which is not the case with those who pay in advance.

"The next source of income is derived from the public by means of exhibitions and promenade, &c. The table, No. 5 of the Appendix, shows the amount obtained from this source during the past season, as well as the profit or loss resulting from each occasion. No account is there taken of the expenses of the public, the rent of the ground for exhibition, or other items which to a strict debitor and creditor account would be debited to the Society. But even after making allowance for this the result is satisfactory; with the establishment which the Society possesses (and must keep at any rate), these attractive entertainments have been provided for the Fellows not only without costing them any extra expense, but actually at a profit of £137 17s. 8d.

"The Council would wish, where practicable, to make every separate department of expense in like manner contribute to its own support. That part of the Chiswick expenses which is occasioned by the operations of the Horticultural Committee, they make it their duty to defray, the sale of the fruit and vegetables raised for trial purposes; and it will be seen that £195 1s. 2d. have been received during the last eight months from this source. In the same way they would wish to make their publications contribute to the cost of producing them; and they intend that, like those of other eminent Societies, their "Proceedings," &c. be sold to the public. With the view of rendering them more attractive, it is proposed that illustrative plates be occasionally given.

"Of the items of expenditure, the only one which occurs to the Council as calling for comment is the interest on the debentures. This was originally 5 per cent. Since a certain bargain was made, however, the Society has expended from the funds drawn from its Fellows, a sum of nearly £20,000 beyond what has been borrowed, on permanent improvements to the Garden. In July, 1859, when the loan was brought out, the number of Fellows was 274, and now £24,000 has been expended. The interest on the loan at the time was come at which they might propose to the debenture-holders either to pay them off or to reduce the rate of interest to 4 per cent. Four-fifths have consented to the reduction, many of them handsomely simplifying their approval of the step. The remaining fifth has been paid off, by transferring its bonds to fresh applicants.

"The Capital Account shows the sums that have been actually paid for the works in the Garden; and in the Account of Assets and Liabilities will be found the additional sums incurred or expected to be due. A portion of the expense of the works is not payable until twelve months after their execution.

"That part of the Garden Works, the execution of which falls upon the Society, is nearly completed. The conservatory, the council-room, the terraces, the various terrace-steps, and terrace-walls, the band-houses, the basins and canals, the Artesian well and water-works, the laying out of the Garden, are all finished or far advanced. The portico leading from the council-room into the Garden, and the space adjoining it, has still to be plastered and finished. The walks are not so finely gravelled as is intended. Some minor works originally contemplated are still kept in view, and probably some of them will be executed upon them or fitted into them. The Society has already felt the benefit of these two sources of embellishment. Various works of art lent to the Society will be found decorating the Garden, and some of the objects intended for the International Exhibition will find their way into its precincts. Others of a higher class have been lent to the Society, and will be seen in the decorations of the Garden, and in the noble works of art presented by Her Majesty, now placed in the conservatory.

"The Fellows themselves have done more to furnish the conservatory with plants by their gifts than the Council by purchases. Many of these are of great value and beauty.

"The New Charter has rendered necessary a new body of Bye-laws, which will be brought forward for adoption at an early opportunity.

"The arrangements for the year 1862 have been already circulated among the Fellows and need not here be repeated. The most important proceedings regarding them are perhaps—1. The arrangements with the Commissioners of 1862 for the issue of joint tickets, admitting the owners both to the International Exhibition and the Society's Garden. The price of these has been fixed at five guineas. Fellows of the Society will, however, only require from the Exhibition Commissioners a ticket for the Society's Garden at 2s. and—2. The arrangement with the Commissioners of 1861 for an entrance to the Garden during the Exhibition season from Kensington Gore, through the Commissioners' ground behind the conservatory."

THE CHAIRMAN, in moving the adoption of the Report, referred, in a few and appropriate observations, to the lamented death of the Prince Consort, who, had he lived, would on this occasion have filled the position which he (the Chairman) now so inadequately occupied. As stated in the Report of the Council, Her Majesty would herself have accepted the office of President of the Society, but her legal advisers had suggested that the duties of the office would be incompatible with those which she exercised as the Sovereign of the country. He (the Chairman) had had a few minutes' interview with Her Majesty, and she stated to him that she was most anxious to do all in her power to promote the prosperity of the Society. At the same time Her Majesty was pleased to suggest that the Duke of Buccleuch should be elected in the place of the deeply-lamented Prince, and which suggestion he (the Chairman) felt perfectly satisfied the Fellows of the Society would carry out. Referring to the Report of the Council, the Chairman expressed a hope that the 250 Fellows who had at present paid retrospectively would pay up as others had done. In the arrangements for the coming year the Society had announced not only three great exhibitions, but others of a minor character, with the view of attracting the public to the Gardens. The International Exhibition of Roots and Cereals to be held in October would, he believed, be a great success, and would not clash with the Exhibition of the Royal Agricultural Society to be held in June at Battersea; and various foreign countries, including Austria, Wurtemberg, Russia; and others had expressed, through their Commissioners, a desire to co-operate with the Society in the exhibitions. He then formally moved the adoption of the Report.

After several inquiries relating to the arrangements existing between the Society and the Commissioners of the Industrial Exhibition, as to admission from the Gardens to the Exhibition building, all of which were answered satisfactorily, Mr. Alderman Wilson seconded the adoption of the Report, which was carried unanimously.

In accordance with the wish of Her Majesty, the Meeting unanimously elected His Grace the Duke of Buccleuch President of the Society.

Dr. Lindley was re-elected Secretary.

The Meeting then proceeded to the ballot for the office-bearers of the current year. Lord Somers; Mr. John Fleming, gardener to the Dowager Duchess of Sutherland, Clereden; and Mr. Robert Cooper, of Cooper & Bolton, Fleet Street, were elected in the room of Mr. H. T. Hope; Mr. Edmond, gardener to His Grace the Duke of Devonshire, Chiswick House; and Mr. Robert Wrench, of J. Wrench & Sons, London Bridge.

REGULATING NEGLECTED WALL FRUIT TREES.

FROM the description your correspondent "T." at page 374 of the present volume of THE JOURNAL OF HORTICULTURE, gives of his trees, I am afraid from all the shapes he can try, he will never have any satisfaction from them, unless he can grow them over again the very same way he would a common Laurel. I can with confidence recommend this plan with Plum trees. I never tried any other kind of fruit tree the same way, but if I had your correspondent's trees I would not hesitate to give one or more of each sort a trial. About three years ago I had charge of a lot of Plum trees, as perfect specimens of bad training as possibly could be, and almost barren. They were healthy, and I was unwilling to cast them away; and to let such grotesque-looking and useless rubbish remain as they were was out of the question. I cut a few of them within 6 inches of the ground, leaving 3 inches of the graft. They succeeded far above my expectation, every one put up a mass of shoots. I had to thin out a quantity of the small spray. I kept them regulated and fastened to the wall; in autumn I lifted them, and root-pruned them. This prevented too luxuriant growth the following summer, and they formed a number of nice little spurs on the first year's wood. I cut down a few more last year with equal success.—J. ANGUS, *Edinboro*.

TREES ADAPTED FOR SEA-SIDE PLANTING.—A correspondent, who has planted largely on the Norfolk coast, informs us that he has found the following trees succeed better than any others in resisting the sea blast:—*Populus alba*, *P. nigra*, *P. angulata*, *P. macrophylla*, *Hippophae rhamnoides*, *Pinus pinaster*, *P. halepensis*, *P. brutia*, *P. laricio*, *P. maritima*, *Quercus ilex*,

Q. Lucombeana, Q. Cerris, Fagus sylvatica, Alnus glutinosa, Ulmus suberosus, U. montana, U. campestris, Acer pseudoplatanus, Ilex aquifolium; and that the common Oak, Lime, Horse Chestnut, Walnut, and Larch succeeded worst of all. —(*Essex Gazette*.)

TURNING OUT CUTTINGS OF ROSES IN POTS. VINES IN PROPAGATING-HOUSE.

I HAVE 100 ROSES in small three-inch pots, consisting of Bourbons, Teas, and Chinas, which I struck last autumn. I have them on a shelf in my propagating-house (which is cool just now). Now, having all my bedding stuff in it, and as I wish to get up a little heat soon to begin to propagate, and, consequently, shall require all the small pots I can lay hands on, would you recommend me to plant out the Roses now in a place where they could be sheltered with mats and hoops, if frost should come on? They are beginning to grow away.

My propagating-house is a lean-to 18 feet long, 10 feet broad, 5½ feet high in front, and 10 feet at back. In summer I grow Pelargoniums, Fuchsias, Balsams, and other common things. Could I do anything with Vines in it at the same time, with the temperature that would suit the plants above mentioned (normal heat), and what hardy sorts would you recommend?—A. McCALLUM, *Dumbartonshire*.

[We think in your position it would be best to turn out the plants as you propose, until the end of March. If the plants have a little ball and are turned out into rough leaf-mould, they will never feel the moving. You might have three Vines in the propagating-house, and Black Hamburgh and Royal Muscadine would be best; but, of course, they will shade your plants in summer; but the Fuchsias and Geraniums might do as well under a protection of thin calico out of doors then. Balsams and other annuals would do well, and so would Fuchsias in the open spaces.]

We cannot say more about expense than has already been stated. We presume that the expense of heating is what frightens your master, and your north hipped-roof of glass will increase that in your place. For such a ten-foot wall, and some 11 feet of a border, we put up a house this spring—height of front on posts, 3½ feet, the length 65 feet, the glass and the wood of which cost under £20. We are not certain as to the glazing and painting. All these things depend much on the neighbourhood. The wood was cut and planed by machinery, so as not to waste an inch, and the glass was 16s. per 100 feet.]

OSAGE ORANGE—INDIGOFERA DOSERA AND OTHER PLANTS.

I AM glad to see a north-country correspondent report the doings on the southern side of the border, and hope his inquiries will be duly responded to by some better able to give a reply than I am. As the district from which your correspondent writes (Cumberland), is far from devoid of interest, and for natural beauties, if not productions, is second to no county in England, the botanist, I believe, will regard the plants found on Helvellyn as important a feature in his herbarium as those gathered in the most fertile valley in the kingdom. And Fancy brings me back to the happy years of early life there, amongst other wild plants gathered amongst patches of snow on Cross-fell, one of the Lycopodiums of more than ordinary sturdy growth attracted my attention; I believe it was called *L. selago*, the specific name having long since given name to a genus. On the damp recesses of these mountains that interesting little plant, *Saxifraga oppositifolia*, is also found; but I was never so fortunate as to light upon it. But my purpose is not to describe the botanical features of this elevated region, but to express a hope that such correspondents as the one signing himself "GROUSE" will frequently report how gardening matters go on in the land of hills.

Horticulture of a superior kind is certainly not confined to the counties bordering London or the densely populated districts; for I have visited many gardens in England, and some of them justly esteemed for their excellence, and yet I have never seen such a fine house of Orange trees as I remember seeing some thirty years or more ago at a gentleman's seat-house near Penrith. Time works wonders in many things, and perhaps

these Orange trees may have endured the vicissitudes of adverse time; but if an onward course of prosperity has attended them they must now be noble specimens.

I am sorry I cannot give your worthy correspondent any advice on the plants he speaks of. I had some plants of *Indigofera dosera*, but they were so infested with red spider that I threw them away. The Osage Orange I have grown, but it is certainly not worth the attention it was by some recommended to bestow upon it. Its bright shining leaves look well in summer; but I have never seen the least inclination for flowering, and in winter it much resembles a Gooseberry bush, the tips only not being ripened. I have seen a tolerably good hedge of it, but not better than an ordinary quickset, and I expect it will not be so convenient when cutting time comes round. I am not acquainted with *Calceolaria violacea*; but supposing it to be a species, I am sorry our hybridisers confine themselves to such narrow bounds. The old *Calceolaria arachnoidea*, a deep purple-coloured variety, has long ago passed out of cultivation. Perhaps some correspondent, like our Cumberland friend, might run against it in some secluded spot. Only, whoever finds this, or any other ancient curiosity, will, I hope, issue it again under its proper name, and not rechristen it as the *Gazania rigens* was.—F. G. II.

ONE-SIDED STRIPED BORDERS.

HAVING at page 401 described several plants as being suitable for ribbon-border purposes, I herewith give a few examples of planting as much with a view of informing the inexperienced what not to plant as to give a successful example, as those here given were not in all cases such as I would have chosen had abundance of other things been at hand; but being the last variety planted, when many of the more useful plants were exhausted it became a matter of necessity to make the respective borders up of such things as could be had. I also give them just as they were planted, with all their failings pointed out. It is also proper to say, that the borders here mentioned are all of one feature—i.e., one-sided, facing a walk, in most cases a row of alternate Dahlias and Hollyhocks formed the back. The situation being certain walks crossing the kitchen garden; and in the cases where the front edging was composed of *Arabis variegata*, that plant is a permanent feature there. Arches at convenient distances apart spanned the central walk, over which were trained some fancy Gourds. The striped borders being on both sides, and the changes of planting only occurring where there was a stop or break in the walk, this rough outline may suffice to explain all that is necessary in a general way. I now give the examples, all of which consisted of four rows of plants.

No. 1.

- 1st row, *Arabis variegata*, yellow and green.
- 2nd row, *Geranium Tom Thumb*, scarlet.
- 3rd row, *Calceolaria viscosissima*, yellow.
- 4th row, Dwarf *Dahlia Zelinda*, purple.

Dahlias and Hollyhocks at back.

This arrangement was pretty good, the plants presenting a uniform rising bank, and when in flower looked well; but the dry weather in August told on the *Calceolaria* and dwarf *Dahlia* towards the end of that month, still the arrangement could not well be improved.

No. 2.

- 1st row, *Arabis variegata*.
- 2nd row, *Geranium Lacinium* major, pink.
- 3rd row, *Calceolaria rugosa*, yellow.
- 4th row, *Dahlia Zelinda*, purple.

Dahlias and Hollyhocks as before.

This was very indifferent, the *Geranium* out-growing the *Calceolaria*, and to have reversed these would have placed the *Calceolaria* by the side of a variegated plant, the *Geranium* being planted in mistake for a dwarf one of the same colour; and the *Calceolaria* instead of *C. salviaefolia* spoiled this border.

No. 3.

- 1st row, *Arabis variegata*.
- 2nd row, *Gazania rigens*, orange.
- 3rd row, *Perilla nankinensis*, maroon.
- 4th row, *Chrysanthemum regale p. cna*, yellow.

Dahlias and Hollyhocks as before.

If General Tom Thumb had been planted instead of the *Gazania*, this would have looked very well. As it was, the *Gazania* was too low and not enough of flower on it to fit it for a striped border plant. The *Perilla* and *Chrysanthemum* answer admirably together.

No. 4.

- 1st row, *Arabis variegata*.
 2nd row, *Geranium Blaze*, scarlet.
 3rd row, *Geranium Boule de Neige*, white.
 4th row, *Perilla nankinensis*.
 Dahlias and Hollyhocks as before.

When the *Geraniums* were in flower this looked not amiss, but there is never sufficient bloom on a white *Geranium* to rank it as a white plant. A variegated one would have been better if it were tall enough. In heights, those planted did very well, but in a ribbon-border a distinction of plants seems as requisite as difference in the colour of the flowers. The above was, therefore, not good.

No. 5.

- 1st row, *Arabis variegata*.
 2nd row, *Lobelia*, a pale blue variety.
 3rd row, *Calceolaria striatifolia*, yellow.
 4th row, *Salvia fulgens*, scarlet.
 Dahlias and Hollyhocks as usual.

This not amiss, only the *Calceolaria* suffered during the dry weather, and ceased flowering entirely after the middle of September, the situation being drier than that of most of the others. The *Lobelia*, a strong-growing one, flowers well from June to November. *Salvia* does pretty well.

No. 6.

- 1st row, *Arabis variegata*.
 2nd row, *Calceolaria Prince of Orange*, intermediate colour.
 3rd row, *Verbena Purple King*, purple.
 4th row, *Geranium Crise Unique*, rosy scarlet.
 Dahlias and Hollyhocks as before.

This very good while the *Calceolaria* was in flower, which was a considerable part of the summer; but like the *Calceolaria* in No. 5 it began to fail when prolonged dry weather told on it. This example presented as great a mass of bloom as any, and the plants kept pace with each pretty well.

No. 7.

- 1st row, *Arabis variegata*.
 2nd row, *Geranium Shrubland Pet*, red.
 3rd row, *Geranium Flower of the Day*, variegated.
 4th row, *Perilla nankinensis*, blue-rose.

This looked very well, and it is very creditable. Both the *Geraniums* have ceased flowering, but the contrast of the small Oak-leaved variety, *Shrubland Pet* with *Flower of the Day* is excellent, and the latter backed by *Perilla* presents a better appearance at the present time than any other example of the kind. The fact is that *Variegated Geranium* and *Perilla* are the very best plants out for striped borders.

No. 8.

- 1st row, *Arabis variegata*.
 2nd row, *Calceolaria bicolor*, yellow and brown.
 3rd row, *Verbena Purple King*, purple.
 4th row, *Geranium Trompe Mont Hoage*, pale-flowered.

The *Calceolaria* being a half-herbaceous one did not keep up that succession of bloom necessary for prolonged beauty, and the pale flowers of the *Geranium* were never at any time numerous enough to entitle it to distinction. The *Verbena* did very well, but altogether the example fell far short of that of No. 7 for general effect.

No. 9.

- 1st row, *Double White Pink*.
 2nd row, *Geranium Lady Holmesdale*, a pink variety.
 3rd row, *Calceolaria integrifolia*, old yellow.
 4th row, *Ageratum mexicanum nanum*, pale blue.
 Dahlias at the back.

I expected the *Calceolaria* would have kept pace with the plants on both sides of it, and it did so for some time, but eventually the *Geranium* overtopped it; and the *Ageratum* and *Geranium* met by the end of September forming not a bad contrast. The permanent feature of the pink plant is not bad as a front plant, and had *Calceolaria viscosissima* occupied the place of *C. integrifolia*, this would have been one of the best examples, but I only obtained the last-named *Calceolaria* last year; and, believing it as the old original species to be likely to do better in dry seasons than the improved varieties now in use, I planted it as above on trial and have been miserably disappointed.

In conclusion I may say that the bulk of our variegated *Geraniums*, *Cineraria maritima*, and *Variegated Alyssum*, was planted in more important places than those given above, and formed some better examples in the striped-border way, which will be described hereafter, and most of them look well up to the present time. I hope some other planters will favour us with the result of their experience in this line, and also give some cases where the flowers face both sides, forming a ribbon-border of what we may call a span-ruled description, instead of those of the lean-to kind which I have given; but as

I have several of the others of from 3 feet to nearly 20 feet wide, all more or less good, which, however, may be described in a future article.

J. ROBINSON.

LONGFORD HALL.

(Continued from page 354.)

RETURNING from the Cucumber-house I passed the potting and tool-house 50 feet long by 17 feet wide. No expense has been spared to make this as complete and useful as possible. The roof is nearly all glass, thus making it so light that the gardener has put up a stage on one side and placed on it a considerable number of store-pots of bedding-out plants—such as *Scarlet Geraniums*, *Calceolarias*, &c. The frost is kept out by a double row of hot-water pipes. The boiler and fireplace for it are in a separate shed, so there is no gas arising from the hot ashes to injure the plants or the lungs of the young men when engaged in potting. This house is so spacious that there is plenty of room for benches, soils, and plants, when potting is being done. The tools are arranged in different compartments, with inscriptions on each to show where each kind of tool should be placed—such, for instance, as hoes, rakes, riddles, baskets, scythes, shears, hammers, &c. In the centre I noted a placard in large letters announcing the rule, "A place for everything, and everything in its place." And on another—"Clean your tools." Altogether I cannot help considering this potting and tool-house the best I have ever seen. The principle of order, even in places comparatively out of sight, must instil that idea into the minds of the young men employed there never to be eradicated hereafter.

Adjoining this house there are a cooking and eating-room for the men, and adjoining that a spacious fruit-room 75 feet long and 17 feet wide. The fruit is laid on trellised shelves all round it, and appeared to keep very well. Some Nonpariel Apples were particularly good. To prevent damp arising, the floor has had a covering of asphalt laid on it, which makes an excellent floor indeed—not only in keeping the room dry, but also preventing rats and mice from harboring there. Next to this noble fruit-room are the lodging-rooms for the under-gardeners. I peeped in through an open window, and observed that they were a good size and well furnished, very different to the bothys I was lodged in when I was an under-gardener. Many a larger place might copy from this example, and thus improve the comfort and health of the young men employed in the gardens. At the other end of this range of rooms and sheds there is a long, wide, open shed for to dry soils and keep garden-pots, wheelbarrows, and mowing machines and rollers. This is much better than placing such cumbrous tools in the open air, as it too generally done.

Near to this open shed is the entrance to the Mushroom-house. Corresponding with every other department, it is of immense size—namely, 156 feet long and 13 feet wide. This house is, in fact, a vault arched over with bricks. There are three shelves on each side. When I called there early in January, the three shelves on one side were entirely filled with *Rhubarb* roots, which were producing fine stalks as thick as they could stand. On the lowest shelf, or rather ground floor, I noted that it was devoted to forcing *Sea-kale*. The remainder of the shelves was occupied with *Mushrooms*, which were coming up in great profusion. This house is lighted with gas, when light is needed. It was lighted when I saw it, and it had certainly a novel and striking effect. The beautiful pink and red stalks of the *Rhubarb* and the white-capped *Mushrooms*, seen by a double row of gas-lights, was a truly singular and pleasing sight.

Such a place for forcing *Rhubarb* and *Sea-kale* is far superior to the common method of forcing by covering the crowns with pots, and then covering the pots with a piled-up heap of stable-dung or leaves—both unsightly objects in a well-ordered garden. From this interesting place I walked to two pineries placed at the east end of the range of vineries and Peach-houses at a right angle with them. They are span-roofed, placed side by side, are each 63 feet long and 17 feet wide. The first is devoted to succession plants, and the other is a fruiting-house. The path of the first is in the centre, and on each side are two pits. The bottom heat is attained by hot-water pipes running under the pits in a chamber, and over them is a floor of strong slates, or, more properly, thin flags. The plants are grown in pots, and are plunged in a bed of sand, which is considered far superior to

bark, being more lasting, less troublesome, and affording no harbour for worms and woodlice, and besides these advantages it has a neat and cleanly appearance. To give top heat the pipes are laid on each side of the walk, and that is found quite sufficient to heat the house sufficiently for succession Pines. In the fruiting-house the pit is in the centre, and the paths run on each side, and the pipes to give top heat are next to the walls. They are covered with bricks set on edge, with pigeon-holes to let out the heat, and on the top is a stone shelf, on which I saw a large number of Vines in pots now breaking, and showing plenty of bunches, which are uniformly reduced to ten bunches on each Vine. Mr. Adams considers that a sufficient number, and I think so too. Most gardeners would be thankful for such a number on early-forced Vines in pots. Between the Vines I saw Kidney Beans in pots in flower.

The fruiting plants stand in five rows, twenty-five in a row, thus giving one hundred and twenty fruits, of which number one-third at least were in fruit in different stages of growth. Some Montserrat were just ripening, and were well-swelled, handsome fruit. Of that handsome large kind, the Black Prince Pine, I saw several nearly swelled up to their full size, finer fruit I never saw at any season. These two Pine-stores are the best for the purpose I have seen anywhere. To a gardener who loves Pine-growing, the sight they afford is worth going a long way to see.

Crossing the kitchen garden, which is about two acres in extent, we come to the pleasure-ground. To the right is a lofty wall, built, no doubt, to hide the back buildings attached to the mansion, and in front of that wall is a raised broad terrace covered with glass. It is 130 feet long and 8 feet wide, forming a pleasant promenade in wet or cold weather. Next the front glass there is a platform, and on it I noted a row of young specimen Heaths and New Holland plants. Somebody has displayed a considerable amount of skill and patience in training these plants. I have seen young specimens preparing to make exhibition plants by most of the successful exhibitors at the metropolitan shows, but even these experienced hands could not have done their plants better than those I saw in this promenade. At the end of it came to a large glass-covered structure 66 feet long by 44 feet wide. The roof is what is called ridge-and-furrow—the only way by which a large space of ground can be covered with a uniform height of roof. This house is to be furnished with fruit trees in pots, which will render it, in fact, an orchard-house. It is adjoining the conservatory, and that adjoins the mansion: therefore, to make it look pleasant at this time of the year, it is partially filled with large Camellias, Orange trees, standard Bays, standard Laurustinus, and such like. Near the border of the walks I noted forced flowers, such as Cressets, Hyacinths, Lily of the Valley, and Chinese Primroses. Here, again, the Vine is not forgotten. Every pillar has its Vine, and every Vine has made strong wood. In the season there must be an immense weight of Grapes produced at this place.

The conservatory is one of those lofty buildings erected more as an architectural embellishment to a dwelling than a fit habitation for plants, excepting for creepers and climbers—for such plants no place can be better. To furnish such a conservatory a large quantity of plants grown in other houses is necessary. Here I noted most excellent Chinese Primroses of the fringed varieties in full bloom, also good Cinerarias, and other winter-blooming plants. Camellias well set with buds were just beginning to expand the most forward, and in a short time will be covered with bloom.

I certainly enjoyed this visit to Longford Hall gardens, and trust my description will interest the reader as well as I was in recording what I observed there.—P. APPELBY.

THE SLIPPERY ELM.—One of the most valuable, as it is a well-known article in our country (says an American journal), is the Slippery Elm (*Ulmus fulva*). All our apothecaries keep it, both the flower and the bark. It is generally called either the Slippery Elm, Red Elm, or Rough-leaved Elm. It is indigenous to our climate, and what is remarkable (though but little known), it contains a great amount of human nourishment. It is medicinal also. It is an excellent substitute for water, and you can carry in your waist-coat pocket sufficient to subsist on for "ten days." The shipwrecked sailor, the soldier in Mexico, and the traveller in the prairies, should never be without it. It always mitigates hunger, and is nourishment and drink. Let no slip go to sea without it—no traveller fail to have it with him—no army march without it.

SUMMARY OF METEOROLOGICAL OBSERVATIONS.

HORTON HALL, BRADFORD, YORKSHIRE. (Latitude 53° 47' 36" N., longitude 1° 44' 47" W. Height above the sea level 496 feet.)

Means
Total.

* The average of the ten preceding years.

January.—This month up to the 21st was cold, but not remarkable for extremely low night temperatures; on the contrary, for twelve of the first twenty-one days the thermometer had a mean reading 31°; whilst the nights were only 4° colder, or 27°.

The rainfall was nearly 1 inch below the average, and the greatest amount that fell on any day of the month was '68 inch on the 1st. The mean temperature was 3° below that of January, 1860.

February.—A remarkably wet month; 1·07 inches fell on the 8th, and 1·98 inch of rain and snow fell on the following day (9th), which, along with what fell on thirteen more days of the month, was the wettest February experienced in this locality during the last twelve years. Notwithstanding the unprecedented amount of rainfall, the moisture of the atmosphere was not so great as January was by 7°, perhaps owing to the infrequent prevalence of fogs. The mean temperature was 8° warmer than February, 1860. On the evening of the 21st, and morning of the 22nd, a very strong wind prevailed; it came from S.W., and had a force of 20 lbs. on the square foot.

March.—This month was the wettest ever recorded here. It rained more or less on every day except six days, and snow fell on one day when no rain fell, therefore, there were only five fair days; hence the proverb of the ancient sages was verified:—

“A bushel of March dust is worth a king's ransom.”

A thunderstorm passed over without heavy rain on the 5th, but 0·18 inches of hail fell; it rose from the west, and, what was most remarkable, a strong gale was blowing at the time. The heaviest amount of rain fell on the 4th, — 0·94 inches. The mean temperature was 3° higher than March, 1860.

April.—A fine month, but very little rain, frost, or extremes of heat or cold were experienced. The days were colder than usual, and the nights warmer—frost prevailing on three nights only; nevertheless, the mean temperature was 2° 4 above that of April, 1860, but the temperature of the earth was 1° below the average at 1 foot deep.

May.—This was a dry month, the driest of the year. (Query, Is May generally the driest month of the year?) The rainfall was deficient by rather more than 1½ inch, and the greatest amount that fell on any day during the month 0·18 inch on the 25th. The mean temperature was exactly equal to that of May, 1860, being 1½° below the average.

June.—A grand contrast to June, 1860—a temperature equal to the average. The days 6° warmer, nights 4° higher, besides 4·95 inches less rain, and more than double the sun or less amount of cloud than June, 1860. The rainfall was half an inch below the average; and although thunder was heard, on one, lightning was seen but no thunder heard on three, and thunderstorms occurred on three days of the month, yet the greatest fall of rain was only 0·45 inches on the 21st.

July.—A fine month on the whole, but not equal to the average. The mean temperature was 2½° below the average, and only 1° warmer than June, 1860. Rainfall half an inch in excess of the average, and that which did fall fell not in large quantities, but in small portions at a time; so that the month was showery, not wet, and every way a month that promoted growth.

August was a fine month. However, the temperature was 2½° below the average; but the days were 4° warmer, and the nights 3½° than August, 1860. The temperature of the earth was 2° below the average. There was also a deficiency of the rainfall.

September.—The amount of rain was 2 inches above the average, and rather more than half an inch fell than had done during the last twelve years. The greatest amount fell on the 6th—1·05 inches. More rain fell this month than in the corresponding month of last year by 1·93 inches. The temperature, however, was more genial—it was 4° warmer than September, 1860.

October.—The driest and warmest month during the last twelve years. There was a thunderstorm on the 11th, when 0·41 inch of rain fell. The month was 3° warmer on the days, and 2° at nights than October, 1860.

November.—The wettest November since 1852, when 6·54 inches fell, or nearly 2 inches more than fell this year. The days were 2° warmer, and the nights 3° colder than November, 1860; therefore, the mean temperature this year for November was 1° colder than November, 1860, and 3° below the average.

December.—This month was 4° warmer than December, 1860. Less rain also, by 1·15 inches. On the whole a seasonable month.

The year was an average one, excepting the rainfall was considerably above the average; but there were less rainy days by thirty-seven this year than there were in 1860, and 4·42 inches less rain fell. The range of temperature this year being 68°, whilst that of last year was 71°.—GEORGE ABBEY, *Gardener, Horton Hall.*

ICE-STACKS VERSUS ICE-HOUSES.

WORTHY Mr. Robson seems to think he has vanquished the ice-stacking party—successfully combated the principal issue to the attainment of which their stacking led: therefore I feel bound, by the very defensibility of the mode as propounded by me in page 335 of this Journal, to buckle-toe in the pleasing task of endeavouring to further elucidate a subject which has called forth a greater number of friendly combatants than any subject in my memory has done for some time past in this highly instructive *Progressing Journal*. A hour upon the principle of the one at Lord Jersey's, as recently illustrated by Mr. Bailey of Nuneham last week, is an entire embodiment of my views on ice-keeping below ground. I knew the house well when the late lamented Mr. Batchelor lived there; and what is there in those views of ice-keeping below ground that is not embodied in my views on the same subject above ground, save that I am a more liberal advocate of what are there called the necessary requirements to success?

Mr. Robson having so gallantly taken his stand upon our (the ice-stacking party's) ground, we will endeavour, as we feel bound, to defend our views in as moderate a manner as possible. And first, permit me to correct an error, Mr. Robson having misunderstood my article when he concludes that I mean the walls to be made with best wheat straw. I believe I there stated that any old thatch would do, presuming the reader would draw the inference that any straw not being too rotten would do. Were I going to construct another stack, I should prefer barley straw thrown in indiscriminately. As regards being straight, I only wish to have wheat straw immediately between the ice and hurdles, simply because there it would be more or less wet, and the stronger the straw the better would it withstand the same. I do not wish the outside of the straw wall to be thatched. I simply mention, I throw a little straw round the outside—my object being to have a good thickness of straw thrown on the stones (the drainage for air and water), to keep the air from entering too directly upon the ice. For instance: If the platform I mentioned be formed of stones, to support these stones (a quantity of them will roll beyond the limits of the square), you require the straw within the hurdles upon the edge of this platform. If not quite sufficient, I would lay a ridge of straw all round, leaving a foot or two of the farthest stones there to admit the air.

I have above expressed my views with reference to the better way of keeping ice without regard to economy; my object in my late article being, as I before stated, an endeavour to extend the number of those who preserved the same. But I will take Mr. Robson's views, and refer to them under the several heads he lays down. First, *Convenience*. It must, I think, be more convenient to tip a load of ice direct into its bed, there to break and ram it, than to tip it down outside of the door of the old ice-house, there break it in (if the slightest thaw) the dirt outside the door, thence wheel it in through the passage afterwards to ram it down. In getting a barrowful with Mr. Robson last week, I quite expected he would have taken a fork with him to remove the litter from the surface of the ice, my never having seen ice placed in a house without a lining of straw all round and over it, the same having to be removed, as in my stack, each time ice was required, not in such quantity—yet the fingers, as a rule, had to be used when the thickest was removed, to draw a mass of wet dirty straw off the surface. It is useless for us practical men to refer to the trouble of removing 2 feet of straw as being an object. The fork is in, and the ice laid bare, clean, and almost dry in the time it takes to light the candle for the house alone. A couple of barrowfuls are got and the straw replaced most easily in ten minutes. Again, we have here as extensive an establishment as any, with the exception of almost regal palaces. Things are kept always upon ice, having no less than three refrigerators in constant use. This I could not do were I dependant upon our so-called old ice-house in the wood, as it is at present constructed.

When writing my original article upon this subject, I considered that even the humblest homestead could furnish the materials necessary for my rustic ice-preserver; yet I will not rest its claims upon this, but will proceed to draw practical consequential propositions upon the relative cost of the two I will not attempt to explain the expenses attendant upon the old ice-house, but will take Mr. Robson's primitive quotations as to the quantum of bricks alone required—namely,

On the other hand, for making an ice-stack—

4 posts	20 10
20 hurdles of 18 each	1 0
2 loads best wheat straw for thatch	5 12
4 loads coarse wheat or barley straw for hurdles	4 0

£9 2 Ans.

For £10 I should be enabled to build a most efficient one of the sort. But, as I before remarked, the whole can be had upon even a farm of any pretension whatever. And I state emphatically that here the expense ends, other than perhaps a load of wheaten straw once in seven years. It does not require making afresh every year. The load of straw, which is necessary in every ice-house, when the ice is all used it is placed upon that already within the hurdles, and that one load each successive year is all that is wanted. As no wet can get to the materials, they last an indefinite time.

In my deductions herein I have kept strictly within the limits of practice, and I hope not without an object. The materials are within the reach of all, as above; the labour is little—the best explanation is a *trial*.

In conclusion, I beg to express my high gratification at the tone of the correspondence upon this subject. Mistakes have been rectified, and opinions opposed with the most unmistakable good feeling. Herein consists the pleasure of communicating our views to others.—W. EARLEY, *Digsell House, Welwyn.*

SETTING THE BLACK DAMASCUS GRAPE.

SOME gardeners find a difficulty in getting the Black Damascus Grape to set well—so much so, that they have been communicating their failures to various gardening periodicals, and some, from their succession of failures, intend to eradicate it from their collection altogether. Mr. Dick, gardener to Lord Vernon, Sudbury Hall, finds no difficulty in getting it to set well. He had some beautiful bunches on a young Vine last year, with large, regular, well-shaped, well-coloured berries. Mr. Dick keeps rather a dry atmosphere, and gives the bunches one or two slight shakes when they are in flower, which disturbs the pollen, and thereby assists nature in communicating its fecundating principles to the stigmas. If done at the right time, equal-sized berries and symmetrical bunches will be the result.—G. U. R. J.

[Your other communication we hope to publish next week.—*Eds.*]

SOWING MISTLETOE SEED.

IN reference to your advice respecting the propagation of the Mistletoe, I have tried the plan recommended—namely, tonguing the under part of a branch of an Apple tree, and inserting the seed several times without succeeding. I have also embedded the seeds in green moss, and bound them with matting round the branches with no better results.

It seems to me that the Mistletoe is indigenous to certain localities. I am led to this conclusion from the fact that in the adjoining county, Somerset, it is plentiful almost to a nuisance, yet in this part of Devonshire I do not know of a single plant, and so great is the desire to obtain specimens that I am quite sure young Apple trees with the Mistletoe growing thereon would command a ready sale at good prices.—JAMES NICHOLLS, *Tunstock.*

ORNAMENTAL CONIFERS.

CYPRUSSUS FUNEBRIS (Funeral or Weeping Cypress).—*Nat. Ord.*, Pinaceæ, § Cupressæ. *Linn.*, Monocia Monadelphia.—A large evergreen coniferous tree, perfectly hardy, and extremely elegant in its growth. Mr. Fortune describes it as having a perfectly straight stem 60 feet in height, with branches growing at first horizontally, then taking a graceful curve upwards, the points drooping like a Weeping Willow. These weeping branches are long and slender, giving to the entire tree an extremely graceful weeping form. The branchlets are two-edged, much branched, Fern-like in appearance, covered with bright green adpressed leaves, closely imbricated, in four rows. This tree will be particularly valuable for "park scenery, lawns, the entrance to suburban villas; and an appropriate ornament to the resting-places of the dead." From Chinese Tartary. Introduced in 1849, by Mr. Fortune.

JUNIPERUS SPHERICA (Globe-fruited Juniper).—*Nat. Ord.*,

Pinaceæ, § Cupressæ.—An evergreen tree, said to grow from 30 feet to 50 feet in height. The branches are clothed with scale-like obtuse leaves, arranged in four rows, and having a

1. *Cupressus funebris.*

2. *Juniperus spherica.*

circular pit at the back; the young branches are usually very slender, and four-cornered from the regular disposition of the le ves. The fruit is quite spherical, glaucous, shortly pedunculate, and about half as large as the ball of a pocket pistol. From the north of China. Introduced by Mr. Fortune in 1850.

PIMELEA CULTURE.

The genus *Pimelea* is a small tribe of evergreen shrubs, all natives of New Holland. They may all by culture and training be grown and formed into beautiful specimens, both for ornamenting the greenhouse and conservatory and also for exhibition purposes. However, the two species most used for the latter purpose are *Pimelea Hendersonii*, with rose-coloured flowers; and *P. spectabilis*, which has a large compact head of white flowers. The last-named is the freest to grow, and, consequently, the hardiest species. Many a country gardener who runs up to London once a-year to see one of the great metropolitan shows would, no doubt, be glad to know how to grow similar specimens—such, for instance, as the annexed engraving represents. Those of our readers who may never have seen such a plant may rest assured that it is a faithful picture taken from a plant then living and flowering as freely as the engraving shows it. The name of it is *Pimelea spectabilis*.

Now, an ingenious thoughtful cultivator desirous of trying to grow a similar specimen, would first inquire, What soil does it require? Next, How and when am I pot it? Then, How shall I begin to train it so as to cause it to assume such a form? Then, as to watering, Does it require abundance constantly, or more at one time than another? Further, What heat does it require? and, lastly, Please tell me the summer general management and the winter treatment? All these reasonable queries I will endeavour to answer, and trust the treatment I shall describe will lead some of my younger brethren to try and persevere till they succeed. Many, if not all the great exhibitors, are self-taught men in the art of growing specimens. I have seen them at work in summer evenings till dusk training their young plants, making it their recreation and delight, spending their leisure hours in this innocent amusement. It was with them a labour of love, and so it must be with every grower attempting to grow specimens.

The first thing to be thought of is to procure the plants. I advise by all means to obtain young plants, and order them of a respectable nurseryman who has a good stock to choose from. Another point attend to—procure at least two plants, though three would not be too many. The reason for this, is one might fail. Have then, at least, two strings to your bow.

Soil.—The proper soil for a *Pimelea* is two parts fibry peat, procured from a dry moor where Heath grows plentifully (choose such, if possible, as is of a brown not black colour; if it is mixed with sharp white sand so much the better); one-part turfy loam from an upland pasture, which will require laying in a heap for a time to kill the grass or other weeds that might be in it. Add to these a regular mixture of charcoal or small pieces of sandstone, or even broken pots. These last are chiefly for the purpose of making the soil porous, so as to admit water readily to pervade the whole of the soil in the pot. If the compost is deficient in sand, add also a liberal mixture of what is called silver sand. At the time of potting mix all these well together. Pull in pieces the peat and the loam, but do not sift the compost excepting for young plants, and even for them use no finer a sieve than one with three-quarter-inch mesh. Then have ready a quantity of broken pots in three sizes, the largest to cover the bottom, the next to lay upon them, and the last next the compost. Pick out a few of the roughest pieces of the soil and lay them on the drainage. The pot is then ready for the plant, which

brings me to the operation of potting. Choose a pot at least one inch wider than the old one, and let it be quite clean.

Potting.—The best time for repotting is early spring, as a general rule—say from the middle of March to the beginning of April. Let the compost be moderately dry, and also the ball of soil in which the plant is growing. Turn the ball carefully out of the pot, and pick out nearly all of the old drainage, being careful not to bruise or break the roots. Should any be dead cut them away to a living part. Rub off some of the old soil, especially that on the surface. Then place some compost in the pot just sufficient to raise the ball level with the rim of the pot, fill in round the ball with the compost, pressing it down firm but not hard as it is put in. Fill up to the rim, and then give the pot a smart stroke or two on the bench, that will cause the soil just to sink low enough in the pot to hold sufficient water to wet the ball. Press the soil down again, level it, and leave it neatly finished. Then give a good watering and set the plant in its place not far from the glass. Young vigorous plants may very probably require a second shift about July; but the health and growth of the plants will be the guide as to this second shift the same year. If it has made great growth, then it will bear a second shift; but if it has not made great progress, then let it remain till spring comes round again. Large plants will require a larger shift in proportion. A plant growing in a six-

inch pot should be potted into one eight-inches diameter, and one in an eight-inch pot into an eleven-inch pot.

Training.—If the plant has only one straight shoot, rip off the top 5 inches from the soil for the purpose of giving it a short stem about 4 inches high, clean of branches. Such a dwarf standard is preferable to one with shoots close to the soil.

This stopping should be done shortly after the plant has been potted, then replace the plant or plants in the greenhouse as near the glass as may be convenient. Three or four shoots will break forth near the top of the shoot. These must be allowed to grow the first summer without stopping, only

when they have attained 2 inches or 3 inches in length place as many neat small sticks painted green as there are shoots at equal distances all round the plant. Then tie each shoot to its nearest stick, but be very careful in the drawing the shoots to the sticks or they will split off at the base just where they spring from the centre stem. If any of the shoots are stronger than the rest, let such be more bent down to check the strong growth; and, on the contrary, keep the weaker shoots more upright, which will give them more strength. The point to be aimed at is to have these shoots well balanced and of as equal strength as possible. They form the framework or main branches of the future plant.

The spring following, after repotting, these first shoots should be stopped, or, rather I should say, cut back to 3 inches in length from the main stem. They may be allowed to send out three shoots each, and to each of these a small stick should be placed, and the shoots tied to them so as to form a round head in the form indicated by the above woodcut. Replace the plant on the greenhouse-stage, and expose every part of the plant to an equal share of light. This is of great importance. If the cultivator has a span-roofed greenhouse that will be easily managed; but if the house is a lean-to, then he must turn his plant very frequently, or the shoots at the sides furthest from

Pimelea spectabilis.

the light will be weak and drawn, and the consequence will be a one-sided plant. Attending to this point and keeping the plant properly attended to with water, air, &c., it will form a handsome fair-sized plant the second year. The following spring repeat the operation of repotting, stopping, and training; though if the plant is strong and healthy it may be allowed to flower moderately, and as the flowers are at the ends of the shoots they will be stopped naturally. Care must be taken that the shoots year by year are carefully thinned, so as to give air and space for the leaves to expand.

Watering.—Use soft water always. Rain water is the best. Give most water when the plant is growing freely—that is, during the spring and summer, through autumn and winter only give just sufficient to keep the plant from flagging. Keep a temperature up in winter of from 40° to 45°, and in spring it may be increased to from 50° to 55° in-doors.

SUMMER TREATMENT.

Young specimens should be removed out of the greenhouse in May, and put into a cold pit well glazed. Cover the bottom with dry coal ashes, and set the plants upon saucers turned upside down, or on bricks just so high as to allow head-room for the plants without touching the glass. Every fine day draw the lights clean off, and expose the plants to the full air. See that they have plenty of room. At least there should a foot space from plant to plant. Nothing injures specimens more than over-crowding even in the open air. In this pit they should remain all the summer, give them abundance of air every day and night too in warm weather. In heavy rains, if they are kept in a pit, they can be sheltered from excessive wet, and yet have air given them to keep them cool. During bright sunshine shade them with canvass or netting. When they have attained a sufficient size and strength then they may be set out in a sheltered place, but not near a wall, hedge, or tall trees. As soon as the nights begin to be cool, approaching frost, remove them into the greenhouse, first examining the pots, and if they are dirty let them be thoroughly scrubbed clean. Of course, during the entire season no weeds must be allowed to grow in the pots, nor yet any moss on the surface, and the plants will be benefited if the surface of the soil in the pots is frequently stirred, and even a little fresh compost added when the plants are housed for the winter.

WINTER MANAGEMENT.

This treatment may be described in a few words. Keep the air in the house sweet, and renew it by opening the lights every fine day. In damp foggy weather light the fires in the morning, and give air to dry the plants. Give but just water enough to wet the soil, and invariably supply that liquid in the morning. Allow no dead leaves or other decaying matter to remain in the houses. In frosty weather, of course, secure sufficient heat to keep it from the plants. By attending carefully to these directions, and destroying all insects that may attack the plants, an assiduous cultivator may grow a specimen equal to the engraving.

T. APPLEBY.

TRADE LISTS RECEIVED.

Descriptive Catalogue of Select Vegetable and Flower Seeds, by William Drummond & Sons, Stirling, N.B., and Dublin.—This is a very good and useful catalogue. Accompanying it are two small pamphlets—one containing "Directions for Sowing and Cultivating Vegetable Seeds," and the other "Directions for the Culture of Flower Seeds." Both of these are well written, contain good practical information, and will be found useful monitors to the uninitiated.

James Hunter & Co.'s Spring Catalogue and Price Current of Seeds, &c., Bristol, is an ordinary seed catalogue.

WORK FOR THE WEEK.

KITCHEN GARDEN.

In the open ground seeds of vegetables should be got in as expeditiously as possible. At the same time, should the weather continue wet, it will not do to trample the ground too much. In such a case, many crops may be sown in heat, to be transplanted at a more favourable opportunity. *Asparagus*, give plenty of air to these and all other crops in frames. *Cauliflower*, plant out from the seed-pans all the young plants before they become too much crowded, and, if needful, make fresh

sowings. Dung and dig a piece of ground for planting out the plants from the pots in which they have been wintered, or from the frames, to be covered with hand-glasses, placing a strong plant in each angle; to be well soaked with water before they are turned out. *Cucumbers*, sow seed. *Carrots*, sow in frames, and thin those already up; also sow a crop in the open ground. *Dwarf Kidney Beans*, pot off all that are fit as soon as possible, and sow fresh crops. *Horseradish*, plant, if not done. *Lettuce*, sow a crop of Cos in frames, and in the open ground. *Potatoes*, plant on a warm border. *Sweet Basil*, sow in heat, as also Sweet Marjoram and Tomatoes, Sea-kale and Rhubarb, for next year's forcing to be planted on deeply-trenched and well-matured ground; a hillock of straw or light litter to be placed over the crowns to protect them from the vicissitudes of the weather.

FLOWER GARDEN.

Let all ornamental planting be finished betimes, and protect those planted in autumn from wind-waving. Pot Moss and Provence Roses and Persian Lilacs for future forcing; plunge them immediately, and mulch them over. See to the sowing of tender annuals in heat; and a few of the Californian and the hardier sorts of annuals may be sown in the borders. *Ranunculus* to be planted as soon as the frost is out of the ground, and the surface in a fit state to rake; to be planted an inch and a half deep.

FRUIT GARDEN.

Prune Raspberries. Any Gooseberries and Currants not previously pruned should forthwith be attended to.

STOVE.

Any specimen plants in the house which require shifting should be attended to in the course of the month. Give *Stephanotis floribunda*, and *Alamanda cathartica* and *A. grandiflora* a brisk bottom heat. Pot *Gloriosa superba*, and begin to start some of the best of the *Gloxinia*, *Gesneria*, &c. Cut back some of the kinds after flowering to form bushy specimens, and to increase the stock by cuttings.

GREENHOUSE AND CONSERVATORY.

Persuvere steadily in the directions as regards temperature, &c., laid down in previous calendars. A slight advance in heat may be made on bright days; but if cloudy skies intervene, revert immediately to decreased temperature and less humidity. The young plants of *Fuchsias* may now be shifted into large-sized pots. A general compost to grow them in is one part turfy loam, one part leaf mould, one part peat-earth. To this mixture it is requisite to add a small portion of sand, to be well mixed previous to using. The *Camelias* done flowering to be removed to a moist atmosphere, and a temperature ranging from 60° to 65°. Climbers to be pruned, cutting away weak and decayed wood, and shortening back shoots to provide bottom wood for the ensuing season. As the natives of various climates are kept together in a greenhouse, it is advisable that some arrangement should be as far as possible that the plants of warm climates may be accommodated with the warmest place, and that others of more temperate climes may be supplied with a free circulation of air.

FORCING-PIT.

Keep up the temperature to 65°, so as to be able to give air freely day and night in favourable weather. Fumigate to keep down green fly, and syringe lightly every afternoon between two and three o'clock.

PITS AND FRAMES.

It is now time to commence in earnest the propagation of all softwooded and free-growing plants for the adornment of the beds and borders in summer, and for that purpose a common dung-bed frame, having a slight bottom heat, will suffice. Fill up to within 1 foot of the glass, upon which place about 4 inches of dry sandy soil, in which the cuttings may be put directly you can procure a young growth for the purpose. Some prefer to put the cuttings in well-drained pots of sandy soil, and to plunge the pot to their rims in the dung, and others advise to strike *Verbenas*, *Fuchsias*, &c., in pans of wet sand, which is an excellent plan later in the season; but during the present dull season they would be liable to damp off. Alpine and other rare plants in pots to be looked over, removing all decayed matter, and stirring up the surface of the soil. Those which it may be desirable to propagate should be divided into pieces, repotted, and placed again in the frame. Sow seed of *Salvia patens*, as they make better flowering plants raised in this way than by cuttings. Commence top-dressing *Auricularas* as early as convenient. Pro-

pagate *Dahlia*s of which a good stock is required, by putting them in heat till they break, and then removing the young shoots, each of which to be potted in a small 60 or thoub-pot, and placed on a hotbed which has stood long enough for the moist heat to pass off, which would be fatal to the young plants. The frame to be kept as close as possible, and water to be given frequently; but a careful watch to be kept to prevent the access of hot steam. Sow Mignonette, Sweet Peas, Ten-week Stocks, &c., in a gentle bottom heat. Prepare soils by getting them into sheds to dry and sweeten for spring use. W. KEANE.

DOINGS OF THE LAST WEEK.

This has chiefly been confined to works of routine. The frost that came again on Sunday has prevented us going on with Box-edging and gravelling, but furnished a good opportunity for turning over the ridges in the kitchen and flower gardens.

BOX-EDGING.

Many mistakes and extra labour are often incurred with Box-edging, by trusting entirely to the eye and the line for the level, and there is shaving off here, and adding there, and yet no certainty that all is right. The inclination of a long walk is also very deceiving. I have had people betting that they were sure that the walk fell from them to a certain point, whilst from that point to where they stood the ground actually rose 3 feet or 4 feet! In such cases, the walk will look best if at all straight, if the decline is regular so much in every 10 feet or 20 feet. The two sides on ground at all level, should also be level with each other. The first thing to do, therefore, is to secure the desired level on one side, by means of stakes put into the ground, and a stout line placed over them so as to secure a uniform sweep, which nothing tells better than a tight line and a gardener's eye. Place in similar stakes on the opposite side of the walk, and exactly on the same level, and then it is next to impossible to go wrong. Then the soil must be made up to that level, forking over the bottom and trampling it hard, adding the most of what is wanted at two or three times, and securing a width next the walk fully 3 inches or 4 inches beyond the line. When the soil is about the height of the line, beat it down firmly with a rammer, and make any inequalities all right with some fine soil on the surface, and beat firm with the back of the spade, and then cut out with the spade close to the line for the Box, which plant with the finest soil squeezed firmly against it. In winter a little sand should also be trickled along the line of the Box, which fills up all crevices, and if some is left on the Box it will help to protect it until the frosts are over. All the soil left after planting on the walk side should be cleared out after planting, and in winter and early spring especially some fine gravel should be placed against the Box to prevent the frost breaking the line. I know that Box is often planted with a title of the trouble mentioned above; but then there is the risk that the edging will sink in one place and be left standing high in others. As such jobs are rather permanent, it suits best to make the ground uniform in firmness, so that there shall be no sinking at all afterwards. If old Box is to be used, it ought to be earthed-up a twelvemonth beforehand, so that there may be plenty of roots near the top, as it is best to use rooted slips some 6 inches or so in length. The top of the Box should also be pruned level, so that when left an inch or so above the soil, it may all be level to the eye from end to end. In cold, stiff, clay soils, a little sand and fine leaf mould against the roots of the Box will benefit it much and give it a good start.

WALKS.

In new walks it is as well to do what draining is necessary as soon as the Box is fixed; and in gravelling, if at all rough, the dryness of the walk will much depend on the roughest gravel and stones being placed at the bottom. In such cases, walks will not only be generally dry, but even when on a slope they will be little liable to have the surface disturbed and run even by the heaviest rains.

Another thing to be guarded against is the rounding of walks too much. We should not like to have the centre higher than the outside—say for a six-feet walk $1\frac{1}{2}$ inch, and for a twelve-feet walk from 2 inches to 3 inches. In a celebrated public garden, we noticed a walk once made by a great authority, which must have been some 12 inches or 15 inches higher in the middle than at the sides where it joined the lawn. We

never stepped upon a more uncomfortable affair. We have heard of those not very bright, being initiated into knowing their left from their right leg, by one being bandaged with a hand and the other with a strawband, whilst the teacher put them through their facings by shouting out, "May leg, straw leg," and no one could walk on that wide walk without mentally saying to himself, "High leg, low leg, long leg, short leg." The more level walks are, the easier will they be to walk on.

One word more to amateurs. If the bottom of their walks, and also the rough stones at the bottom, are well covered with coal tur, or the gas lime from gas-houses, it will be long before worms, or even many weeds disturb them. Nothing takes more from the beauty of walks than worm-heaps, and whoever in a small place is near to a gas-house may, in the forming of their walks, pretty well set them at defiance.

ROUTINE.

Dried horse-droppings in a shed for Mushroom-beds. Earthed-up Potatoes in pots. Sowed some Celery and a few flower-seeds, being afraid to sow such things as Capsicums, Basil, and flower-seeds, as we know not yet where to put them when growing. In a month, by turning out many things into temporary beds there will be more room, and nothing is gained by early sowing unless things can be kept growing on. Celery is one of those plants that may be sown before Christmas and not bolt the sooner, if you can keep it without being checked; but if you sow in March and allow it to get checked, you may have all your crop bolted. It is the treatment, the kind growth, and not the mere time of sowing, that will secure good unbolted early Celery. The incomparable, a dwarf white sort, but which is eatable for nearly the whole length, is very hardy, and may be grown thickly in beds, I begin to use in preference to every other sort, more especially as those who are judges begin to notice its fine qualities at table before they knew it was a particular variety. We have not had a single bad or run head of it this season. The earthing-up is almost a sure cure, as you may send plants to table 9 inches or 12 inches in length. When undressed they may be about 13 inches or 14 inches.

FRUIT GARDEN.

Much the same as last week; and have begun to put in a few cuttings of *Verbena*s that are at all scarce. My stores always stand in the cutting-pots all the winter. They will be set in a bed of leaves, with a fair heat and a frame over them, and some 15 inches or 18 inches from the glass, so as not to require much shading. The smallest bits are now used—two buds, or even one bud, with a good piece of the stalk, for the stalk between the joints will root fast enough. I was pretty well knocked in a heap by seeing at the first commencement as much thrown down as waste as some clever fellow would make a fortune of in the case of a new sort. After storing in little room all the winter there ought to be no waste now, and nobody but a particular friend should expect a handful of cuttings now, though there might have been truckloads in summer and autumn. If you ask me if this bed of leaves (tree), is the best thing and place for these cuttings, I say No. I would have preferred a propagating-house with bottom and top heat from hot water, and the ability to use the syringe in a bright day instead of shading. But we must make the most of what we have; and have tried to avoid one danger from the tree leaves—that of small slugs raked up with them, by turning and watering the surface with boiling water, a large water-pail to each light, then turning some quicklime among them, and then covering with dry coal ashes. These little matters often make all the difference between success and next-to-failure. We have some Ferns looking sickly from potting them in winter in cold instead of well-aired and heated soil. We have known fine collections of Melons sown in an afternoon, and not a seed left in the morning, from the pots not being protected from mice.—R. F.

TO CORRESPONDENTS.

** We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the "Journal of Horticulture, &c."* 162, Fleet Street, London, E.C.

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

We cannot reply privately to any communication unless under very special circumstances.

GARDENERS' BOOK-KEEPING (H. J.).—In London's "Self-Instruction for Young Gardeners," published by Messrs. Longman, you will find the information you seek.

TIERS LABELS (H. R.).—We think a copy of the horticultural tool makers who advertise in our columns could supply you.

FLOWER-POTS—DIVISION (Young Photo).—A cast of pots is a trade term, and always signifies of a certain number according to size. These casts generally sell for the same money down to 16's; above that you pay more. For instance, a cast of 60's, large or small will give you sixty pots from 25 inches to 45 inches; a cast of 32's will be thirty-two pots of 25 inches and so on; a cast of 16's will be twelve pots about 10 inches; and these will be about half as much more as all the smaller sizes below them, and larger sizes will be two-and-a-half times as much. For instance for four pots 15 inches each, you will pay about as much as for 150 60-sized pots. We do not consider the number of holes necessary; but if you like them best, the very best from a horticultural point of view, is a pot with the sides gently with a bar or hammer. A glass partition would be far the best. There would be no necessity for raising the borders so high, unless you deemed it necessary. We have no objections to the plans of heating you propose; but as the fire is there we would first see what could be done with it before removing it. The back border might be separated from the front by a few inches and made the same height. The division would give different temperatures, and the amount of air would do more. The top of the flue might also do for many purposes where extra heat was wanted. Why not, therefore, try what you could do with the flue, by making the bars work 18 inches, putting in a block so as to narrow the neck of the flue, and place a damper to regulate the draught? We fear if this you cannot make, we will think your purpose, you will also have trouble with the stove.

ROYAL BOTANICAL SOCIETY (Subscriber).—We do not know anything about the arrangements of the Royal Botanic Society. You had better write to the Secretary.

WALL-FRUIT GLASS STRUCTURE (Subscriber).—If you take any one of the opinions or practices referred to by you and carry it out, without mixing one with the other, you will not be far wrong, for after all the best is that which is carried out best. Your raising the wall will be well enough; but for ourselves, we have the legality of moving anything that has been thoroughly fixed into a wall, or founded in the ground, then a written agreement with the landholder; but that is a lawyer's question, and a tenant's rights and landlord's rights we do not pretend to understand. For the sashes might rest at the top under the coping, or in the ground, and a board from 12 inch to 2 inches thick and 5 inches wide, might be better, with stout nails under the coping, and if a bolt with your neighbour's permission passes through the wall, and was screwed on the other side, with a piece of wire 4 inches long, and the nut, the wall would be as rendered all the more secure, and you could screw the sashes to it; but that board, however, you would have to leave. The front you could raise to what height you liked and without posts, by fixing a sole plate to the blocks of the coping, and these blocks might have posts driven in the ground in front of them, to keep them steady, which posts might be left for the benefit of any one; but for these tenets matter in the cheapest, and we think the best, would be a fixed roof, and just take things as they are. Fix the board under the plate as proposed, set 3 feet or 4 feet above the ground, and on that place a wall-plate, fasten rafters 25 inches deep and 12 inch wide, by the top to the eaves-board, and at the front to the wall-plate, placing them all so as to receive glass 18 inches or 20 inches wide, by 12 inch deep. Leave a space all along the top for a foot ventilator, or have a ventilator the depth of two squares, hung on pivots between every alternate rafter, that is allowing one line of glass to go to the top, and the next line to be broken by a ventilator. Then for the front have a line of glass next the plate, one of them 12 inches deep as described at page 322, Vol. XXV. For glazing might be fixed with sashes, or hinged to open downwards. For moving, the moving, however, sashes would be best, though more expensive.

BEST TWELVE PANSIES (Anateur, Blackpool).—*Sells*.—Maid of Bath (Hooper), white; Rev. H. Donbram Downie & Laird, dark; Yellow Yellow Grounds—Francis Low (Downie & Laird), extra fine; Sir J. Cathcart (Turner), shy grower; General Young (Pollock), Mrs. Downie (Downie & Laird), deep gold. *White Grounds*.—Lady Lucy Dundas, extra fine; Mrs. Laird (Downie & Laird); Countess of Rosslyn (Laird), good; Joseph (Dickson & Co.), fine. Perhaps our "Florist's Flowers for the Many" will suit you. For five penny postage stamps you can have it free by post from our office.

VARIOUS (Datal).—Train the trees to wire an inch from the wall. China Asters will bloom late in pots, provided you sow the seeds about the beginning of June, and protect from rains and frosts in autumn. Nothing answers a digging you will see stated in our last Number.

GRAFTING (J. Q.).—You can have a free by post five penny postage stamps "Fruit Grafting for the Many." If you send them with our office with your direction. There are full directions and woodcuts which will give you more information than we can find room for in this column.

FRUITS OF GARDENERS' HOUSE (Live and Let Live).—We can scarcely imagine a case when the gardener living in a house on his employer's estate could be liable to reprove himself. The usual terms of hiring a live in. The house is, therefore, a part of the wages; if there were no house more money would have to be paid to the gardener.

YOUNG WOOD OF PLAIN TREES (H. J.).—Although not fully ripened, yet, we think, the wood sufficiently matured to be pro-native. We should prune them rather shorter than usual, and use protection from spring frosts and nights.

PLANTING A GARDEN PLAN (H. C.).—We never undertake either to suggest alterations of ground plans, or to recommend the arrangement of colours, &c. All that we can do is to point out ourselves to ourselves, and to others, is to point out what we consider errors in plans sent to us, on which are stated the plants proposed to be employed and their intended arrangement. We can criticise, but we cannot plan or plant unless named.

INSECT ON DEAD FERULIA ROOTS (An Amateur Gardener).—We think the same kind of Acorns, that lives on dead vegetable matter; but we cannot say what it is from your description. We suspect that such insects may do harm and can do no good to living plants; secondly, it is doubtful if Gi-hurst Compound will kill them underground, and if it did would be apt to render the soil unwholesome; thirdly, the Compound if used on the surface plants above ground, it must be very weak or it will do so, and we should never think of using it at all above the surface; and fourthly, whether it would kill them or not, as it would do away with the sweetness and natural character of the soil, the best plan you can follow to secure freedom from all such insects, worms, &c., in your soil, is the right way. You over-water, and then you water, and moisture before using, or plance the soil in boiling water, pour out when it begins to cool, and then dry air the soil in it if it is neither wet nor dry before using. Fresh soil will often have such insects and worms unless so treated, and it is easy to half-churn, or soak as many turves as would grow many plants, and on such means we would have more faith than doing with Ghurst Compound.

GROWING SPECIMEN FERULIAS (J. L. S. M.).—The good turfy loam, with a little very rotten dung for Fuschias, and they will be better of all sorts of manure watering if given clear and weak enough. One ounce of guano won't do the same as two of any other manure. It is better to use the same. A peck of sheep-dung would make a half-hundredweight of manure strong, and so on of other manures. Judicious treatment is not to use it rank nor too strong, and to vary the kinds.

ORCHIDS IN A GREENHOUSE (Orchideeum).—Your attempt or trial for growing orchids in your greenhouse will be successful, provided you set to work in the right way. You have your plants in a Skirven with only one stem. The skin, as you term it, that arises before the plant, and the remains of the spathe leaf that wrapped up the embryo leaves last season; care not for its turning brown, it should do so. You potted it in rough peat and charcoal, and have kept it damp, not wet. This treatment at this season of the year is wrong, it ought to have been kept dry for two or three months; the damp has caused the roots to turn mouldy. You have done right to keep the *Dendrobium densiflorum* quite dry; keep it so till the growing season (May) arrives. The *Odontoglossum grande* you may water in the right way, if it dries up, it would have been better had you delayed purchasing these. Orchids till spring, and then water them as you had them from has grown them in an ordinary Orchid-house, and, in consequence, they will be rather tender to be placed at this time of the year in a greenhouse. As a dividend before you must keep them dry, and besides that care will be a good watering in your greenhouse, shaded from draughts of cold air. Should they even seem to shrivel up a little do not be alarmed; when warmer days come and they begin to grow they will soon get plump again. It will be advisable whilst they are in this state of rest to keep them in a warm bright sunshine with an old newspaper or thin tissue paper; keep it arched over the plants, and when you observe the buds at the base of the pseudobulbs begin to grow, then give a little warm water to them out of a small spout. Let this first water be given round the pot-edge, just within the rim, never mind the centre being dry. In a fortnight or a month you may begin to water them in the same way, and when the surface becomes dry repeat the watering. As the young plants increase, you will see young roots pushing out from its base. By that time the heat of the season will have increased so much that you may venture to water all over the compost, only take care not to wet the young rising shoots. Keep them in the greenhouse all the summer, and perhaps you may be able to perfect the first shoots; when that is achieved, then without watering entirely through the winter as before. As the plants are so small, we must advise you to be very patient and persevere in careful culture till the plants have made several successive yearly growths. This they must do before you can have flowers. Spaghnum is common in the earth, but it will grow plentiful enough on wet boggy mosses. It is whitish-green when growing, and dies quite white; no other moss does so, therefore, you cannot mistake it. You might obtain the small quantity you will need for several years, from any of our nurserymen that grows Orchids.

JASMINE MULTIFLORUM AND ARISTOLOCHIA SIMPLA (Laural).—Both these flowers, like all climbing plants, will not flourish unless well supported, require the very best borders that can be made, and where Peach and Nut-tine trees would flourish would be the sort for climbers. We wish that we could enlist the spirit of the age in gardening to a more thorough knowledge of the requirements of all manner of climbers. Many climbers, and more especially the particularly climbing roses, are liable to be killed by frost, and we prefer plants which are not in the best condition; and nothing can be more nasty about doors and windows than plants infested by insects. All good climbers in all good borders and aspects would apply by a weekly watering of the stems with a solution of sulphate of iron to the roots; and if anything good (manure) was at hand to add to the goodness of the water, so much the better. Under such conditions there is not a pin's difference to choose between *Aristolochia simpliciflora* and *Jasminum multiflorum*, only that the first is the stronger in the second for winter. Spigo when done well has the most magnificent foliage of all hardy plants, and it is to its leaves only that it is ever planted. In good, rich, holding soil it never takes the fly or any sort of insect, and never has a hot-looking leaf; but on poor hungry soil and in slovenly hands there is not a greater scarerow in all the climbers. The best time for sowing is the second for winter. Spigo when done well has the most magnificent foliage of all hardy plants, and it is to its leaves only that it is ever planted. POULTRY, BEE, and HOUSEHOLD CHRONICLE.

POULTRY, &c., SHOWS.

MARCH 1st. HALIFAX. *Sec.*, Mr. J. W. Thompson, Southwam, near Halifax. Entries close February 20th.

MAY 14th and 15th. TAUNTON AND SOMERSET. *Sec.*, Charles Balfance, Esq., Taunton.

MAY 27th, 28th and 29th. BATH AND WEST OF ENGLAND (City of Wells). *Steward*, S. Pitman, Esq., Manor House, Taunton. Entries close May 1.

JUNE 4th and 5th. BENTLEY AND EAST RIDING. *Sec.*, Mr. Harry Adams.

CHRISTMAS POULTRY MARKET.

(Continued from page 384.)

WE may, perhaps, be excused a small digression while on the question of buyers, when we speak of a class not only met with at Christmas but at other times. We knew of a banker (deceased only within the last few years), one of the most aristocratic of his class, and one of the most eminent; who, although he would in his private room in Lombard Street, or on Change, estimate his time by seconds, yet at a second-rate shop in Leadenhall would spend a quarter of an hour over the outlay of a few shillings in purchasing of the most inferior quality that which he could have ordered at a respectable shop, and have had of undeniable excellence for, perhaps, eighteenth-century more. With many people it is the work of a lifetime to convince them they can only get money's worth for their money. They believe in their ability to get pictures, furniture, fish, poultry, and so on, at less than its value. They buy nothing; they "pick up" everything. We believe it is seldom that the retail buyer is as good a judge of an article as the man of whom he is buying it; and if he is, he gets only fair exchange.

We need hardly say after the description we have given, that Christmas is a time of very severe labour both to masters and men. It is followed by a rest when the market has been a good one, and all has been sold; but sometimes the supply has exceeded the demand, and the consequence is a heavy stock, for which there is no sale, except a forced one.

For a week after Christmas little lots of goods, generally the most expensive, are brought back by those whose anticipations have been too grand. Those who are not acquainted with these trades would hardly believe the adverse influence of a wet day. People are wanderers on Christmas-eve. They are also rather more money to spend at that time; and the man who is a small and close buyer for a coarse article at periods during the year, will not sacrifice his annual importance by going to a shop where his deviation will be known, and, perhaps, remarked upon. He will go where he has never been before; will ask the price of his treat as though he bought such constantly, and will coolly consult his wife or his friend whether they think the article so good and as large as that he bought a day or two before. This can only be done at a distance from home.

It is not confined to eatables, the same man practises it in wine. He buys two half-dozen at Christmas. He walks in to a small wine-merchant's some distance from home, asks how sherris are, and when told there is a "nice thing at forty," buys half a dozen as a sample.

If these same things are done in their own neighbourhood, they rather diminish than add to their importance. "Scroggins is coming out," says the butcher's boy going home with the beef. "Wish it may last," says the barman of the neighbouring wine-vaults, as he delivers the "three of red and three of white." A wet evening compels all these people to buy at home—that is, in their own neighbourhood, and as we have said, they are not then as good customers as they would have been elsewhere; hence after a wet day or two lots of expensive poultry come back to market, and the row of enormous Turkeys that was admired at Leadenhall a week before, and formed the pride and attraction of a shop for five or six days before Christmas-day, are reconsigned to a salesman, like pointers in February, hunters in May, and traps and belongings, the property of an officer ordered to join his regiment in India, "to be sold for what they will fetch." The pleasures of hope and of memory may be well in poetry, but ask the owner of these poor birds what he thinks of them. When he bought them his mind showed him long before he got home the exact place where he would hang them. On his way home he asked himself if he had not bought them dear; when he unpacked them he decided that he had not; and he called the attention of all his customers to the row.

It was with him as it often is with many. His goods were more appreciated and admired by himself than by any one else. One said they were nasty, great, coarse birds; another preferred a delicate hen; and a third thought it wicked to give such a price for anything eatable. The buyer thought the first day they would make their money at any time; the second, he doubted whether they would pay much; the third, he tried to sell them at cost price; the fourth, he wished he had never seen them; the fifth, he wished somebody would steal them; and two days afterwards he took them back. Given in this case to find the pleasure of hope and memory. These are not the only goods in the market; but they are all of the same date. Many small packages that arrive during the busy week are unnoticed; others fall down between or behind the large hampers; some few are lost altogether. But for these waifs and strays there would be nothing for sale for some days. Country people, like Londoners, are keeping Christmas. Little by little these remnants find buyers. It is Hobson's choice with those who want. They are the last signs of Christmas; the excitement is past, and things subside into their accustomed track.

THE CHINCHILLA OR SILVER GREY RABBIT.

THIS has for some years past taken a place amongst the fancy Rabbits of this country, to which it is well entitled from the great beauty of its colour. It derives the term Chinchilla from its similarity in colour to the animal of that name, which is so famous for its rare and valuable fur. The Chinchilla Rabbit was imported into this country about seven or eight years ago from Belgium, into which country it had been introduced from France. Those in the Zoological Gardens, Regent's Park, were brought there from the Zoological Gardens at Antwerp, and afterwards crossed with some bred from the wild Silver Grey by the writer of this paper. The dark wild Silver Grey Rabbits for centuries have been bred in warrens in Lincolnshire for the sake of their skins, which are exported in large quantities to Russia and China, where they are made up into dresses in imitation of the silver grey fox, and also the sea otter, the skins of which vary in price from £20 to £50 each, according to their quality. It is not known when the wild Silver Grey was first brought into England. Within the last twenty years some have been brought from the Lincolnshire warrens and introduced into warrens in Norfolk, Suffolk, and Wales, and there is also a small warren of them in Sussex. One warren in Suffolk, between Brandon and Thetford, comprises 3500 acres of barren land, from which 35,000 Rabbits are annually killed. They are not so hardy as the common Grey wild Rabbit, and require feeding through the winter. The value of their skins is from £1 to £1 4s. per dozen.—HUNTS.

A RARE OCCURRENCE.—Mr. Robson, gamekeeper to Colonel Leslie, Tetternear House, had a Silver-spangled Hamburg hen built a nest in a tree. Its poultry were in the habit of roosting in some apruces close to his house. The usual process was gone through, first of carrying sticks, then straw; but when about finished it was by accident destroyed.

THE CANARY AND THE BRITISH FINCHES.

(Continued from page 366.)

PAIRING AND BREEDING.

It is generally recommended in pairing Canaries for breeding purposes to match a Jonque or Yellow cock with a Mealy or Buff hen, and *vice versa*; it being thought that if two Jonque birds are paired together, that the young ones produced from such coupling are more delicate and rotten-feathered—that is, the plumage is rough and disordered, and the feathers are apt to fall out, so that the bird has a ragged and muffled appearance.

There may be some truth in this theory when the birds which are paired together are nearly related or already of a degenerate and weakly stock, but it is not borne out by my experience where the birds are hearty and not too closely allied. I consider the coupling of a Jonque cock with a Jonque hen (I am speaking of clear or whole-coloured birds) produces the highest-coloured young; but I should not think of pairing birds more nearly related than cousins if I could avoid it.

In breeding Pies, for accuracy of marking it is advisable to have the parents as nearly correct in their division of colour as possible; and if one is rather deficient in one mark the other should have it in greater proportion, in order that the property may be more evenly balanced in the progeny. Undoubtedly there is much truth in the saying that "like produces like," and, therefore, it is advisable to have the parents as correct as can be obtained; and the greater number of generations back that their parents have been bred to that particular variety, in the same ratio may the young be expected to come true.

It must, however, be remembered that the original colour of the Canary is a dark greenish-grey, and that consequently there is always a tendency among strong, hearty birds to return to that colour; therefore, in breeding accurate Pies, it would not be better to match two birds together for breeding which were already too dark, as the young would, in all probability, be darker still.

The same remark holds good of breeding the London Fancy Canaries. If two dark or strong-coloured birds are coupled the young would be still deeper in colour, and in a few generations would return almost to the Lizard variety.

It is on this account that the breeders of London Fancy birds recommend that if one is too strong in colour it should be mated to a soft or pale-coloured bird, in order to counteract the natural tendency. It may not be out of place to remind the amateur that in-and-in breeding—that is, the pairing of near relations together, not only makes the offspring more delicate, and, consequently, less able to withstand an attack of disease, but also softens or lightens the colour, and it is not improbable that many of the light-coloured varieties of Canaries may have sprung from this cause or albinism.

In selecting birds to breed from I should prefer a two-year-old cock, and both should be lively and well. March is a good month to pair them; but if you have convenience to keep them from severe cold they may often be paired earlier with success.

It is best to put the cock in the breeding cage first, and let him get acquainted with his new abode, so that he may be master of his future house. He may receive a small quantity of hempseed to excite him, and when the hen is turned in, commence at once to feed with bread, egg, and mawseed in the side-pan, or some such nutritious food as you desire them to rear their young on. When two hens are to be put in one cage, to one cock, it is better that they should have been previously acquainted by having been kept in the same cage; this may prevent after-quarrels.

In a room or aviary one cock is sufficient for four hens; and it is better not to have two cocks unless it is large.

When the hen is about to lay, which may be judged by her appearance and the advanced state of her nest, it is well to mix a little moist sugar in their soft food, which, acting as a gentle purgative, may assist the hen in laying and prevent her being egg-bound—a complaint that kills many young hens in cold weather. A piece of cuttlefish bone, or mortar with a little salt in it, is also useful at this time for the birds to peck; and I chop up the shell along with the hard-boiled egg.

Plenty of green food, as chickweed and groundsel, are much relished by the birds, and they feed their young largely on it; but it should be fresh, as stale green meat is thought to be injurious.

The hen Canary usually lays from four to seven eggs on some successive days, and incubates thirteen or fourteen days. Some fanciers remove the eggs as laid, substituting a bone or ivory egg till all are laid, keeping the eggs in a cool and safe place, and returning them when the hen ceases to lay. This is very necessary if the cock is inclined to be mischievous, in which case he should be removed, or placed in the compartment of the cage when the eggs are put into the nest. It has also the advantage of hatching all the young at one time, so that they obtain an equal share of food, for it must be remembered that the birds are in an artificial state; and though it is always best to leave them to their own instincts as much as possible, yet their being confined so close to their nest, they visit it oftener than they would do if flying at liberty and having to search for their food. Thus it is that the cock will sometimes be too officious and meddling, and his fondness for eggs may take an unnatural turn, or the hen may be induced to sit before she has finished laying—irregularities that would not be likely to occur in a state of nature. The advisability of careful watchfulness is therefore apparent, and the fancier must use his own judgment in each case, remembering that if all goes on properly, the

less he interrupts them the greater will be the chance of his success.

When the young are expected, let the old birds have a plentiful supply of soft food and green meat once, at least, or better, twice a-day. If given overnight they can get it early in the morning. There is rarely much trouble about the hen feeding her young ones; but I have had cases in which the hens have sat close on the young and starved them to death, never pretending to feed them, and I am unable to offer any advice when the natural instinct fails; but I consider it of rare occurrence, and only happens to such birds as have, perhaps, sat on unproductive eggs a season or two, and never had any young ones to feed. These birds are often excellent incubators. I do not call to mind that I ever had a young hen refuse to feed her nestlings; all I can advise if the hen does not feed the young, which may be seen by examining their throats if they contain any food or not, is to drive her off the nest two or three times a-day, or oftener, that she may feast on the good things provided, and when she returns be tempted to feed by seeing the little gaping mouths in her nest and hearing their faint cries. If once she begins to feed she will generally continue.

A young cock may sometimes be too affectionate, and even eat the beak which he ought to fill; but a cock that has once reared young ones, will frequently feed all those that cry to him, though there is much difference in the dispositions of different birds.

When the young leave the nest, and the hen commences building again, she should be watched, if in a cage, that she does not pick them to line her new nest; for as she has no reason to understand that it hurts them, her instinct only prompting her to carry any soft substance to her nest, consequently, if they are not placed in the compartment so that they can be fed through the wires, they may be much disfigured. Where they have plenty of room but little danger exists.—B. P. BEENT.

CHEAP SUGAR FOR FEEDING BEES.

FEEDING bees last summer I sent for some crushed white lump sugar, but found my grocer had sent me some of the enclosed at 5d. per lb. As I live some miles from the town I was obliged to use it, and find it a very pure sugar—if anything, purer than leaf sugar. I fed my bees last winter entirely on it, and find it makes a very fine and clear syrup.—A. W.

[The sugar which accompanied this letter is a very good sample of what is known in the trade as "crushed lump." Although it differs in appearance from pounded lump sugar, it is in other respects identical with it, and is, therefore, equally well adapted for bee-food.]

EARLY POLLEN GATHERING.

THURSDAY, the 30th of January, was with us one of those beautiful mild "pet days," with the thermometer about 50°, which sometimes appear like "a green oasis in the desert" of winter, agreeable to all as the harbinger of spring, and peculiarly so to the bee-keeper to visit his apiary resounding with sweet melody, and note from hive to hive with satisfaction the gambols of his favourites, and their busy stir removing the dead and debris, speaking emphatically of live queens and prospective success.

Taken rather by surprise to notice within a few minutes to five that afternoon brisk arrivals and departures from the frame-hive, to which I made the ineffectual attempt of introducing the Devon hybrid queen, first suspected pilfering; but there was a something in the whirl of the arrivals that sounded somewhat of summer ladings, and prompted a minute scrutiny, when, lo! their baskets sparingly loaded with dark-coloured pollen. My next surmise, Could the Devon monarch have after all supplanted her native rival, and was thus impelling her Scotch subjects in forgetfulness of their "canniness" to issue forth in bleak January to cater for her young fry? This supposition was strengthened by observing a perfect stillness in the hive on either side, subsequently weakened by witnessing a hive proceeding going on in a different part of the apiary the same afternoon in one of the hives of my poor "beat-ants."

By being in a position to report pollen-gathering last spring, on the 3rd of February, I quite astonished "A NORTH STAFFORDSHIRE BEE-KEEPER," as well as Colonel Newman, who

learned with surprise that we northerners had nearly a fortnight's start of his salubrious Cheltenham. At the same time I expressed the opinion that "one hive suspected being so employed for eight or ten days previously, from the business-like air with which they set out late in the afternoon," which this season's procedure has confirmed. From the dark-coloured substance not being so easily detected, the late labour affords the best cue to its discovery. The term pollen to be here received not in its horticultural but apicultural sense, as on the 30th ult. we had only a few acornites in bloom unhealed; our bees in this neighbourhood being in my opinion indebted for their earliest supply to the exudations from the swelling buds of the plane tree.—
A RENFRESHIRE BEE-KEEPER.

THE CROSS BETWEEN ENGLISH AND LIGURIAN BEES.

Do the half-bred bees resemble most in their habits, in colour, and in general appearance, their English or their foreign parents?

Do they always present a perceptible combination of the two tribes, or are the peculiar characteristics of their ancestors on one side ever cancelled or made to lie in abeyance?

Have they been bred both from Ligurian queens crossed with English drones, and from English mothers and Ligurian fathers? and if so, do the half-bred bees, the produce of female Ligurians, differ from the bees whose sires were of that kind, and whose progenitors on the female side were of our English black breed?—W. H.

[We have not had sufficient experience with these hybrids to reply fully and dogmatically to the various inquiries of our correspondent. We believe that the worker offspring of a hybridised queen bee will generally be found to vary very considerably in appearance. Some do not differ perceptibly from pure Ligurians, whilst others are not to be distinguished from the common species, and in the remainder are frequently to be found every intermediate shade between the two. Mr. Fox, and "A NORTH LANCASHIRE BEE-KEEPER" (possibly also "A RENFRESHIRE BEE-KEEPER" may be added to the list, since we believe it is not quite certain that his Devonshire hybridised queen fell a victim to the fury of the native Scotch bees) possess black queens which have been fecundated by Ligurian drones. Probably one of them may be kind enough to reply more fully to the above queries.]

APIARIAN NOTES.—No. XV.

MY APIARY IN 1861 (continued).

No. 10.—As previously mentioned, this straw hive, kept through the winter and miserably weak in spring, was destroyed. Four of the largest combs were at first fixed in Langstroth-frames; subsequently, with a fine queen and a very small number of bees, were added to the combs of the driven hive No. 6, under which name it is now known.

Of No. 6 I need only say, that when this was accomplished the bees were far from being capable of covering the whole of the very large quantity of brood, a considerable proportion of which must have been sacrificed if more nurses and h-at-sustainers could not be obtained. This desideratum was attained by transposing this hive with No. 11, a newly-stocked Langstroth-box, by which more than two-thirds of the population of No. 11 was obtained. This evil was rectified, and the proper balance of numbers given, by reshifting the two hives and returning them to their original positions a few days afterwards, the young bees fast hatching from the cells helping to sustain a fair equilibrium. From this hive, which I did not allow to throw off a natural swarm, I occasionally removed full frames of brood and honeycomb, and on one occasion deprived it of nearly all its inhabitants for the purpose of strengthening other artificial stocks; nevertheless, in the autumn it was exceedingly strong in bees, and almost entirely filled with sealed honey, besides affording me a small quantity for the table.

No. 10 having ceased to exist, its place and number in my apiary was soon awarded to a successor; the history of which must now be told. Its first appearance on any stage was a very insignificant one. On May, the 15th, the day following the transference of the combs of No. 6 into the Langstroth frame-

hire, I chose from it one of the most favourable-looking brood-combs, and, after brushing off all the bees, placed it in a small four-frame box, styled by Langstroth a "nucleus." Adding three frames containing a little empty comb, I removed from its stand to another part of the garden a straw hive (No. 12), when a good many bees were out, setting the nucleus (No. 10) in its place. Though at first very excited and uneasy, the bewildered bees at length began to cluster about the brood-comb, and on the 21st, three days afterwards, I had the satisfaction of finding a royal cell in a state of considerable progress. I may here mention that it is not considered good practice to brush off the bees which are attached to the comb; but, having ascertained that the queen is not among them, to transfer them, as little disturbed as possible, into the queen-raising nucleus. But in the present instance the plan adopted succeeded well. On the 22nd I received a present from Mr. Woodbury of an unimpregnated Ligurian queen, one which hardly reached his standard as to appearance, and which also exhibited some little sign of a defect in its wings. She was confined in a small, perforated zinc, queen-box, which was fixed among the combs, and was liberated the following day. On inspection a few days after I found several additional royal cells in various stages of progress. At first I imagined the queen must have been destroyed, but soon discovered her racing over the combs, the bees paying her little or no attention. The deformity in her wings was now much more discernible, and considering that she could never become impregnated owing to her inability to fly, I judged it best to destroy her.

A fine young queen emerged from her cell on June 3rd, and quickly destroyed the inmates of the remaining royal cells.

On June 19th, having laid a considerable number of eggs, she was removed from No. 10 to be placed at the head of a stock, No. 13, from which all the bees had been driven to form an artificial swarm. The indefatigable bees of No. 10 on discovering their loss immediately took steps to repair it, and from the eggs laid by the queen, whose reign over them had been so limited, they selected two, which were duly provided with the necessary food and apartments. But these were not destined to arrive at maturity; for my friend, Mr. Woodbury, presented me with two Ligurian royal cells—supernumeraries from one of his queen-raising hives. I, therefore, cut out the two from No. 10, and substituted those of Ligurian origin; believing that, notwithstanding the absence of Ligurian drones in my apiary, I should thereby improve my stock.

On July 5th a fine Ligurian queen being at liberty, the frames were transferred into a full-sized Langstroth-box, and other frames with combs were added. The offspring of this queen are to all appearance perfect Ligurians, and the hive promised to become a first-rate stock; but late in the autumn, it is much to be feared, that during some manipulations, more from motives of curiosity than necessity, the Ligurian mother's life was sacrificed, as I have been unable to discover her on several inspections. The bees are still numerous, and in themselves do not exhibit any sign of being queenless. On some fine warm day I hope to have another careful search, and if she is not to be found some steps must be taken to prevent the sacrifice of this excellent stock.

No. 11.—At the time of the April inspection previously mentioned, this was a strong stock in a common straw hive located in my town garden. Having, through the kindness of Mr. Woodbury, been favoured with the perusal of Langstroth's admirable work, I resolved, after well considering the subject, to adopt his principles, both as to hives and general management. I was also anxious to possess so valuable a work, and was fortunate in obtaining a copy through Mr. A. Neighbour. I fear the book is at present out of print, which it is to be hoped will not be the case very long, as it is a first-rate production of a first-rate bee-master.

Some modifications as to dimensions and other minor particulars better calculated to suit our climate and honey capabilities, were deemed necessary; and when, after due consideration decided on, have been adopted without any material alteration in all the boxes I have had made. The chief ruling principle in the system is that of bar-hives generally—viz., that every frame shall fit equally well any situation in any hive. The internal capacity and form of the boxes may vary as suits the fancy or district of each proprietor. I have nine of these hives at this time, all stocked by artificial swarms, or by transference of combs and bees from straw hives, during last summer and autumn.

No. 11 was the first experimented with. On May 4th I drove out all the inmates of the straw skep, allowing them to remain in the empty hive on their proper stand while the combs were carefully cut out, fitted to the frames, and kept temporarily in place with small strips of wood and lead wire. When the combs were bent, they were straightened by holding near the fire for a short time, and placing between two boards with a small weight on top until sufficiently cool. Where too thick to allow the frames to approximate close enough, the surfaces were pared with a sharp knife. Only six or seven frames could be furnished with the combs cut out from No. 11; but small pieces of empty comb were attached to the remainder, making ten in all. When arranged to my satisfaction, or as well as the inequalities of the combs would allow, the box was placed on the usual stand; by a smart rap or two the bees were dislodged from their temporary position in the straw hive, and falling on the tops of the frames quickly found their way down among the combs, delighted to return to their old but somewhat dilapidated quarters. The cover was put on, and they were left to their own devices. The next day the combs were found to be firmly attached to the frames, the wires and other extraneous supports were removed, and a little more paring was necessary where the surfaces were united to each other. For several days subsequently a little attention was requisite before the combs, which had been very thick at the edges, and rather irregular in their old hive, could be reduced, so as to be sufficiently straight in the frames, and of manageable thickness.

From this stock several frames full of brood, as well as many adult bees, were removed for the purpose of making and strengthening artificial swarms. Two supers of the primest honeycomb, weighing 24 lbs. nett, also fell to my share.—S. BEVAN FOX, *Exeter*.

(To be continued.)

THE CHEMISTRY OF HONEY.

"Honey is formed or naturally deposited in the nectaries of flowers and is extracted from them by the working bees; they deposit it in their crop or honey-bag, which is an expansion of the œsophagus, and from this receptacle they discharge it again when they return to the hive. In the interval it is probably somewhat altered by admixture with the liquids which are secreted in the mouth and crop of the insect, so that the honey we extract from the hive may not be exactly the same chemical combination as when it was sucked up from the flowers by the laborious bee."—*Johnston's Chemistry of Common Life*.

I REGRET that the Editors of THE JOURNAL OF HORTICULTURE should have declined being umpires in the matter of the unmistakable change which takes place in simple syrup during its sojourn in the stomach of the bee. My experiment would certainly have been one from which the possibility of error would have been excluded; and I now give the particulars of it in the hope that the Editors will either reconsider their decision, or name some other tribunal to which the question may be referred.

I have an artificial swarm made so late as the 9th of last August, after the honey-harvest here was entirely over, and supplied with a large quantity of simple syrup, by the aid of which they fabricated such combs as they possess. It is one of these new combs, which being themselves made from lump sugar alone, and never having had any stored in them, must necessarily be perfectly free from the "reek" of this latter substance, that I again offer to submit to Mr. Taylor and the Editors of the JOURNAL OF HORTICULTURE, or such other competent tribunal as they may point out.

Having, therefore, offered most conclusively to prove my own case, I now challenge any bee-keeper to prove the converse of my proposition by producing a piece of comb in which simple syrup—*i.e.*, lump sugar and water only, has been stored and sealed by bees, and in which the syrup remains in every respect unaltered. To any one who can do this I will at once present a good stock of Ligurian bees.

That I have not pronounced an opinion on this point without sufficient warrant, will, I think, be evident when I state that during the last two years I have administered to my bees about half a ton of simple syrup which I have been in the constant habit of tasting both before and after it was deposited in the combs, and have invariably found that it underwent a very marked change in the stomach of the bee. In fact, whether placed in old combs or in new ones, it never failed to manifest the peculiar characteristics of true honey.

The mistaken ideas on this point which have been promulgated by such high practical authorities as Dr. Bevan and Mr.

Taylor, were probably owing to their feeding bees with strongly-flavoured compounds, in which the delicate change effected by the secretions of their little labourers would, of course, be entirely imperceptible. It has long been held altogether impossible to "make a silk purse out of a sow's ear," and we need not, therefore, be surprised if bees have failed in making honey either from sugared ale or from sweetwort.—A DEVONSHIRE BEE-KEEPER.

[Such a demonstration would be quite conclusive. If an artificial swarm be formed and be confined in a room having access to nothing but simple syrup formed of lump sugar and water, and out of this the bees form their combs and fill them with honey, then we shall consider their power to form honey from sugar clearly proved, and shall be thoroughly pleased to have elicited the truth on this disputed point. The quotation from Professor Johnston's "Chemistry of Common Life," does not prove the fact, he merely says that it may be so.—EDS.]

BEEES IN THE EAST INDIES.

It now does it happen that wax in our hives melts at a temperature just above 100°, whereas in the centre of Hindostan, where the temperature of the air often is higher, the combs of wild bees remain unsoftened?—SAHIB.

[There is no doubt that the melting-point of the wax prepared by the wild bees of Hindostan is somewhat higher than that of the wax prepared by European bees. This is only one among a thousand instances of animals adapting their surroundings to circumstances, and is one of these instances in which their proceedings approximate to the proceedings of man to secure a similar object; for more shellac is put into sealing-wax for East Indian correspondence to render it harder—that is, to render it less liable to melt.

The bees of Hindostan, moreover, adopt other modes of keeping their combs from melting. They never construct them in a hollow tree, or in a cavity of a rock, but on the shady side of a rock, and under a projection of that which increases the shade and shelters the comb from rains, so that it is fully exposed to the air, and thus is kept as cool as the climate will permit.

The bees of Hindostan are far more vindictive and fierce than their European relations, and charge without the slightest provocation given them, in hosts upon any one who approaches their place of suspension. The native boatmen, naked as they are, are marvellously on the alert to save themselves from such attacks. Their bugerons and other river craft go most tediously slow, so the boatmen always have thick woollen clothes at hand, with which they closely envelope themselves whenever assailed by these dreadful insects.

"Dreadful" is not too strong a term, for we know of more than one death being occasioned by their stings, not only to animals but to men. One such death occurred near Jubbulpore to one of the civil engineers of the Great Indian Peninsular Railway. Two of them, named Armstrong and Bonington, were surveying, and in their progress came near to a bee colony on the Marble Rocks. The charge of the bees was instantaneous, and the engineers fled for shelter to the Nerbuddah River which was at hand; Armstrong, by swimming and diving, escaped with little injury, but Bonington, who could not swim, was so severely stung about the head as to die in consequence.]

EFFECTS OF INTERBREEDING.

Will "B. & W." kindly state if the "increased activity" of which he speaks in page 365 does not take place almost immediately upon removing bees to or from a distance, and long before the issue of a swarm warrants the aparian in believing that any infusion of "new blood" has actually been effected? Also why he does "not think that a mere removal from one locality to another can entirely, or even chiefly, account for this increased activity," when all the evil effects of the only undoubted case of interbreeding with which we are acquainted, here, according to his own showing, been completely and entirely averted merely by swarms roving to and from distant localities?—A DEVONSHIRE BEE-KEEPER.

[In reply to the above queries, I am quite ready to admit that increased activity apparently takes place "immediately upon removing bees from a distance," which I attribute to

change of climate or pasturage, or both. Moreover, I cannot speak with certainty as to the effects of cross-breeding from any facts which have come within reach of my own experience. As I stated at page 368, "this, I fear, must remain open to speculation only," at least till we have some data on which to found a "belief;" and yet I think I remember to have seen it stated in print, that hybridised Anglo-Italian bees have proved themselves in every respect superior to the pure varieties from which they spring.* I venture no more, however, than to claim it as an open question. If I incline to the belief I have stated, it is partly because I see no reason why bees should be an exception to the rule which seems to prevail throughout the animal and vegetable world; and partly because we know that bees do migrate more or less every year to and from more or less distant localities, and do cross blood with their neighbours. In the case of the bees of Tasmania, where thousands of swarms have annually for forty years at least shifted their quarters from the plains to the mountains, changing both climate and pasturage, I am disposed to think the effects of their interbreeding as descendants of one family, almost tantamount to the cross-breeding of other animals which have descended at a more remote period equally from "one blood."—B. & W.]

SUPER-POSING.

I WROTE you last autumn about joining my Ligurians with a hive of common bees, and not receiving a very favourable reply as to the result to be obtained, I did not like risking my Ligurians; but having two old common hives of bees, I thought I would try them, as the straw of both is nearly rotten. So, putting an adapter-board on to the one full of honeycomb and bees, I set the other one full of comb and bees, but very little honey, on the top; then gave them a few puffs of fungus smoke; left them for the night, but found the next morning a good deal of fighting had taken place. Then came off a few cold days, when the bees never showed themselves; but when a few warm days came, they commenced fighting again, and a good many dead bees were thrown out; but I could not find a queen among them, and I occasionally took the top hive off to see if all had joined, when I found bees in both hives; and during last month I looked again, and still found they had not joined, and on Tuesday, the 4th inst., being a very fine day here (South Durham), most of my bees were out, and on Wednesday, the 5th, I found the dead queen on the alighting-board. Since then we have had it too cold to look into them to see if they have now joined, but intend doing so the first mild day.

Now, as to super-posing. If any (many) of your correspondents are right and many wrong, as I fancy, had I have made the opening between the two hives larger, and joined them sooner during warm weather, and the top hive having a good supply of honey and comb as the cold weather came on, they would have gone up. But if both hives be left till summer they will, I think, make the bottom hive their breeding-place, and store in the top; but as soon as the weather is a little warmer I will look at them, and let you know the result. But I am told by a very old bee-keeper that had I put the two hives together—that is, the two bottoms, leaving a place between to go in and out, giving a few puffs, and letting the hive I wanted them to go into be at top, that they would have soon had done so without fighting; and I am inclined to try this plan another time.—A. W.

[Our correspondent's story brings forcibly to our recollection our own tragical experience in super-posing, which has caused this operation to become obsolete in our apiary. We shall be very curious as to the results of the experiment—whether one queen still survives; and if so, in what hive she has fixed her abode. However this may turn out, we feel bound to admit that our northern friends have placed the question in a new light, and have adduced facts which had they before come under our notice would certainly have made us hesitate before expressing so decided an opinion. There is no doubt that if left united during the next summer the lower will become the stock-hive, as stated by "A. W.," but this is not exactly the point in debate. We have always placed the inferior hive on the top,

* The production of hybrids between two different species or varieties of bees, of course, a very different affair. I have, indeed, reason to believe that these hybrids are decidedly superior to the common species. Whether they are an improvement on the Ligurians is very doubtful, and, like the "effects of interbreeding," may well be deemed "an open question."—A. DEVONSHIRE BEE-KEEPER.

with communication through a two or three-inch central aperture, relying that the bees would in this way be compelled to unite in the lower one, and in this expectation we have never been disappointed. We are now told by our northern correspondents that with unrestricted communication (forming, in point of fact, but one hive, and aided, possibly, by the inferior one being at the bottom) the lower hive may at some time during the winter be found deserted by its occupants, and removed without difficulty. We can readily imagine that under these altered circumstances the result would be as they state, owing to the instinct which impels bees to congregate during winter immediately below, and in close contact with, the lower edge of that part of their combs which contains sealed honey, contracting their cluster and gradually getting nearer the top of the hive as their store diminishes during cold weather, but immediately extending themselves downwards towards the entrance when encouraged to do so by a few hours' milder temperature.

Having thus summed up the conclusions, which we think are to be arrived at as the result of this protracted controversy, we may be permitted to hope that all hasty expressions which have transpired may be considered regretted and withdrawn. In apian science we may be well assured that all have something to learn, and however we may differ in opinion, we should never lose sight of this fact, that in these little discussions it is far nobler to endeavour to ascertain and establish the truth than to contend for victory.]

THE COMMON BEE AND NATIVE BEE AT MELBOURNE, IN AUSTRALIA.

IT HAS ALWAYS been a matter of surprise to me that so little attention has been paid to this really useful little creature. It is the exception to find them located either with the farmer or market-gardener, instead of which there ought scarcely to be a garden without them. Both the farmer and market-gardener appear to think the little creatures beneath their notice, or that they are more trouble than they are worth; but I think I can prove that if properly attended to they are highly remunerative. At the commencement of last season I had five hives; but, from some cause or another, one of them did not swarm, so the increase was from four only, and from these and the swarms that swarmed again were thrown off the large number of twenty-three swarms. Of these, three got away and one stock died, so that at the present time the stock consists of twenty-four hives (not all in my possession, for eight were given away, which increased to ten). The weight of honey, taken in glasses and boxes from the tops of the hives, was between 140 lbs. and 150 lbs., which, from its purity, is worth double the price of that taken from the hive itself, and which can be removed without disturbing the hive at all.

As a proof of what each will do, I may mention that, from the hive which did not swarm, I took from the top 40 lbs. of honey, and I suppose the hive itself weighs 40 lbs. at the present time. They commenced to swarm in October. On the 4th of that month three swarms came off, but two of them alighting on the same bough, joined together and made one. These were put in a hive, and in rather less than six weeks had swarmed again, and I took off a glass containing 13 lbs. of honey. The profit on them I calculate thus:—

10 swarms at 30s.	£15 0 0
5 do. at 20s.	5 0 0
4 do., at 15s.	3 0 0
3 got away	
1 died	
—	
23	
140 lbs of honey, at 1s. 6d.	10 10 0
	£33 10 0

This, of course, is supposing the swarms were sold at the latter end of the summer; but if they were sold earlier, there would not be so much honey—say by one-half. Possibly through the winter two or three hives might die; then, too, as bees increased, both swarms and honey would fall in value; but even supposing they did to half what I have reckoned them at, there is still left a very good inducement for their cultivation. I am quite certain that if they were properly attended to there might be tons of honey exported every year. It is a mistaken notion that bees require no attention; although it is not much, they do require some, and they will not thrive unless that attention is paid them

They should be put in good hives, and placed in a suitable situation. Till lately, and even now it is thought by some that anything is good enough to put them in, and ten to one if you see them in the country you will find them in an empty gin case. Some time ago I was at a place where bees were kept, but a complaint was made that they did no good. I asked to see them, and there was the gin case, with the bees going in and out, but very sluggishly; and well they might appear so, for on turning it up I found it to be in a very dirty condition—one was occupied by the bees, while a very fine spider had domesticated itself in the other. I cut the box in two, cleaned the bottom-board, and placed it on the stand again. They are more easily managed at swarming time than is generally imagined. Being engaged during the day in Melbourne, I could not attend to them myself, and so left them very much to the care of the servant. They can be removed from one place to another with the greatest ease. When the John Williams was last here, I gave Mr. Buzacot a hive, which he took on to Sydney, with the view of getting them on to the South Sea Islands. He wrote to say they got to Sydney all right. It is his intention next year, when the vessel visits that port, to send some on to the islands, and I have every confidence that the experiment will be successful. I have heard it said that bees do not thrive on the sea coast, but the above results having been experienced in Brighton fully disproves such an idea. In conclusion, I would take this opportunity of drawing the attention of the Acclimatisation Society to the native bee—a small insect, I understand, about the size of the common gnat, stingless, and collects a good quantity of honey. I am not aware that any attempt has been made to domesticate them. During the coming summer I intend, if possible, to procure some, and I should like to hear of others making the attempt. The natives can easily track them, and for a consideration would, no doubt, be very glad to supply them.—E. BAINES.—(Melbourne Argus.)

[We shall be obliged by any of our readers furnishing us with more information concerning these Australian stingless bees, which we also wish merchants trading thither would take steps for importing into this country.—Eds. J. or H.]

COD LIVER OIL FOR DOGS.—Possibly some of your readers may not be aware of the efficacy of cod liver oil as an alterative and strengthening medicine for dogs, given once or twice a day, in doses from one table-spoonful, according to size and age; it works wonders in weakly puppies, wasting of flesh, and indeed in debility of any nature. Give the oil either mixed with milk or broth or after feeding. Some dogs will lick it up greedily, but generally they seem to dislike the flavour.

OUR LETTER BOX.

GAME COCK WITH NAIL-TIPS TOY A. D.—The loss of the nail from the toe would not be a disqualification to your bird, although were the competition close, it would tell against him. If the toe becomes swollen and deformed, it would be useless to exhibit him.

SPANISH COCK'S FACE TURNED RED R. C.—The face of a Spanish cock will become rusty sometimes in very cold weather, but not red. There is no hope that a red face in an adult cock will ever become white.

BLISTERS ON FACE OF SPANISH COCK. (Newest Subscriber)—The cases you name belong to a very common disease among Spanish fowls, especially cocks. The cure is easy. Dress every spot with compound sulphur ointment. While they exist the cocks should be by themselves, as the other birds peck the sores. Wooden floors are objectionable; first, be sure a fowl's foot is always kept in an unnatural position from the unyielding nature of the material; next, because they cannot scratch on it; and, lastly, because it is always damp and cold. As advertisements say, "One experiment will prove the fact."

PROFITABLE POULTRY STOCK.—*Wester* will oblige by sending his name and address to Mrs. Bard, 3, Victoria Street, Finsbury, S.W.

COCHIN-CHINA CHICKENS' LEGS PARALYSED (Young Darwin)—We give all our chickens strong beer at this time of year. If your chickens fast from dawk till daylight it is too long, and may cause cramp or any other disorder. It is six or eight fastings against eight feedings. Take a canle and feed every night at four and ten, or at the latter hour only. It will occupy only a minute or two, and they will learn to look for you as you do for your dinner. How many chickens has each hen? Discontinue the canary-seed and rice.

POULTRY KEEPING (A Subscriber, W. Ford)—Six hens are not too many for one cock. There is no special keeping for fowls to be exhibited more than we state, fully in Nos. 683 and 684, which you can have free by post from our office for eight penny postage stamps. Cochons diet and warmer weather will restore your Spanish cock's comb to its natural red colour. Have nothing to do with incubators. Two or three Cochon-China hens will soon furnish you with a broody mother. For seven penny postage

stamps you can have free by post from our office, "The Poultry Book for the Month." It gives much information which you will find useful.

GAME HEN WITH SWOLLEN HEAD (C. L. PA.)—Shut your hen up in a warm place, feed her on soft food and cold beer soaked in a. w. wash her head with vinegar and cold water, and give her frequent doses of castor oil.

LEGS OF GOLDEN-NECKED HAMBURGERS (Green Legs)—They must be blue; green legs would insure defeat.

DWARF FEET (W. J. Ganeboy)—Your Game cock has this affection of his feet; it usually occurs in old birds which roost on a high perch, and have brick floors to walk and fly down from. We know of no remedy. To prevent the disease have low perches, and all brick or stone floors covered with sand 2 inches or 3 inches deep.

LEGS OF COCHONS (E. H.)—No application is better than flowers of sulphur dusted among the feathers. You surely might prevent their occurrence by keeping your roosting-places and nests more clean. Have the whole thoroughly cleared out once or twice a week, and wash the interior, having some flowers of sulphur mix in the linowash.

DIVIDING FOWL-HOUSE (Amateur)—It is impossible to divide a pen (you call it a house) 8 feet long, so as to be healthfully used for two sets of fowls. You must build another similar pen in front of the present, and have a wire (communicating with each) down the side of the wire applied with wire, and this run could be used by each set during part of the day, and by the other set during another part of the day. Two cocks would not agree.

INCUBATORS (D. B.)—We do not advise Cantlo's incubator at this season of the year. It is very successful in hatching, but it cannot rear; nor do we think any one can raise chickens without hens till the weather is warmer and the nights are shorter.

CORNISH FEET OF ATLESBERY DUCKS (A Constant Subscriber)—If your Ducks are kept on a paved or brick floor the corns on their feet are not cured for. If the corns are only on the feet there is no real cure for them; but if they are only just appearing touch them with caustic, and keep the birds as much as possible on grass. A Rouen Duck's bill should resemble exactly that of the wild Duck.

SIX OF GOSSINGS' LEGS OF WHITE BANTAMS—GAME COCKS THIMMED (J. M.)—You cannot distinguish the sex of Green Game at five months old. White Bantams may be either sex at any age. A single-legged single or double comb of either sex, the clear-legged should have double combs. If white-legged, white ear-lobes; if yell or-legged, yellow ear-lobes. Game cocks are trimmed before they are sent to shows, but we are not aware that anything is done to their plumage.

TERRENS ROYAL (A. B.)—Your Turkeys, from your description, are very far gone in the fourth. Those that have the large lobe on you mention it would be well to kill. For those that are highly affected we would recommend an entire change of diet. Feed them entirely on soft food, do not cut with onions chopped in it, and a little black pepper mixed with it. Trim let them have much water. Wash their heads and mouths with vinegar and water; and where the tongue is hard, white, and horny, trim it round with a pair of scissors. Salt pills may be given with great advantage. The house where they roost must be kept clean. Give them strong ac.

SIZE OF HIVES AND STEPS, ADVANTAGES OF BAR-HIVES, AC. (A Suffolk Subscriber)—1. Thirteen inches square by 8 inches deep inside, is a good size for stock-boxes. 2. We prefer squares of the same diameter, but varying slightly according to the season. 3. The best communication between the stock-hive and a super is formed by two half-inch slits in an adapter near the sides, as long and as wide apart as the diameter of the super will permit. 4. Among the advantages of bar-hives (which belong also to a greater extent to frame-hives) are—The power of raising or taking anything is wrong, and enabling a remedy to be immediately applied. Weak stocks may be rapidly strengthened by either changing one or more empty combs for brood-combs from a strong hive. Food may be supplied in the same manner. The number of droves may be limited by removing all but a small portion of drove-comb, and substituting worker-comb in its place. Economy in wax, by enabling every lot of worker-comb to be turned to good account. Facility in making artificial swarms, as well as all other apian arrangements. Eggs should run through a No. 50 comb. Comb-frames should be secured by a bent knife. Complete frames are preferable to the side-slips you propose, and should be kept three-eighths of an inch from the top, sides and floor board. The plan of double wood with a space between for air has often occurred to us, and although we have never tried it, we are disposed to think it a good one.

AUSTRALIAN GAME FOWLS—LOVE BIRDS (A Correspondent) wishes to know whether the best Australasian Partridge breed in confinement in this country, and to have some directions for their management, and what ought to be given for a pair. Also, the same information about Love Birds.

LONDON MARKETS.—FEBRUARY 17.

POULTRY.

As the time of year creeps on, the supply of poultry diminishes, and the lack of quality shows that the approach of spring is not without its influence. It is almost an inappreciable step from the putrification of the fowls of the Game season and the opening of Parliament cause a slight improvement in trade, and consequently, in price.

METEOLOGY OF THE WEEK.—At Chiswick, from observations during the last thirty-five years, the average highest and lowest temperatures of these days are 48.3 and 33.7 respectively. The greatest heat, 64°, occurred on the 25th in 1849; and the lowest cold, 15°, on the 3rd in 1851. During the period 129 days were fine, and on 10 rain fell.

MISTLETOE PROPAGATION.

VERY quarter of a century there seems to be a mist about the Mistletoe, which comes lower down and rises with a tide-like regularity. Five and twenty years back, the backbone of the gardening of all Europe was bent down with the weight of the art and practice of sowing the Mistletoe seeds, of propagating the Mistletoe from a budding-like operation, and of grafting it exactly as Apple and Pear trees are grafted; and there was then a nursery not far from the heart of mid-England, in which standard Mistletoes were grafted, tied, untied, pruned, trained, and sold as regularly as any branch of the trade ever was or ever can be carried on, and the Oak tree was full of Mistletoe. The largest specimen on that tree was full 5 feet in diameter, and the last newest member who was elected as one of the Council of the Royal Horticultural Society is the owner of that tree.

I say our books and backs were then loaded with accurate accounts of all that, but now the subject is as if it were not, and there is yet one thing at least about Mistletoe which will be a new thing under the sun, if you believe what comes from under this cloud of mist. Even your humble servant could not resist the spirit of the testimonies to what was true of Mistletoe; and I grafted, budded, and sowed Mistletoe then, and put it all in black and white, of course, as I always did and mean to do to the end of the chapter.

There was a wave in the edge of the misty cloud about the birth-time of the old COTTAGE GARDENER, and I recollect very well having had abundance of "private correspondents" in this country, and in Ireland, and one or two places in Scotland, for packets of fresh seeds of Mistletoe, from the front of the conservatory at Strubland Park; and now I shall be a public correspondent asking how the seeds I sent behaved themselves. Probably if one had time to look over the first few volumes of that or this work, he would find all that is needful to be known about the Mistletoe and how to grow it. But once on a time the plague of my life was to discover a process by which to undo Mistletoe. I could not get rid of it anyhow, and I hold it in my creed that you cannot get free from it after it has been in possession of your trees a long while, without first ridding yourself of all the boughs and branches on which it has taken. You could overcome the vitality of Horseradish by not leaving a bud of it in the trenched ground. But the vitality of the roots of Mistletoe is such, that the ground itself, as it were, must be removed ere the roots cease the root action, which is beyond the power of the root action of any root in the ground.

Dear me! it seems but yesterday that Dr. Lindley and Mr. Loudon were preaching all this from the balcony of a lustings hotel to the independent electors of self-taught and glorification, and now we have none of them—a good job too, for self-glorification is as the mist of Mistletoe. Quite sufficient of it to get over one's nerves once in five and twenty years.

Well, the nursery at which Mistletoe standards were made and sold was at Great Malvern, near to the confines of Worcester, Hereford, and Gloucestershire, and not an individual in the three counties but knows Great and Little Malvern; so the doing was not done in a corner. Besides, London has the very start of the practice in the "Gardener's Magazine" for 1837, page 206, and for the next two or three years the proceeding was not out of people's mouths. The nurseryman was Mr. Moss, and Mr. Moss was gardener at Eastnor Castle for thirty years. The first thing he did on the Mistletoe question, was to establish the truth of the fact that Mistletoe will grow on the Oak, by giving the Oak branch which was sent to the Horticultural Society's Meeting in Regent Street, through Mr. Loudon. It was the second largest specimen on that Oak, and there were several smaller ones. About two miles from Eastnor Castle there lived a master grafter of drink fruit, or victuals and drink, as the workpeople there say. Mr. Pitt of Little London, grafted other than fruit trees. He "grafted all manner of things," as he often told me himself, and he was then about the same age as I am now. He was the first who showed a gardener how to graft and bud Mistletoe, and the said gardener was the first person who taught Mr. Moss what he did with Mistletoe at Malvern. Little London, as you go from Ledbury to Gloucester, and three miles from the former, was then before big London in the matter of Mistletoe.

The Mistletoe was much more flourishing and fresh-like on that Oak than on any Apple tree in the country. But to make a short story of a long one, the middle of May is the best time to graft the Mistletoe, and from then to midsummer. The best grafts are three-year-old shoots of the Apple tree, with a seedling Mistletoe on it already from the sowing of a thrush or blackbird, and the best way to graft it is to cut off all the leaves of the Apple-tree graft, and to leave at least four eyes, or buds, before the Mistletoe seedling, and only as much wood behind it as will be sufficient to make the union with the stock and no more; to have it done 5 feet high from the ground, to clay the graft in the usual way, to moss the clay, and to keep the moss damp, and to have the Mistletoe seedling just resting or nestling in the top of the ball of moss. Another most particular thing is to have one or more shoots left on the stock and above where it is grafted, and to let that shoot have all its leaves on. If the weather is very cold, or very hot, or windy, put a brown paper cape over the ball and Mistletoe, and nineteen out of a score of them ought to grow by this, "the best way."

I have grafted the Mistletoe itself on a Balsam Poplar, the very first one I ever did, Mr. Pitt standing over me

at the time. That was some time in April, at the height of the grafting season in that county. Grafting pieces of Mistletoe is like budding exactly, but make a longer and a wider slit in the bark, and make the Mistletoe stem in a flat wedge-shape on one side, and put in the flat side next the wood of the stock, as in budding. Tie, clay, and moss, and cape with brown paper, and you are in for it sure as he was, or Mr. Moss either.

To bud Mistletoe is merely to take a less piece than the graft, only one joint of Mistletoe, "having a bud and one leaf at the end," but clay it and moss it, and paper-cape it as if it were a graft.

Now, in respect to the subject which forms the text for this article—the sowing of the Mistletoe seeds in a slit made in the bark of the plant, or merely on the surface of the bark, without the slit. Both ways are equally good, for it is not where the seed is placed that the Mistletoe seedling plant takes hold. A much more curious thing occurs at the germination of the seed of a Mistletoe. Sometimes there is only one germ in the Mistletoe seed; in others there are two, three, four, or more germs, and each germ throws up a sucker on the end of a short stalk. The sucker then lays hold of the bark of the tree, and holds on to it for six, or eight, or more months, according to the time of the year; but it is from this sucker that roots penetrate the bark, and not from where the germination of the seed took place lower down. When there are more embryos than one in the one seed, there are as many seedlings from one seed as there are germs; for each germ, or embryo, has its own branch and sucker, and each sucker takes an independent hold for itself, and on the place it holds to a seedling plant is established. I have seen three good plants thus from one seed, and each of them was half an inch in advance of the seed itself.

The seed of Mistletoe will vegetate on the bare handle of a house-broom quite as readily as on the bark of an Apple-tree branch. If you fasten it with a bit of putty on a deal board, moss, and moisten it early in the summer, it will also vegetate on the board or on a bar of iron; then it dies, for the suckers at the end of the roots, as you may call them, find not a proper place to fasten to.

The belief and notion on this subject were very different from what is stated at the time referred to—five and twenty years back. They amounted to this, as far as I recollect: That Aristotle and Pliny among the ancients, and Dr. Walker among the moderns, considered that the Mistletoe was propagated by the excrements of the birds which had fed on the berries, supposing that the heat of the stomach and the process of digestion were necessary to prepare the seeds for vegetation. Ray first suggested the idea of trying by experiment whether the seed would vegetate without passing through the body of a bird; and at his suggestion Mr. Pooley, an apothecary of London, inserted with complete success a seed of the Mistletoe into an incision made in the bark of a White Poplar tree which grew in his garden. This, Professor Martin observes, has since been done by many persons, both by rubbing the berries on the smooth bark of various trees, and by inserting them in a cleft or in a small hole bored on purpose, which was the mode adopted by Pooley, the first person who really sowed this seed. The celebrated Du Hamel, arguing that the seeds of the Mistletoe, like the seeds of other plants, would germinate anywhere, provided they had a suitable degree of moisture, made them sprout not only on the bark of different kinds of living trees, but on dead branches, on bricks, tiles, stones, wood, and iron, down to mother earth; but though they germinated in such situations, they did not live any time except on the bark of living trees. M. Du Trochet made seeds of the Mistletoe germinate on the two sides of the frame of a window, and in both cases the radicles directed themselves towards the interior of the room, as if in quest of darkness.

These were the things which we, who wrote in 1837, believed in, but the notes are mine; and it was fresh in our memory that Mr. Baxter, of the Oxford Botanic Garden, had in the spring of 1835 rubbed nine Mistletoe seeds on the smooth bark of an Apple tree, all of which germinated. Two of them produced only one radicle each, six produced two radicles each, and one produced three radicles; and when you know there is an embryo, or germ, in the seed of a Mistletoe for every radicle it makes, you may take my word for it that each of these germs makes a seedling plant. From the experiment in the Botanic Garden at Oxford, you may also learn that two seedlings from one seed are more common than either one or three.

Now, do you suppose for one moment, that we who lived on

the other side of five and twenty years back, and knew all that and talked of it among ourselves, can help now being grieved to hear what Dr. Lindley would call "exaggerated nonsense," from the mouths and pens of men as good as ever any of us aspired to, just because folly seems, in some instances, to be less an exaggeration than the real truth? But the profit to you is immense. "Exaggerated nonsense" is by such discussions got rid of altogether, and whatever good is in the story you have it pure and simple without exaggeration of any kind, good or bad, and the good you will have out of this true story will never get out of your mind as long as you live; that good thing is, the knowledge that our craft, rightly applied, will cause a seed, even the seed of a Mistletoe, to germinate and sprout on the face of a bar of cast steel in the bottom of a crinoline; and sure-y, then, no one can fail to do it where it ought and how it ought to be done. You have the "how" from the great physiologist Du Hamel, "a suitable degree of humidity," or, if you like our way of putting it, which is the right way of doing it, have a ball of moss, always as damp as his "humidity," all round the seed to vegetate, and by keeping a nightcap of brown paper over it the while, you lessen the need of so much water to the moss. Some people are so plain in their senses, that they think a seed must grow because it is sown. But you see there are conditions essential to success, even if you sow in a pot or on the border—so much heat, so much of constant moisture, and so much shade, and more of it if you choose. But these three conditions must never be absent, nor any one of them, in turning Mistletoe seeds into seedlings, or grafts or buds of them into plants.

D. BEATON.

[In illustration of Mr. Beaton's communication we extract the following from "Loudon's Gardener's Magazine" for 1837, page 203:—

"The first indication of germination is the appearance of one or more radicles, like the sucker of a house-fly, but larger; as at *h* *i*, which are front views, and at *k* *l* in the same figure, which are side views, taken from Mistletoe berries which were stuck on the upright trunk of a Cherry tree in our garden at Bayswater in March, 1836, and germinated there, as they appeared on the 20th of May of the same year. When the white, viscous, pulpy matter of the Mistletoe berry is removed, the kernel, or seed, appears of a greenish colour, and flat; sometimes oval, at other times triangular, and at other times of various forms. *a* is the male blossom magnified; *b*, the female blossom magnified; *c*, a berry cut through transversely; *e*, a seed divided vertically, showing the two embryos; *g*, the embryo magnified; *h*, the two embryos, with the two radicles germinating; *i*, a single radicle; *k*, a side view, or section, of the two radicles; and *l*, a side view, or section, of the single radicle.

"It is remarked by Du Hamel, that, when the form of the seed is oval, generally one radicle only is protruded; but, when it is triangular or irregular, two, three, or more appear. It is singular that, while the radicle of almost all other plants descends,

this is not the case with the Mistletoe; the young root of which at first rises up, and then bends over till it reaches the body of the substance to which the seed has been attached, as at *K* and *L*. Having reached that substance, the point of the radicle swells out like the extremity of the sucker of a house-fly, or, according to the comparison of Du Hamel, like the mouth-piece of a hunting-horn."]

A FEW NOTES ON VEGETABLE CULTIVATION.

As the enlivening of the most important vegetables has been given in detail in the preceding volumes of THE JOURNAL OF HORTICULTURE, it is needless here to repeat what has already been told. The following notes will, therefore, be more especially directed to certain features, which it is strongly advisable for the inexperienced to keep in view, supposing at the same time that he is versed in the ordinary routine of sowing, planting, and the other ceteras, which after all form the basis of all our undertakings, however skilful or ingenious the further operations may be. In the vegetable department, however, simplicity is the order of the day; and the remarks here given will be necessarily brief, except in cases where a more explicit treatise seems required, and these will be few:—

BEEF.—The White or Green Beet, of which the top instead of the root is used as a salad, has so fallen into disuse since so many other plants of greater repute have sprung up to supersede it, that its culture need not be enlarged on here; but the Red Beet of our gardens, of which so much has been said in former times, and which is far from always being a perfect article now, requires some remark. So much uncertainty hangs over uncertain seed that Beet of the best quality is not always forthcoming when wanted, neither is the appearance of the plant when in a growing state at all a proof that it is likely to furnish good well-coloured roots. I had a good example of this the past season, having two plots of Beet, one with a short top of a deep purple crimson, and plants of uniform growth; the other with a much longer foliage, which in colour was not much darker than ordinary Mangold Wurtzel, being a sort of brown and green streak, and ordinary observers would have predicted a very indifferent article; but it was quite the reverse, being much superior to the other dark-coloured short-topped variety—in fact, it was as good a quality of Beet as I have seen for some years; while the other was bad-coloured and indifferent. So much for appearance in the growing season; and I record this in order to warn the inexperienced against being led away by first impulses, as only an examination of the root itself can determine a good quality, which, as is well known, consists of a dark crimson tuber, free from veins and streaky places; the root need not be too large, as generally a large-sized one is faulty.

Beet need not be sown until the middle of May, unless the season be an unusually forward one, and in that case it may be sown by the 1st of that month. At the time of sowing in the open ground, it is advisable to sow a box or a few pans of the same sorts and place them under glass, as Beet is liable to so many mishaps when in the seed-leaf: thus the crop has frequently to be succeeded by planting, and a few in reserve are useful. It will require thinning at the proper time, and in autumn must be taken up before severe frosts, which destroy it, the plant being more tender than the Carrot or Parsnip. In the growing period, however, it requires but little attention.

BORECOLE OR KALE.—Every year gives us an addition to this useful and numerous family; at the same time some of its members drop off, those in the ordinary lists of 1862 do not much exceed in number those of 1852, or before. One or two old favourites, however, still retain their place—the old Curled Green or Kale, certainly the oldest member of the family, and still deserving cultivation alike for its appearance, hardihood, and table properties. Then we have Cottager's Kale, a very useful and prolific variety; Asparagus Kale, so called from the young shoots when denuded of leaves boiling and eating something like Asparagus, is also a favourite with many. Chou de Milan is second to none for delicacy at table when in good condition; but it is less hardy than some other kinds, while, perhaps, the most hardy of all is that section which has sprung from the old Ragged Jack of our forefathers, one called Luda Kale being certainly an improvement; but this class has fallen into disrepute, except, perhaps, in very exposed cold places. Then there is a variegated Borecole, containing when true all the colours of a rainbow; unfortunately it is apt to sport, but when true is much sought after for garnishing. Some other varieties might be added; but

the above are sufficient to represent an important family, to which Brussels Sprouts stands in the character of first cousin, but this will be treated of hereafter. Suffice it to say that all the members of this household like good living, and make the best return when treated to the fat of the land. Sow as early in the spring as the nature of the ground will allow, and plant out in shallow drills made by the hoe, not less than 2 feet apart each way; an earthing-up afterwards will be of service. The remaining features of their treatment have been already treated on in former articles, and need not be repeated here.

BRUSSELS SPROUTS.—The vagaries of trade, or, perhaps, the waywardness of buyers, has at length contrived to make one or two varieties of this useful article, seed lists containing somebody's Improved, as well as home-grown and imported seed. This is certainly not to be found fault with, as a degeneracy might take place if there were no emulation in supporting rival claims. However, as every one knows a good Brussels Sprout, it is needless to say more than to advise those who grow this vegetable largely (and every one ought to do so, for there is no winter green so profitable), to sow a portion of all the kinds, and keeping them separate, mark the result when autumn and winter come on, and another season only grow the kind that proved best. Generally speaking, I plant as many Brussels Sprouts as of all the varieties of Kale united, for a dish of Brussels Sprouts may be had in all weathers, from October to April, and they often have to act as a substitute for all of them, and in very severe winters for Broccoli too. It is, therefore, proper to say, that too much cannot be said in favour of this plant. Its cultivation is much the same as that of Kale, only it might be allowed a space of 30 inches each way, if the ground be very good. We need hardly say that stripping off the leaves from the stem in autumn, as is sometimes done under the plea of giving the little hard Cabbage-formed heads a better chance to grow, is a very bad practice, and is sure to be attended with reverse consequences, as Nature has pointed out a duty for these leaves to do, after which they fall off. It is, therefore, barbarous to forestall this necessary operation.

BEANS (BROAD).—Hardy, prolific, and everybody's money, this vegetable is somehow despised in the gardens of the wealthy, and thrust into some obscure place where nothing else will grow—most likely under trees. Fortunate it is, that it is so accommodating, and also so grateful; but it is much more so when it is duly honoured with an open, favourable space. But we must leave this to the management of the cultivator; and to the inexperienced it is right to say, that so accommodating is the Broad Bean, that it will stand the winter tolerably well when sown at the end of November, or what will answer the same purpose better, a few pots may be sown in February and placed in heat, and the plants gradually hardened off. They will plant very well in March, and produce a good and early crop. Succession crops may be sown in the open ground as wanted. The best for early use is the Longpod, but the large Windsor is more esteemed at table, and late sowings might be of this kind. Do not plant too thick if the ground be rich, and it is not bad practice to nip off the points of the stalks when they indicate getting too high, as the lower blooms set better. Broad Beans are essentially a cottager's crop, from their not offering so much temptation to birds as Peas do. It is also more remunerative, producing a greater amount of food than its more popular compeer, and in its growth requiring no stakes, unless when by the side of a path, in which case a few upright stakes and a string might keep them from hanging over. The other features of their treatment have been detailed elsewhere.—J. ROBSON.

(To be continued.)

GERANIUM BIJOU AS A BORDER PLANT.

YOUR correspondent Mr. Robson invites attention to "striped borders, and suitable plants to make them with," and says he shall be glad to hear of any addition to his, I think, complete list of plants for the above purpose. I have no new plant to recommend; but, seeing he places Geranium Bijou rather high in his list, as he describes it as the best of the Scarlet-flowered variegated-foliaged kinds, I beg to add a few words in its favour. I have grown it extensively for the last three years, and find it to be the best of its class; it is a free striker either in spring or autumn, good doer, will bear packing very close in winter without the leaves fogging (a great desideratum), as hardy as a common Scarlet, and it grown as a pot-plant will furnish bloom of irre-

propagated all through the winter. I have it in bloom now, and shall be happy to show it to any one interested in these matters. Every body knows and approves of Brilliant, but for very apparent defects as to foliage. Pison is with me as free-blooming as Brilliant, with much larger flowers, and first-class variegation. And now, having sung its praises, let me add a word about its one defect—its legginess. This may be entirely done away with, by pruning back the numerous cuttings in the spring to one or two eyes above ground. If the tops are put in a gentle bottom heat, they will strike with very little trouble, and make as good or better plants than their parents. The plants pruned back will break out strongly, and also become bushy and strong before beddings at time arrives.—H. B.

HEATING BY HOT-WATER PIPES.

I have a small lean-to conservatory at the back of my house, facing north, about 22 feet by 12 feet, and 12 feet high at the back. It is very imperfectly heated by small pipes on Perkins' principle, and the cost of fuel is out of all proportion to the heat obtained. Would one four-inch pipe all round answer to warm it in winter by Camellias, Azaleas, &c. & would there be much difference if the pipes were laid above the floor, or under a getting all round?—R. P.

[We think there must be some fault with the damper, the ash-pit door, the flue, or not enough compression on the small pipes, to cause such a waste of fuel. Of course, the small pipes cannot act as expected unless they become very hot from compression of the water, and the hotter they are the greater the danger. Nothing would induce us to risk using that system. The single four-inch pipe all round will keep such a house safe for what you say, but will not be enough to force much. In taking such a single pipe all round, one-half or two-thirds must act as a flow, and the rest as the return, the piping rising gradually for the flow—say 2 inches or 3 inches, and then sinking to the bottom of the boiler. An open gas-pipe should be inserted in this highest point, and the end left open 5 feet or so above the pipe. The piping will have most power if exposed, but for what you state it will do well enough under an open grating. Of course, you will have a supply-cistern for the boiler, whatever kind of boiler it be.]

NOTES ON A FEW TENDER AQUATICS.

(Continued from page 378.)

ERIOCAULON (Piperaceæ).—This genus contains species which are, perhaps, more curious than beautiful. *E. fasciculatum* is a stove annual of dwarf habit, bearing white flowers, and is a native of Guiana. *E. australe* is a greenhouse perennial, but possessed of little beauty. They thrive to perfection in turfy peat and chopped sphagnum, and the pots set in shallow water. The annual one propagated by seed; the perennial one by division of the root.

HEPHESTIA TRICHA and **MONNETTIA** are both very handsome. The habit of the former is erect, with coriolate leaves, and produces pretty blue flowers in August and September. It is indigenous to Brazil, and some of the West India islands. *H. Monnettia* is of a trailing decumbent habit, with eteaforn leaves, and, like the last, has small pale blue flowers. It is a native of various countries, China, and America both North and South. Both of them are reputed stove species, but I have known the latter flower very well indeed in a warm greenhouse. They require rich soil, and to be set in only a few inches of water. Propagated by division of the roots.

HYDROCELE TRIFLORA is an annual, with piped floating stems rising 2 feet above the surface of the water. It is remarkable for the colour of its flowers, which are variegated with white, red, and yellow. It is very showy and attractive. It is a native of the East Indies. It requires a moderate-sized pot and rich soil, and the pots half immersed in water. Increased by seeds, which should be sown in April.

PISTIA STRATIOTES, or Water Soldier-like Pistia, is a stove perennial of rather a singular habit. It floats on the surface of the water, but does not attach itself to the soil—in the latter particular resembling the genus Lemna or Duckweed, so common in ditches and pools of stagnant water in this country. The leaves are somewhat obcordate, and it produces white flowers generally about the beginning of September. It is propagated

by merely pulling it to pieces, every bit forming a plant. It is indigenous to the East Indies.

HEPERANTHERA ACTUA comes to us from Virginia, and *H. reniformis* from South America. Neither of them are possessed of much beauty. The former has white flowers, and will succeed in a greenhouse. The latter has variegated leaves and blue flowers, and requires stove heat. They should be grown in pots of good rich soil, and set in shallow water. Increased by division.

VICTORIA REGIA has no rival—no equal, amongst aquatic plants; indeed it is hardly exaggeration to say that it is the finest plant in nature. Doubtless all have at least heard of this magnificent Lily; but as all may not have seen it, a brief description of it may not be without interest. It is a stove perennial plant, with floating leaves of almost fabulous dimensions—5 feet to 6 feet in diameter, the margins of which are turned up all round, forming a sort of rim from 2½ inches to 3 inches deep. They are of a deep reddish colour beneath. The flowers are at first white, shading off to pink, and of a deep rose in the centre, and a foot in diameter. It is a native of Guiana and neighbouring countries. The plant was raised at Kew in 1846. It requires a great deal of space, and to be grown in rich muddy soil. It should be kept dry in winter; and when they begin to grow increase the depth of the water gradually until it is considered sufficient, which will not be less than 3 feet. It can be increased either by division of the root or by seeds. If by the latter mode, they should be sown in a temperature of not less than 84°.—J. DUNN.

NAMES OF THE BEST 21 HOLLYHOCKS, IRRESPECTIVE OF PRICE.

Advancer (C), blush, with rose.	Starsted Bival (D., L., & L.), salmon rose.
Cope of Silver (C), white, purple base.	Trumpiums (C), lilac.
Countess Russell (C), rosy peach.	Lady Braybrooke (C), lawn and pink.
David Poulis (D., L., & L.), blue.	Leonora (C), crimson.
George Keith (D., L., & L.), rosy scarlet.	Allice (D., L., & L.), primrose.
Invincible (C), rosy salmon.	Regina (C), clear pink.
Joshua Jarke (C), crimson.	Empress Improved (C), straw, chocolate base.
Lady King (C), ivory red.	Mr. B. Cochrane (D., L., & L.), rosy purple Prince (Roake), purple.
Lady Davies (D., L., & L.), rosy salmon.	Senator (D., L., & L.), deep crimson.
Miss Lizzie King (C), yellow.	Madamingle criticism (C), deep crimson rose, with dark base.
No. 115 Ultra (C), rosy lilac.	Agencia (C), rosy blue.
Prince Albert (C), crimson salmon.	
	(C), Chater; (D., L., & L.), Donnie, Laird, & Laing.—H. H. D.

COCOA-NUT FIBRE REFUSE.

In answer to "A. A. A." we reply, yours is the second sample we had sent us this week of what is as far from the real stuff as Drighella is from Kingston-on-Thames—the only place in the three kingdoms where it is made, and there it is worked under a patent, firm as Chancery Lane. What you sent, and what we had from Bury in Lancashire, is the refuse of the mat-makers and brush-makers, and is entirely and altogether the very worst thing under the sun to put Ferns in. Pray say to yours are you lose them. We said, or rather Mr. Boston has often said, that the cocoa-nut fibre refuse for potting is like mahogany sawdust; but it is finer in the grain and in the touch than the finest sawdust, and as soft-like as sifted peat with a lot of the fibre left in it. You can only get it to Ireland through some great London nursery. A hor's-load of it costs only 2s at the mills; but the expenses attendant on carriage are heavy. When the refuse is put through a cinder-sifter, and one third of its bulk of the finest cinder-ashes is added to it, and well mixed, the mixture is the best for plunging pots in over a warm bath, and for all sorts of plunging for propagation. The Crystal Palace Directors are about trying it for recovering the roots of their large Orange trees, after the leaves and roots were poisoned with gas. Mr. Eyles, for the Royal Horticultural Society, is to have it for plunging purposes to begin with; therefore we shall soon hear of agents enough for it in London and other chief cities. And all this has arisen from a chance private letter we had from a clergyman below Bristol a few seasons back, and which was noticed in these pages.

LUCIFIA GRATISSIMA.—In your Number of January 21st is a description of this beautiful plant growing at Carran, Ireland, covering a trellis 12 feet by 8 feet. You remark, "Ireland has

now thoroughly beaten old England in this instance." This is an error. At Florp Perrow, near Ebdale, Yorkshire, the seat of M. Millbank, Esq., the back of the span-roofed conservatory is completely covered with a plant of *Luculia gratissima*. It is trained up the back rafters and is coming down the front, and annually produces four times the quantity of blooms that the Irish plant does. It is one of the best rafter plants I know, and stands the knife well.—Ebor.

ROYAL HORTICULTURAL SOCIETY.

FEBRUARY 18TH.

FRUIT COMMITTEE.—A Meeting of the Committee was held on Tuesday, the 18th inst., Mr. Edmonds in the chair.

A seedling Grape called *Shakespeare*, was received from Mr. Butcher, nurseryman, of Stratford-on-Avon. It is a seedling raised between Champion Hambrough and Barbrossa, but it is perfectly distinct from both. The bunch is long and tapering, like that of the Barbrossa, and the berries, instead of being round as they are in that variety, are quite oval. The skin is very thick, and the flesh is firm, richly-flavoured, and with a fine piquancy. It was thought highly of by the Committee, and was requested to be sent again. Mr. John Richards, gardener to Lord Lonsborough, of Garatone Park, Tadcaster, sent a box of New Black Hambrough Grapes, which were small in the bunches; the berries were of good medium size, and well-coloured, but the flavour rather acid.

Captain Tyrell, of Fordinghoe, near Ealing, sent specimens of two Apples that had been exhibited at previous Meetings for the purpose of ascertaining their names, but they were not identified. C. W. Strickland, Esq., of Hildingly, also sent several specimens of Yorkshire Apples.

The seedling Apple sent to last Meeting by Mr. Templer, of High Acworth, near Pontefract, was again submitted, but it was not considered of sufficient merit to obtain a Certificate.

A dish of the fruit of *Granadilla* (*Passiflora edulis*), was sent by Mr. Lamb, Osmonston Manor, near Derby. They were fine fruit and in good condition, but their qualities are such that they did not find favour with the Committee as a dessert fruit.

A box of *Momme-Lefort* grafting was sent by Dr. Lindley, and remitted to the garden at Chiswick for trial.

FLORAL COMMITTEE.—Owing to the alterations necessitated by the Exhibition works, this Meeting was held in the conservatory, from whence one could see how thoroughly the great building has spoiled the ground. Its immense size has dwarfed them into a mere bit of pleasure ground attached to it; while the wretched condition of the Portugal Laurels, and some of the Conifers, clearly seems to tell the tale that nothing but deciduous things can be relied upon, and when we get the great steam engine at work, and all the machinery for the refreshment department moving, what the result of such an invasion of the blacks will be it is not difficult to foresee.

The number of subjects sent in was not large, and mainly consisted of Orchids and foliaged plants. A pale variety of *Cattleya Trianaei* was exhibited, but was not considered worthy of any special notice, although a finely-grown plant.

Two plants of the fine variegated *Phalaenopsis Schilleriana*, from Manilla, were exhibited by Mr. McMorland, of Haverstock Hill, and Mr. Warner. It was unanimously adjudged a First-class Certificate (it had been previously shown as a small plant by Mr. Bull, of Chelsea). The leaf is larger than amabilis, of a dark olive green, and dull whitish markings on it. The flower is of a white colour, with rose pink markings. Altogether one of the finest things in Orchids introduced for some time.

Mr. Vetch sent a plant of *Lælia elegans*, from St. Martha's, and a collection of *Lycastes*, showing the great variety of marking which they exhibit.

Mr. John Standish, of Bagshot, sent (in a weak state) a new Lily from Japan. The colour of the flowers is a pale straw colour, with dark chocolate-coloured spots, reflexed in the way of the Martagon Lilies. It was considered not to be sufficiently good condition to warrant notice, but will, doubtless, be brought forward again. It will be hardy, and should be grown out of doors in some good, deep peat, when I think it will prove to be an acquisition.

From Mr. Bull came a fine Fern, called *Cibotium princeps*, with magnificent fronds. It was awarded a First-class Certificate. Also *Oreopanax dactylofolium*, a fine-foliaged plant, which received a Label of Commendation. Also, *Rhopala crenata*,

Anthanium acule, and some semi-double white Primroses, the latter having come true from seed.

An interesting discussion arose as to the omission of certain florists' flowers from the schedule, of which one may have to say something next week, perhaps. Very strong feeling was manifested as to the injustice of the omission.

HERBACEOUS PERENNIAL FLOWERS.

THIS class of plants is now often inquired about. Many ladies, and gentlemen too, are desirous of growing them extensively, in order to avoid the trouble and expense necessarily involved in the bedding-out system. Where the family is at home all the year round, great expense must be incurred to keep the beds and borders furnished with plants if the bedding-out system is fully carried out, or else the beds will be bare and, of course, unightly from November to June; whereas, a border of herbaceous plants, after the first expense, is easily and cheaply managed, and is always interesting throughout the whole year. Without entering into the merits or demerits of the old system of, as London calls it, the mingled flower garden, or the more recent and fashionable mode of furnishing a flower garden in masses of half-hardy plants, permit me to offer a few remarks on the old-fashioned border flowers, except herbaceous perennials, which, if well grown and properly arranged, will always have a goodly display of flowers from February to November. Such a border is suitable for gardens of all sizes, from the cottage to the palace. In such a border the object would be to select kinds that produce abundance of flowers, last a considerable time in bloom, possess attractive colours, and that are hardy enough to bear the variations of our climate without much trouble in protecting them from the effects of frost. Many years ago I formed and arranged such a mingled flower-border, which gave great satisfaction to my employers, and was much admired by every one that saw it—especially such visitors as were in the habit of seeing the place during the whole season. I had not so many species to work with then as there are now in cultivation; hence the cultivator of the present day has the means of far surpassing the border that I planted then.

By herbaceous perennial I mean such as are neither biennials nor annuals, nor yet such as are designated florists' flowers. Hardly bulbous species, to some extent, I would admit into my selection or pattern.

In large places, even where the bedding-out system is fully carried out, a border of herbaceous perennials, such as I shall describe presently, might be found a place for, just as in such gardens they have separate situations for a rosety, an American garden, or an aquarium of hardy flowering aquatic plants. In gardens of smaller extent this flower-border might form a principal feature backed with evergreen and flowering shrubs; and in villi and cottage gardens it would be all-in-all.

In most gardens the herbaceous flower-border is such a mingled irregular mass of subjects that it very rarely presents an agreeable appearance. Sometimes there is a fair show of flowers here and there, but the mixture is so incongruous that the eye of taste turns away from it—I would not say in disgust, but certainly dissatisfied. The reason is that there is an absence of order and regularity. It is a confused assemblage of objects which, however beautiful individually, are so jumbled together that the effect is spoiled as a whole. That state of herbaceous borders held, no doubt, in a great measure to the adoption of the massing system, which, at certain seasons of the year is exceedingly showy and effective.

These faults in arranging the mingled flower garden I shall now endeavour to correct by first giving a routine of management, which consists in preparing one border, planting and transplanting, stirring the soil, manuring, keeping the plants neatly tied to supports, thinning the shoots, watering, cutting down when done flowering, propagation, and lastly, arrangement, which includes a select list of the best kinds to produce the best effect. Under each of these heads I shall briefly but sufficiently describe what I consider the best modes of carrying them out in practice.

PREPARING THE BORDER.—This may be of any length the owner chooses. It may be bounded by a hedge of Roses or Sweet Briar, or even by an espalier hedge of fruit trees, or by a shrubbery. A walk of any convenient width may run down the centre; thus there will be a border of flowers on each side. The width of each border should be 7 feet, which space will hold four rows of plants. The first row at the back will be

2 feet from the boundary; the second row, 2 feet from the first; the third row, 1½ foot from the second; and the fourth or front row, 1 foot from the third and half a foot from the edging of the walk. The objection to a wider border is that the row of flowers at the back is too far off the eye to be seen well; and the objection to a narrower border is that the tall-growing species will overshadow the dwarfs in front. The first thing to do, after setting out the borders and the walk, is to form the latter, cutting a deep drain down the centre, and laying cross-drains across each border into it; then make the walk in the usual way; and, after that, trench the border as deep as the soil will allow, adding to it a good dressing of leaf mould, very rotten dung, and sandy peat, in equal quantities. If sandy peat is inaccessible then use as much river or pit sand that has no iron in it; mix this dressing well with the soil, and the borders are ready for planting.

PLANTING AND TRANSPLANTING.—I use both terms advisedly, for a reason that I shall give by-and-by. The best season for planting the herbaceous-plant-border is March; but for bulbs, the time I always adopted was October, more especially for the Lily tribe. If possible, strong plants of all the species should be planted, in order to have a good fair bloom the first year, though I always found the second year's bloom more abundant and finer in quality. It will sometimes happen that some of the plants will not thrive well; hence it is a good plan to have a reserve garden in some retired nook or corner; and there I would keep several plants of such species as are either tender, or from some other cause likely to fail in the garden. If these are kept in moderate-sized pots, then, whenever a vacancy occurs that vacancy could easily and quite safely be filled up from the reserves. Some species, however, do not thrive in pots—such should be planted out in reserve-beds, and transplanted with a hollow spade, or tool as the navvies term it. The trans-planting would be performed even better and more safely by two men each having one of these hollow tools. The object is to move them with as much soil adhering to the roots as possible. Have the holes ready made and drop the ball gently into them, filling-up with the soil removed, and then give a good watering. With this care in transplanting the plants would scarcely feel the removal.

The Distances in the Rows.—The plants in the two back rows being in general strong growers, I plant them 3 feet apart in the row, placing the second alternate with the first. The third row being both less in height and generally in width, I allow 2 feet between each; and the fourth or front row being still less, I foot between them is sufficient. When all are planted the soil should be forked over, broken fine, and so left. By no means rake it, for that makes the surface too fine, and the soil is then liable to become cakey on the surface and often cracks when dry weather comes, letting out moisture and admitting drought to the roots.

STIRRING THE SOIL.—During the summer the Dutch hoe should be very often used—not only to destroy weeds, but also to keep the surface loose and friable, and should it ever become hard then give it a shallow forking over with a five-pronged fork for the back row, and a three-pronged fork for the front rows. This frequent stirring of the soil is highly advantageous to the plants, besides giving a freshness and neat appearance to the borders. Yet how seldom is it done! In most places a mere shallow hoeing to cut up the weeds, and then a raking to clear them off, is all the treatment nine-tenths of the herbaceous borders receive.

Yet if Potatoes, Cabbages, Turnips, and other vegetables are benefited by deep hoeing or forking, surely flowers will enjoy and be benefited by such operations equally as well.

T. APPELEY.

(To be continued.)

SKERRY BLUE POTATOES.—Skerry Blue Potatoes receive their name from a mountain in the neighbourhood of Ballymena. A farmer in its vicinity found a few Potatoes in a barrel of Riga flax-seed; these were planted, and now their produce is known as the Skerry Blue Potato. In the district of their original Irish home they are, I think, more extensively cultivated than, perhaps, any other two sorts. I have grown them for five or six years, and always found them proof against the disease, good croppers, and, when well kept, excellent for table. They are naturally of a small size, and inexperienced cultivators are liable to err in planting too close; they should have 15 inches in drill and 30 inches between drills. By attending to this, and giving

them the usual working, I have had, under ordinary circumstances, a good crop of sound-eating Potatoes.—C. C., Belfast. — (*Irish Farmer's Gazette*.)

TANK IN A GREENHOUSE.

I HAVE a greenhouse some 20 feet by 15 feet, heated by hot water and a flue. The fire-place is at the back, the flue running along the back, with a chimney in the corner. The water-pipe runs along one side and the front, then turns into a stone propagating-tank, and so the water goes back again into the boiler. I had this tank for the purpose of propagating cuttings, which I must say succeeded admirably. However, my gardener complains that the plants in the house lose their foliage, and are apt to damp and mildew. He says it is entirely owing to the tank, which being of stone, and porous, allows the damp to exude, and he is very anxious to do away with it and the propagating-bed altogether, putting an iron return-pipe in its place. This I am very loth to do, as the convenience and use of the propagating-bed are very great. Will you advise me in the dilemma?—ROBERTSON.

[Is your tank securely covered to prevent the damp rising that way? If so, then the porosity of the sides might be neutralised by painting it with thick paint when dry. We should be more apt to attribute the damping and mildew to a low temperature and a deficiency of air. We think the pipe and the flue ought to do more than neutralise what vapour might escape from the tank. However, if you please the gardener by having a close return-pipe, you may take that through your tank, and instead of water fill it with rubble, such as stones, &c., above the pipe, and then with sand, &c., and you will have your propagating-bed just as before. If the arrangement of the house permitted, you might also have a propagating-bed round and over the flue near the furnace. It strikes us, however, more ventilation, and a little more heat in consequence, would satisfy all parties. You may keep a moist atmosphere about the cuttings by covering them with glasses.]

NEW PINE APPLE.

The new Pine called, from the province in Brazil where it is found, Abacoches, has been sent to Baby Castle, and is one of the greatest acquisitions to this class of fruits.

The fruit is a perfect cone, the pips large, their colour at the base deep crimson shaded off to dark orange; the flesh is deep yellow, very juicy, and tender, and in flavour cannot be surpassed. It is a dwarf grower, and possesses the good property of keeping some time after being cut. Those who have had an opportunity of seeing the fruit pronounce it first-class. Average weight 6 lbs. to 8 lbs.—ENOR.

THE CULTIVATION OF POTATOES AND OTHER CROPS.

"My Potatoes are rotted as well as other people's, and I don't see why you should be favoured more than the rest of us." "Well, Mr. G—, in order to convince you, come and see mine." "No, I won't, or be convinced either!"

Thus ended a palaver with a neighbour some nine years ago, and, of course, no more could be said; but if the gentleman had remained to be my neighbour up to last year (and so far as the Potato disease in gardens was concerned I never knew a worse one), the result and the observations would doubtless have been the same. I did secure a very good crop last year; and as I am now about preparing for planting again, it may not prove unwelcome to many if I give my method of proceeding in detail.

I made known long ago in the old series that I keep my seed in a cellar averaging 40° to 50°, in a subdued light, and spread out singly in layers on wooden trays from the day that I take them up till I want to plant them, when they will have become furnished with stout sturdy shoots firmly attached. When I plant, at each end of a row opposite to the sets I drive down a substantial piece of stick to remain there till the following year, in order to point out that the tubers of next year shall not occupy the site of this. I never use raw manure. Quicklime or mortar rubbish, which is spread over the surface soil, and

slightly worked in just before planting at the beginning of March, is what I prefer.

For early Potatoes I allow 36 inches between the rows, and for store Potatoes 42 inches quite. Strain a line from two pegs where the rows are to be, and place the sets upon the surface of the soil, at 1 foot distance for the earlies and 15 inches at least for the late sorts. I always use middling-sized whole sets. Then readjust the line to the full width of the spade, and mark out for a trench centrally between the two rows of Potatoes. Cut down in order to leave the sides even, and cast out every other spadeful right and left, though not exactly plump on to the shoots of the sets. The crumbs that are afterwards shovelled out take that central position harmoniously; and we then have a trench formed nearly a good spit deep, which is intended to become occupied with the Cabbage tribe anon. Formerly, as each trench was finished I used to introduce raw dung, and dig that into the bottom; but now I merely dig the bottoms of the trenches, as, having a large supply of liquid manure (house-sewage), I use it bountifully just as when the plants have attained to good size. I use McDougall's, of Manchester, patent disinfecting powder as a deodoriser, and otherwise than for this purpose it is a good and effectual remedy. In digging out the trenches for the early Potatoes I do not make the spade bite quite so deeply as for the later varieties, and I prefer the Cauliflower and Grange's Broccoli to take their stations between the former.

Eleven years ago, when I first began to feel my way on this ridge-and-trench plan, poor old Brotherton declared that I "was going to grow Potatoes upon raised banks sufficient for a Norman encampment." But he was an old soldier, and, I fear me, sometimes shot with a rather long bow. This is the sixth or seventh year since I adopted the plan *in toto*, and I continue to recommend it for the following reasons:—In this garden, which is overlooked by part of the living-room windows, I like to see everything shipshape, albeit the rector does say that "constant experiment makes a place look untidy." But raw dung hauled about a space of ground after the Potatoes are taken up, and then followed by the planting out of lanky Broccoli plants, &c., is never pleasant in a small garden in the height of summer, nasal or otherwise; and under the most favoured circumstances the plants will take a month or six weeks to recover themselves and to look decent. But by the trench rule they can be planted out expeditiously at their proper stage of growth without being kept waiting for the Potatoes to come off, and seldom inclining to club in the trenches; and we had Kale and Broccoli last year when none of their kindred were to be found in the neighbourhood. Again, how seldom do we find the moulding-up of Potatoes done properly, or at the proper nick of time? In the above system that practice is quite superseded, for from the moment they are planted till they are lifted nothing in that way is required; by reason that quite sufficient soil is cast upon them in the first instance, which also insures their non-appearance aboveground till the first or second week in May, when danger from frosts is over, and we may fairly anticipate their ripening to have become accelerated a fortnight at least.

I have read with great interest the communications in THE JOURNAL OF HORTICULTURE apropos to the earthing-over-head-and-cars system as a preventive of disease, and if I could afford the space I would adopt the plan for a trial. I formerly allowed the haulm of mine to fall down on each side the ridge, but I found that with the later sorts especially, they interfered with and muddled up the occupants of the trenches; so to obviate this I now drive stoutish stakes on each side of the ridges 5 yards or 6 yards apart, and strain a line of tar cord to them to retain the haulm in an upright position, and once or twice I clip off with the garden-shears the overhanging points, should they become too long and dense, so as to exclude the light and air from the Cabbageworts below. The clippings I clear away in a basket, when I take this opportunity to catch and kill the caterpillars from off the Cabbage tribe—a very necessary procedure.

As to the Potato disease, it is sure to come, and the later the better; but sooner or later, and just one week after I have observed the first spot, I take up the crop. Every Potato in this garden was carefully lifted, and under my inspection, by the last week of last July. Their skins were certainly very tender, but they soon toughen when placed not too thickly together. Had I allowed them to remain in the ground a week longer I should inevitably have lost the crop; as it was, all I had to

regret in consequence of the earliness of the blight was their size. And to prove that that was not so despicable, and that others need never fear to lift their Potatoes, provided they do so carefully when their skins are far from set, I submit some for your judgment. They are the Lapstone Kidneys (white), and the Haigh's Kidney (mottled red), though I never knew which was which. They were presented to me some years ago by Mr. Cleall, gardener to Sir Frayton Drake, Bart., Lympstone, Devon, amongst other sorts, and I managed to confuse the names.

The white Potato, if it is the "Lapstone," is what I consider the acme of perfection as to what a Potato ought to be, and the mottled red one, if it is the "Haigh," is not so good a cropper, and more likely to take disease; but it is the most apt flying, the richest Potato, so to speak, I ever partook of. Those of the darker hue are the same sorts which were taken up last August twelvemonth. I do not allow my store Potatoes to become deteriorated from "sprouting;" they are made to pass through the hands to detach all and every shoot ere it exceeds the eighth of an inch.

But, to revert for a minute to the ridge and trench. When a dry season arrives the tubers have got a larger bulk of soil to grow in. Should a wet season occur, the water drains well away into the trenches, and nearly a double surface of earth is gained for the beneficial influence of atmospheric action, and when the Potatoes are lifted a quantum of soil falls down, and creates a first moulding for the Cabbageworts, which appear a healthy and flourishing crop upon the ground at once. It is astonishing the produce that can be got from a small garden under this system.

The following are the names of the Cabbageworts I grew in the trenches last year. Commend me to them. Cauliflowers in June, followed by Walcheren Broccoli till October, succeeded immediately by Snow's Winter White Broccoli (much sooner than those mentioned by Mr. Fish in his "Doings of the Week"), and coming in successively till the 25th of January, when I cut the last dish. Every plant gave me a head, and such heads some of them were, good gracious! I have had since November, and have now, the Roseberry Brussels Sprouts very fine. I have the Incomparable and the Frogmore Protecting Broccoli very promising to come. Have had all through the summer, autumn, and winter, and have coming in for spring, Mr. Turner's Eclipse Cabbage, which has proved with me a first-rate sort. I have a sweepstakes going on with it and a kind from Jersey. I have had Dwarf-curl'd Savoy, Galore, and shall have curled Scotch Kale to the end of the chapter. The Aytton Castle Leeks have proved large and excellent for trench-work. I have still a good supply, with Seymour's Red Celery, and the new White Strap-leaf Turnip is a good sort, it has stood with me through the winter, but is now become as warty as a drunkard's nose.—UPWARDS AND ONWARDS.

[The Potatoes were a full average size and well kept. The Shutford Seedlings were just beginning to sprout. Mitchell's Albion Kidney (the best of the earlies), Haigh's and the Lapstone Kidneys had not at all vegetated, nor had the two-year-old specimens. The Celery and Leeks set were above an average size, and of first-rate quality.—EDS.]

FRUIT AND FLOWERS IN THE SAME HOUSE.

ALTHOUGH I feel but little right to occupy your better-filled pages, yet with your permission I will give a little sketch of my gardening success as an encouragement to those who, like myself, have few appliances and little skill. I am so deeply indebted to the healthy exercise and interesting employment of horticulture—I feel so convinced of its benefit both to mind and body, that with so favourable an opportunity of advertising my favourite panacea for diseases of both, I should consider myself culpable in not profiting by it. More especially would I endeavour to encourage amateur gardeners who are thrown chiefly on their own resources; for such, I feel, have a keener relish for the art than any other person, since the pursuit is their own choice, and they have many difficulties to contend with that nothing but real lore for it could surmount. To such, then, I particularly address myself, premising that I have no regular gardener, and that I take the whole superintendence of my plants on myself.

In 1837, principally to be enabled to add a little decoration

to a local cottage garden society in which I was interested, I built a small greenhouse, 18 feet by 12 feet; it is a lean-to, facing the south, lofty, airy, very well built, and heated by flues. The inside is fitted up on a plan of my own, calculated to display the flowers in their several seasons, as my aim is to get a succession of well-accredited species rather than a greater variety, and never to attempt growing such as are not suited to the temperature of the house.

At the expense of a few pounds, and a *carte blanche* on two or three friends' houses, I soon had a gay stand which, with perhaps an annual interregnum of a few weeks, has continued so ever since, allowing a little overplus for my drawing-room windows.

Thus much for the Ornamental. I now come to the Fruitful. I bought a Muscadine and Black Prince Vine, a Sweetwater from my own vinery (where in fine summers they produce excellent Grapes), and a Black Hamburg, a far-off descendant of the famed Hampton Court Vine, from a neighbour. Here I had the good offices of my occasional gardener, who works two days a-week for me. He cut back the Vines for three years, and then only allowed a few bunches; but last year we had a superb show—at least 50 lbs. of well-ripened Grapes, of fair-sized bunches, large berries and high flavour. They appeared at many of my friends' desserts, and on one occasion without, I am told, losing by the comparison, side by side with some for which 4s. a-pound had been given, from the vinery of a noble proprietor.

Have I said enough to prove my position, that good fruit and fine flowers may, by a little management, be made to ripen and bloom together in the same house, and that a small one?

My statement is a very plain one; but I hope the results it announces will induce others to try the experiment, who will soon oust me in the race, and will, I trust, give your readers the benefit of their success.—A. Z.

STATICE HOLFORDI—MONOCHÆTUM ENSIFERUM DAMPING OFF.

RHIPSALIS SALICORNIOIDES CULTURE.

I HAVE under my care some plants of *Statice Holfordi* which were struck and grown in the stove early last spring; when showing for bloom they were removed to a cool house, and when in bloom were taken to the conservatory, with the exception of one, which soon showed symptoms of bad health, the bloom-stalks dying off before the flowers were expanded; and on examining it I found there was a kind of humouric matter in the heart of the shoots, which, in time, rotted them, and the plant has kept breaking afresh and dying in the same way till it has nearly lost its foliage. The others flowered well; but since they have been back in the stove one has become nearly as bad; meanwhile, an old plant that has had the same treatment is in good health.

Also two plants of *Monochætum ensiferum*, which have had greenhouse treatment during the summer, but have kept dying back till one has died outright, and the other has died to a stump, and I cannot account for it as I have watered them carefully, &c.—J. W.

[We cannot be sure what is the matter with the *Statices*, except changing the temperature too suddenly, and using compost rather heavy. Try what the least thing of salt in the water would do—say one-quarter of an ounce to the gallon.

The *Monochætum* should not often be below 45° in winter. Sandy fibry loam, and a little leath mould will grow it well. We cannot account for your plant dying back, as, unless in winter, it seems as easily grown as a *Fuchsia*.

The plant you enclosed is *Rhispalis salicornioides*, requiring to be grown in sandy heath soil, with a little loam, and to be kept in a temperature of from 50° to 60° in winter, and from 70° to 85° in summer.]

SEAWEED AS A MANURE.

HAVING lived for years on the southern coast, I am, of course, aware that seaweed is extensively employed as a fertiliser by professional and other tillers of the ground. This much I know, but more than this I wish to know. I desire to be told by some enlightened horticulturist, how, when, and for what it should be used. Ought it to be applied to the land in the crude

condition in which it is carted from the beach? or should it be gathered into a heap and suffered so to remain until decay has wrought a conversion? Is it suitable manure for culinary crops generally? I am told that when put together in a heap the process of decomposition is a tardy one. Of this fact I have some evidence in a fisherman's seaweed-but some half mile hence. If mixed with the refuse of terrestrial vegetation, would decay ensue more quickly? Prejudice has hitherto hindered me from proving these things by experiment.—R. MULLEN.

[General experience has long since proved that seaweed cannot be dug or ploughed into the land too fresh, and if immediately before sowing or planting the crop all the better. It is quite true that in the Isle of Thanet they mix the seaweed with earth or sand in alternate layers, and let it decompose before using it as a manure; but the general experience in other parts of England, Scotland, Ireland, and the Channel Islands, is in favour of using the seaweed in its fresh state. There is no kitchen-garden crop for which it may not be used advantageously. For Beet, Parsnips, and Carrots, at the time of trenching the seaweed should be dug in with the lowest spit. Seaweed is an excellent covering for Asparagus and Sea-kale-beds in autumn, and is an excellent mulch for all freshly-planted trees.]

GOURDS AND THEIR CULTURE.

THE Royal Horticultural Society having offered prizes for this class of fruits, a few notes on their culture and general features may be of service to the inexperienced cultivator at a time when this hitherto-neglected family seems likely to be brought into public notice, and the individual members of it subjected to a rigid scrutiny, with becoming honours paid to those to whom honour is supposed to be due. It will be as well to call to memory the varieties which from time to time have been popular amongst us, with the mode of culture, and other particulars relating thereto.

The extensive families of Gourds, Pumpkins, and Vegetable Marrow seem so much united by intervening links of connection that it is no easy matter to define them; and the class of Snake Cucumbers is also allied to this family. Some years ago one of the Cucumber Gourds was exhibited at one of the London shows, upwards of 6 feet long, and I believe this has been much exceeded. But the largest and finest specimens, doubtless, have the advantage of glass, which is certainly not advisable in a general way; and as a varied and interesting group can be obtained without further aid from glass than rearing the young plants in it for a short time in the spring, only such kinds will be here treated of as will bear planting out of doors at the end of May; and for that purpose they need not be sown until about the end of March or first week in April, if there be a hotbed, pricking the plants out in pairs into six-inch pots, and after being grown awhile in the same hotbed, they may be gradually hardened off, so that at the time I speak of they may be finally planted out of doors. Plants a little pot-bound are no worse, provided they are healthy; but do not allow them to root through the bottoms of the pots into the bed or place they are standing on, which they are very apt to do, and consequently to suffer when removed to their permanent quarters. Keep a watchful eye on green fly and other enemies, and if any appear let the plants be fumigated with tobacco before planting out, as it is difficult to do afterwards.

Situation—It is rarely that this class of plants is much favoured that way; but an open sunny place is necessary. Planted on the top of a bank they will specify cover it; and sometimes they are planted to cover old roots, the face of rockwork, or to scramble over a rubbish-heap, or amongst dry dead sticks, against palisading, occasionally against walls, and over roofs of all kinds, and sometimes to cover verandahs, arches, grottoes, and other descriptions of toney work, all of which the hardy kinds are adapted to do in favourable seasons, and they accomplish it all with less trouble than most plants require: for, excepting the fastening to palisading, walls, arches, &c., the other positions require little or no attention whatever. Some of the delicate kinds may, however, require a snug corner against a wall, and some training and stopping will enable the plant to bear and perfect its fruit.

Soil.—The ordinary garden soil will do. Certainly they do not require a rich loamy soil. A light stony one, not by any means shallow, suits them best: for if the roots be denied the sustenance they want, mildew attacks the plant at once, and its

usefulness is soon over. On the other hand, a too generous soil induces rankness of growth, which is inimical to bearing fruit in any quantity. Ordinary well-cultivated garden soil generally, however, answers very well; and, as I have before observed, the rubbish-heap, consisting of stones and other garden refuse, is a capital place to grow them on, if it be a sunny one. Last year I had several rustic arches made to cross a central walk in the kitchen garden, and Gourds were planted against them, and in general they did very well. The growth after the 1st of August was more rapid than before, July being a dull month here. Their culture is, the more, an easy matter, merely tying them up to the supports, and occasionally cutting out shoots not wanted.

Varieties.—As regards the eatable kinds, there is much difference of opinion. Mr. Curtis introduced a variety, some years ago, reported to possess good properties this way, but it quickly fell into disrepute, and from time to time we have had what were said to be improvements on the old Vegetable Marrow. Three or four years ago the Custard Marrow was in great repute, but it lost many friends last year, and I believe the old Vegetable Marrow is still the premier in its class; but there may be other varieties having local reputation, which the forthcoming Show will, doubtless, bring out. Varieties of extraordinary size are plentiful enough—at least, seed lists report them to be so. As I confess, I have only grown one variety of this class, and it was too late to attain maturity; but well-recommended varieties may in a general way be depended on. This class requires a great deal of room, so that few growers can find space for many kinds. Varieties for appearance are, perhaps, the most numerous of all, and may be subdivided into several sections, which I find is done in the admirable collection mentioned in Messrs. Barr & Sugden's catalogue; there is no difficulty, therefore, in obtaining a collection. There is great diversity in the habit and character of this fruit: the miniature Gourds are not larger than a hen's egg, while the mammoth varieties are sometimes grown considerably over 100 lbs. in weight, and instances have been known of their being nearly double that weight. The most beautiful, however, that I have seen are the intermediate sizes, something about the stamp of an ordinary Melon; while the Bottle Gourd, Hercules' Club, Snake Gourd, and others are all interesting, and all manner of stripes and streaks. One of the most ornamental kinds grown here last year was a Pear-shaped one, the thick or lower end being green, while the other end was a clear yellow, and there was a clearly-defined line where the two colors met—not the least running of colour could be discerned. The old Orange-striped Gourd has been greatly multiplied, and I green-and-white-striped varieties of several kinds abound. One of the prettiest of this class I saw last year at Bolton, the seat of Earl Browning, in Lincolnshire, and I believe the same was at Sir John Eborchold's, in the same county. But as many new varieties are, doubtless, only now waiting to be distributed, the autumn of 1862 will exhibit a great increase in collections of this kind; and if the exhibition serves no other purpose, it will at least enable us to weed out the useless and indifferent from those of an opposite description. But I do not by any means advise the amateur to try to grow too many of them; the space they occupy cannot always be spared in grounds of limited extent, and unless they have room they are worse than useless. A sunny aspect is also requisite; but the more they are sheltered from winds the better, as in very exposed places it is useless to expect them against pillars and similar windy places, but on the ground they may do better.—J. ROBSON.

COLUMBINES.

The Columbine (*Aquilegia*) a few years since was more common in our gardens than we see it at present, yet it is now a beautiful ornament of our cottage homes, where some of the best varieties may still be found. I well remember an old-fashioned garden where a few of the best varieties were cultivated and cared for as we rarely see them now; but I am grieved to learn that the stock is destroyed, and the ground used for building upon.

The beautiful *Aquilegia glandulosa* is becoming very rare in our gardens. I must confess that I never could grow it to perfection, as I am informed that the gardener who can grow it to perfection in England is a rare sight to see. I have grown plants from seed, and had plants sent from Forres, N.B.—where it grows like a weed in so many gardens, and in others it flourishes a short time, and then gradually dies away—yet with all my

care and attention I never could get a plant to grow and flower well.

One of the market-women, who attend the market at Sheffield to sell hardy plants, used to offer for sale during the flowering season well-grown plants of *A. glandulosa*. Knowing that such well-grown healthy plants as she offered for sale were rarely seen, I inquired the means by which such results were obtained. Her reply was, "Nothing is more easy. We grow them in common garden soil, mixed with sandy peat from a neighbouring common, and we have no further trouble with them; and I can assure you that the money which we obtain by the sale of the plants will nearly pay the rent of our garden." Has any reader of THE JOURNAL OF HORTICULTURE tried this plan; and if so, what has been the result?—RUSTIC ROBIN.

NEW AND RARE PLANTS.

CERODENDRON CALAMITOSUM (*Heartful Cerodendron*).

Nat. ord., Verb-naceæ. *Lin.*, Didymia Angiosperma.—Native of Java. Its white flowers are very unobtrusive compared with those of some other species cultivated in our stores.—(*Botanical Magazine*, t. 5291.)

ARISTOLOCHIA ARBOREA (*Tree Aristolochia*).

Nat. ord., Aristolochiææ. *Lin.*, Gynandria Hexandria.—Native of New Granada. Each of its very peculiar tubular brown flowers is closed by a velvety disk. They issue from the stem near the ground. The stem is about 7 feet high.—(*Ibid.*, t. 5295.)

MAXILLARIA VENUSTA (*Graceful Maxillaria*).

Nat. ord., Orchidææ. *Lin.*, Gynandria Monandria. Probably identical with *M. anatumorata*.—Native of Ocaña, in New Granada, at an elevation of 5—6000 feet above the sea. Flowers white, with two round crimson spots on the lip. Blooms in October.—(*Ibid.*, t. 5296.)

CROCUS OCHROLEUCUS (*Cream-coloured Crocus*).

Nat. ord., Iridææ. *Lin.*, Triandria Trigynia.—Found by M. Gaillardot in a clayey soil near Scanderon on Mount Libanus. It is found blooming there from October to December. Flowers creamy white, with a yellow eye.—*Ibid.*, t. 5297.)

IRIS LONGIPETALA (*Long-petaled Iris*).

Nat. ord., Iridææ. *Lin.*, Triandria Trigynia.—Native of California. "It seems quite hardy, and will prove a great ornament to our flower garden." Flowers purple, and white striped with purple.—(*Ibid.*, t. 5298.)

LEEA COCCINEA (*Scarlet-flowered Leea*).

Nat. ord., Ampelidææ. *Lin.*, Monadelphia Pentandria.—It has also been called *L. lucida*. Most erroneously, in gardens it has been named *Panax exelsa* and *Aralia exelsa*. It is held to be a native of Java. "Deserves a place in our stores on account of its graceful habit, and its thickly-flowered cymes of scarlet flowers." Plants begin to bear flowers when less than a foot high.—(*Ibid.*, t. 5299.)

THE GARDENS OF DAMASCUS.

BEAUFORT'S "Eastern Shrines" gives the following interesting description of the environs of Damascus:—

"A new ride can be taken every day for four months among the charming groves, fields, and orchards, with pleasant-looking villages here and there, about the city of Damascus. A network of little canals and channels of water extends over the cultivated plain, cooling the air, and soothing the ear with the pleasant murmuring of the streamlets to which all the glorious verdure is owing. Miles and miles of these tiny rivers are spread over the ground, every one coming originally from Barada—the Abana of Scripture, which Nauma considered with natural pride as fine a river as any in Israel. The Pharpar, or, as it is now called, the Awag, is not so long as the Barada, contains scarcely a third as much water. It rises on Mount Hermon, and both rivers after passing Damascus are lost in the marshes on the sandy desert beyond. There are many varieties of trees in the gardens of Damascus; but the most numerous are the Apricots, the dried fruit of which forms so very large a part of its commerce. The Apricots are either dried in the sun, and

then pressed in slight wooden boxes, or else they are stoned and mashed into a thick paste, which is dried in masses a yard or two long, and is exported in large rolls, looking like brown leather. It is said to be a lovely sight to look over the plains in Damascus in the spring, when the innumerable Apricots are in flower—the effect being of light snow resting on the trees; but many persons think it more striking when the fruit is just ripe—then the trees glow as if illuminated with thousands of tiny lamps hung among the branches. One of the pleasantest afternoon rides was to the village of Jobah, at about an hour's distance from the city, where it lies hidden among Walnut-groves. This place has been, time out of mind, held sacred by both the Jew and the Moslem; and there is a very ancient synagogue built over the cave in which it is believed that Elijah hid himself from the persecutors of Jezebel. In the centre of the synagogue there is a space railed off, where Elijah is said to have anointed Hazael king."

SOWING CATTLE CABBAGES.

I PURPOSE practising Mr. W. Johnson's plan of sowing the seeds of the Drumhead, and other Cabbages, but would have been glad to have been told at the same time the proper time for sowing the former sort, so as to have a good winter supply. The writer has years ago pursued this plan with his garden Turnips, and particularly with Asparagus, which he has found produce excellent beds much quicker and finer than by plants. He has found two-row beds the finest and easiest managed. The writer has years ago had very large heads of the Drumhead Cabbage in winter in another county, but has quite forgotten when he sowed the seed. Soil sandy loam, north aspect.—A PEBBLING GARDENER, *Norfolk*.

FLORISTS' FLOWERS,

THEIR DISTINGUISHING CHARACTERISTICS, CULTIVATION, AND VARIETIES.—No. 2.

THE CAMELLIA.

THERE is not, probably, within the wide range of Flora's dominions so universal a favourite as a double white Camellia. It lacks, indeed, perfume; but who ever met any of the gentler sex, the truest and best lovers of flowers, who did not exclaim, when looking on the snowy petals of one of this lovely tribe, "How beautiful!" And what loveliest Corydon has not felt that there is not one he could be so sure of being acceptable to his Phyllis as one of its half-expanded buds, or even a full-blown flower? But to every loyal subject it has now a deeper and more solemn interest, for it formed the centre of the bouquet which our Royal Mistress sent, as her last touching tribute of real love, to be laid on the coffin that contained all that was mortal of One who had been to her more than all the world beside. There are many who will never look on a white Camellia again without recalling the memories of an affection which is indeed rare in king's palaces, and which God honours wherever it exists.

We hardly can wonder at this admiration. The snowy whiteness and thick solid character of the petals, combined with the rich glossy foliage, form a picture of great beauty; while the glowing colours of the rose and crimson varieties are nearly equally attractive—and their cultivation is really so easy that there can be no reason why they should not be universally grown. There is but one period of their growth wherein they present any difficulty, and that I shall notice by-and-by; although I feel somewhat of a perplexity in writing about them, as so much has been said, and said so well, by Mr. Anderson in some late Numbers of the JOURNAL OF HORTICULTURE.

Notwithstanding the exceeding beauty of the Camellia in general, there are some kinds which are considered to surpass their congeners in the matter of form; for it now has been brought within the range of florists' flowers, and subjected to the arbitrary rules which govern that portion of Flora's realm. The model idea of a perfect flower is here given to the reader, and it will be seen from it that the petals ought to be round, smooth on the edges, and gradually decreasing in size from the large outer guard petals to those which form the centre or crown of the flower; viewed at from the side, it ought to rise regularly in a semicircular form. The convexity with which this

laying of petal over petal is present in some varieties has led to their being called "imbricated." Probably as perfect examples as we have are Montaroni (white), and Master Rosa (rose). The latter are almost if not altogether unknown varieties in England, but to which I have referred in a notice lately given on Monsieur Cachet's nursery at Angers. As to habit, it is extremely desirable to avoid all that loose straggling method of growing to which some kinds seem unfortunately wedded; but avoid by all means that old fallacy that the knife is death to a Camellia. On the contrary, as Mr. Anderson has well observed (and indeed his papers almost preclude my saying anything on the point of cultivation), in your Journal, p. 393, there is no plant that so well stands pruning as the stronger varieties of the tribe. I believe the idea arose mainly from the dislike to cut off a dainty-looking bud and its attendant leaves; but in gardening, utility must give way to sentiment, and a plant of Camellia may be as easily trimmed as any of the order to which it belongs.

The very extended and minute directions given by the writer above named are perhaps intended rather for extensive growers; while mine are more adapted for those who, with their small greenhouse such as is described in the Journal of February 11th, wish to have a few of these universal favourites, and perhaps to bring them into the sitting-room to bloom. With such propagation has no place, and indeed is, I believe, rarely practised except by those who grow for sale. The process of grating is tedious and requires heat, and, when plants can be purchased for a couple of shillings, does not pay. There is no soil preferable for growing them in to one of peat and loam, with some pieces of charcoal broken up in it; and if due care and attention be given to them, I question whether shifting every year is desirable. I, too, know plants which seem to me never to get one. There they are in the window of a neighbour, with leaves looking as glossy and bright as possible—I have no doubt carefully cleared at times, and amply repaying the care by their vigour and beauty.

I should say that with regard to the best period for potting there is some difference of opinion amongst gardeners; some doing it immediately after blooming, others waiting until the growth is made.

When the plants have done blooming and their fresh growth commences, is the time that those who grow only a few and have no warm house are apt to fail most. At that period the plant likes heat and a damp and close atmosphere. Where this is not procurable the next best plan is to put them into a frame, shading the portion where the plants are, and syringing frequently; but as this must be done when all fear of frost is over,

it will of necessity make the plants to come into bloom later. After they have completed their growth they should be first hardened-off, and then stood out of doors in the shade. Here oftentimes they receive much injury from the intrusion of worms into the pots, and should therefore be placed on tiles or slates to prevent this. Should the weather be dry, of necessity they will require water; for if they be stinted, although they will not, as amongst soft-wooded plants, hang their heads and weep, and so the mischief is not perceived, they will nevertheless, when the buds are forming, show the effect by casting them off; and thus when they are brought into a room to bloom they require great care, the dryness of the atmosphere telling upon both the roots and the foliage. I this year found two of mine steadily refusing to open their buds. They formed well, became of good size, but there remained. On examining the pots, I found that this had arisen from the fact of my having said they ought not to be kept dry, and as a consequence they had been saturated with water.

There must, I think, be gross neglect whenever the *Camellia* becomes troubled with scale, which is its worst enemy; and now a good dose of Gishurst, washing it off with clean water, enables an amateur effectually to get rid of it. If they stand, as in small concerns they must do, amongst other plants, they will receive a due share of fumigation, and this will be sufficient to keep down the attacks of either green or black fly. These directions may seem very meagre and commonplace, and so, perhaps, they are; but the articles of Mr. Anderson may be most profitably consulted by those who desire fuller instructions and a more scientific treatment of the whole subject. A different class of readers has been before my mind, and I hope for them they may be sufficient. The varieties of the *Camellia* are numerous, comprising white, pink, crimson, striped, &c.; and I give here the names of a few from which a selection may be profitably made.

Alba plena (the old Double White).
Fimbriata alba, beautiful white; the edges fringed.
Montaroni, white, globular in form. Very good and large.
Ochroleuca, creamy white. Distinct.
Tabricata, satin-like rose. Very fine and good.
Princesse Bacchiachi, crimson. Good.
Master Kosra, veined rose. Very large and good form.
Marchioness of Exeter, cherry rose.
Saccoi Vera, fine rose.
Countess of Derby, striped. New.
Etoile Polaire, striped. A new flower of the present season.

As I perceive Mr. Anderson is going to descend upon scots, and as we shall probably see something of the best next month at Kensington, I hope then to add a few more remarks on this point.—D., Deal.

ICE-PRESERVING.

THERE has been a good deal of pleasant skirmishing already pro and con, on this question, and were it not that I know of a case in point which very much bears out my conclusions, I would scarcely place them in the dignified position of becoming part of horticultural history.

One of the best ice-houses I have ever seen, and one, too, of the most simple pretensions, is a large open shed lying to or against the sunless side of a north wall. Its roof is thatched with straw, after the manner of the old tenements (for there are a few to be seen in one's peregrinations now-a-days), of the poorer class in Scotland, and supported in front with good stout larch pillars some 10 feet or 12 feet apart. Measuring by the eye, I should suppose it was 7 feet high in front, and 13 feet at back. It is of considerable length, holding upwards of four hundred cartloads, and lies at a gradient of 1 in 20 feet. It is hollowed out or concealed at bottom, with a drain running down its centre, so that melted ice can run at the gallop, and the huge iceberg subsides on the spruce branches which intervene between its body and mother earth.

Cartload after cartload is emptied with the least manual labour possible, only the constant hammering with the mallets and throwing-up to get the shed thoroughly well filled. A layer of 2 feet of straw is the only barricading medium in front and both ends; and yet this is a never-failing source of supply, especially during the months of August and September, when, I am told by the best authority, there is a cartload every day

taken from it. This sounds something like efficiency; and is what can you tell me of more economical? But observe, that is not all. There is also a sunk oval brick ice-house in the same establishment, which spends itself annually away, scarcely a vestige to be found there—at a time, too, when most wanted.

Now, I agree with Mr. Beaton that damp is very destructive to ice-preservation, and that if hygrometrical observations were to be taken with a successful and an unsuccessful ice-house, it would abundantly and conclusively test the hypothesis; but I follow with reservation his leading on air-currents in its most literal sense. A current of air, as we read it, has something the same effect on your sense as a breezy day, which I believe also to be fatal to ice-keeping.

On the contrary, if the air is modified on all sides, as in the instance above, or Mr. Beaton's ventilators regulated in such a way as not to admit rushing air, then it will have the opposite tendency of constantly relieving the accumulated moisture without aggravating the liquefaction of the mass.—J. ANDERSON, *Meadow Bank, Uddingstone.*

PEARS IN SCOTLAND.

I WAS very pleased to learn from THE JOURNAL OF HORTICULTURE that my late master, Mr. Anderson, gardener to the Earl of Stair, Oxenford Castle, N.B., had gained the championship for the best collection of Pears at the Royal Horticultural Society's winter show, which collection contained no less than twenty-two distinct dishes, and pronounced by Mr. Beaton to be all correctly named.

When the very unfavourable circumstances are considered under which Mr. Anderson has laboured to bring that choice fruit to the perfection he has—namely, a wet and, comparatively to that of England, a sunless climate it is a proof that Mr. Anderson is possessed of no small amount of practical knowledge of his profession; consequently, on these grounds I will endeavour to give you a brief outline of Mr. Anderson's treatment of wall-fruit trees during the two years I lived there; and, if you think it worthy of a place in your Journal, it is at your disposal.

When Mr. Anderson entered on his duties as superintendent of Oxenford Castle gardens, he found a good many of the wall trees were getting old and worn out; while others were degenerating into a barren unfruitful state, from their roots penetrating into the cold clay subsoil.

To overcome these evils without any addition to his regular staff was necessarily a work of time and perseverance; consequently, the work was performed piece by piece in the following manner:—

Those trees that were next to worn out found their way by degrees to the faggot pile, and those that were degenerating into an unfruitful state had the following treatment:—

A trench was dug along the side of the border farthest from the wall, three and five-pronged forks were then used to loosen the soil away from the roots, and as it tumbled down into the trench it was thrown out with spades or shovels.

During the operation of moving the soil, the surface or most fibrous roots were carefully tied together and moved to one side and the other, out of the way; and what are called carrot roots, or those which had descended into the cold clay subsoil, were cut clean away.

When the soil had been all turned out in the above manner, a few inches of broken stones were put in the bottom of the border, over which was placed about 3 inches of concrete, which was firmly and smoothly beaten with the back of the spade. As soon as the concrete had become sufficiently hardened to allow treading upon it without injury, a few inches of broken stones, or stonemason's rubbish, were spread over it, and then covered with some rough litter, when the soil was again moved back into the border, at the same time well mixing it with a little dung-manure.

When nearly three parts of the soil, which is of a heavy loamy nature, had been got back into the houses, the roots were laid carefully and evenly out; they were then carefully covered with the soil, spreading it the way the roots lay until they were all covered, which prevented them then getting displaced, broken, or otherwise injured, which they would have been very liable to be had the soil been tossed on in a careless manner.

When the trees were thus planted they were merely slung to

the wall for some time, which prevented the wind from blowing them about, and it also enabled them to subside with the soil.

Where it was necessary to plant young trees, the border was prepared in the same manner described for the trees that were retained; but their roots were laid carefully out not more than between 3 inches or 4 inches under the surface. They were then covered as far as the roots extended with rough litter, which prevented them getting injured by frost; and it also assisted the tender rootlets to push away into the fresh soil.

These trees were frequently gone over during the course of the season to rub off all misplaced shoots, and to lay the foundation for healthful and well-formed trees.

The fruit-bearing trees were also occasionally gone over during the summer to remove all useless shoots, and to pinch back others to the third or fourth leaf according to the vigour of the tree, which length prevented the embryo fruit-buds from making wood, instead of maturing themselves for fruit-bearing the following season; and which also enabled both fruit and wood to enjoy the full benefit of the sunlight to bring them to a proper state of maturity; for the value of this every Scotchman knows, as he is very often as much accustomed to Scotch mists as he is to sunlight.

Every good gardener knows that there is no real benefit to be derived from allowing a fruit tree to mature too many fruit in one season, the Pear, of course, included: therefore where they were hanging too many in a cluster—say five or six—Mr. Anderson thinned them out to three or four, and thinned, if possible, so that they would not touch each other when full grown, in order to expose as much of the fruit's surface to the sun as possible, thereby getting large, well-formed, well-floured fruit, qualities which they would not likely attain were they allowed to remain to dig into the ribs of one another.

But there can be no authentic rule laid down for the thinning of fruit. Were all fruit trees in one uniform state of health, and all placed in a like favourable position to bring their fruit to maturity, the thinning of fruit would be a very simple matter; but, as they differ in many instances as widely as east from west, any directions for fruit-thinning may serve as a guide, but not as the rule.

The wall trees at Oxenford had a good watering once or twice during the summer with liquid manure, or soap-suds, an operation which was greatly facilitated by Mr. Anderson having pipes made of strong canvas cloth. These pipes were made by the garden women. When they had two or three coatings of white-lead paint to make them waterproof, and could be joined together to any length by means of brass joints, one end of these pipes was fixed to the pump which was used to force the water out of the pit in which the water was collected, and by it the water was forced through the pipes to any part of the garden—a piece of ingenuity which greatly facilitated the watering of the many fruit trees which Oxenford Castle garden contains, and it abolished any traffic along the walks with water-barels, which cannot be dragged along well-kent walks without giving them an unsightly appearance, at least until they have been again rolled.

Having given you a brief and perhaps rather imperfect outline of Mr. Anderson's management of wall trees, I will, with your permission, also give you a brief outline of his treatment of the Vines; in justification of which, I must say that I have not seen better or more profitable crops of Grapes, not even at Trentham or Keele Hall, all the borders of the latter had been renewed by Mr. Anderson. Two borders remained to be done when I went there, and were done in the following manner before I left; but I will first add that the Vines in these had the appearance of having done well at one time, and they no doubt bore excellent crops of Grapes. But the fruit that were on them then, which ought to have been black or blue, were as brown as foxes,—scarcely one of them had escaped shanking. So to root out the evil, Mr. Anderson commenced at the root.

A trench was dug in front of the border in the same manner as described for the Par-wall. The soil was moved to various parts of the garden, where an additional depth of soil would prove beneficial, or where the old soil would be improved by some fresh being added to it.

The border in question was about 4 feet in depth, and the soil of which it was composed had the appearance of being a good substitute for putty; the roots were few and far between, and those that there were had not a very promising appearance. I believe Mr. Anderson sent a piece of them for the inspection of the Doctor, accompanied by a description of the texture of the

soil, to which the Doctor made not a very complimentary reply; but I must say that the Doctor made a snap on the wrong person that time, for any information which Mr. Anderson gave him with regard to the soil was from his having lived there at one time as under-gardener.

When the soil had been all got out, about 18 inches of stone rubbish was placed in the bottom of the border, the smallest on the top; 3 inches of concrete were then spread over that, and, when dry, straight lines of drain-tiles were laid from the inside-border down to the drain in front of the outside border. These straight lines of drain-tiles were about 10 feet apart. Stones or brick rubbish was then spread over the concrete to the depth of the ribs, thereby securing an impenetrable and perfectly dry bottom for the roots of the Vines.

Whole turves, two deep, were laid along the bottom of the border, then some of the following compost—A rich turfy loam, charred vegetable refuse, lime rubbish, and a little well-decomposed dung; these were well mixed together by frequent turnings previous to their being used. The roots were then laid carefully out, and covered over with the above compost, and the border when completed was a foot above the level of the surrounding surface. I will just add that nothing could give more satisfaction than these Vines did.—G. U. R. J.

GISHURST COMPOUND.

I AM anxious to say a word or two of warning respecting the use of Gishurst Compound. In November last I dressed some Peach trees in the early-house with it, at the rate of 8 ozs. to the gallon, having read in your Journal of some people using it at the rate of 1 lb. to the gallon; but I thought I would be safe by using half that quantity.

I started the house the 1st of December, and by the 1st of January they should have been in bloom; but those trees that were dressed with the Compound lost almost every flower-bud, while it did not hurt the wood-buds. The other part of the house was dressed with a mixture of soft soap, tobacco water, and sulphur. The trees dressed with the latter are beautifully set with fruit and are swelling fast now.

Now, for another instance, I had some Strawberries in ainery with fruit almost ripe, so that I could not smoke them; so I made a mixture of the Compound, at the rate of 2 ozs. to the gallon, and syringed them with it once. I must say, before I go any further, that the Strawberries had thrown up their flower-stems. The next morning the flower-buds were blackened, and all flowers destroyed; that was a week ago. I have only thrown them away to-day (February 26th).—J. E. F.

LORD PALMERSTON'S ESTATE IN SLIGO.

No estate has had a heavier or more successful expenditure bestowed upon it than this. About £25,000 have been laid out in forming a safe harbour for the fishing-boats and other craft, and the seashore village has a good prospect of becoming a frequented watering-place. Our purpose, however, is to point out the planting which has been effected on the sandy sea margin, and for the following notice of it we are indebted to *Saunders' News Letter*:—

"One of the most interesting features of Cliffoney is the Pine plantation, by which the blowing sand-hills have been consolidated, and from being a source of considerable injury to the adjoining land, have been rendered both ornamental and useful. Some fifteen or sixteen years ago, the seashore was bounded by a range of sand-hills which were constantly shifting, and frequently during the prevalence of high winds the sand was scattered far and wide over the fields. Lord Palmerston resolved to try the plan, so successfully adopted in France, of fixing moving sand-hills by the planting of Bent-grass and the *Pinus maritima*—a description of Fir tree which has been found to thrive well even when exposed to the fierce blasts of the Atlantic. The experiment has been attended with complete success. One thousand acres of sand-hills are now covered with a flourishing plantation of Pines, some of which have attained the height of 20 feet. The process of planting is at present going on vigorously, under the superintendence of his lordship's skilful agriculturist and steward, Mr. John Hamon. The course adopted is this—On the blowing sand-hills Bent is first planted, and after a year or two the sand becomes tolerably well fixed. The seed is then

sown, and all that remains to be done is to protect, as far as possible, the young Pines, which will soon make their appearance above the ground. Hares, rabbits, crows, and snails, are great enemies to seedling Pines, but after the first year they are not interfered with. The *Pinus maritima* has been found to thrive well, not only on the sand-hills near the seashore, but on bog or peat lands that have been tolerably well drained, and in various places throughout Lord Palmerston's estate they have been planted extensively. There is a large nursery near Cliffoney well stocked with Larch, Spruce, Scotch Fir, Elm, Holly, Thorn, Quicks, &c."

WORK FOR THE WEEK.

KITCHEN GARDEN.

IF the present fine weather continue, considerable progress may be made in getting in some of the principal crops in light dry soils; but on stiff wet ground it should by no means be attempted. *Artichokes*, if the weather continue mild, give them their spring dressing. *Basil* and *Marjoram*, to be sown in pans or pots, and placed in heat. *Broad Beans*, earth up the early-sown crops; if any were sown in boxes, place them where they can have an abundance of air night and day to harden them off for planting out. *Cabbage*, the autumn plantation should now be filled up, fresh ones may also be made. Sow more seed to produce plants for summer and autumn use; also seed of the red for pickling. *Cauliflower*, if seed was sown early on a hot-bed with Carrots or Radishes, they should now be pricked out on a slight hotbed, or in a cold frame where they can be protected in severe weather. *Lettuce*, fill up any vacancies that may occur in the autumn plantation. Sow some seed of the Cos on a warm border. *Mushrooms*, beds out of doors to be well protected from wet; damp litter to be removed, and its place supplied with dry. *Onions*, autumn-sown ones may be planted out in favourable situations; the general spring sowing may also be made towards the end of the week in light and dry soils. *Peas*, harden off those sown in pots and boxes previous to planting out in the open ground, place them in a cold frame, and let the lights remain off night and day in mild weather. Earth-up the early crops when the soil is somewhat dry. *Radishes*, make another sowing to succeed those sown the beginning of the month. *Rhubarb*, may be forwarded in the open ground by placing a hand-glass, or Sea-kale pot over the roots. *Savoy*, sow seed for the first crop. Re-plant old Box-edgings, and keep them clipped neat and close; repair all other edgings to walks, and take the advantage now the gravel walks are soft to turn and roll them down firmly. Much more can now be done in a day, and in a better manner than when hardened by parching winds and hot sun, and they will be more easily kept in good order afterwards.

FLOWER GARDEN.

When edgings are required to flower-borders, they should be planted as soon as possible. Box, Daisy, Thrift, Camomile, Gentian, *Aubrietia purpurea*, *Campaula punila*, and *Pansies* are all used for that purpose. Plant out Carnations, Picotees, Pinks, with biennials in general, and let all perennials be removed without delay. Look to the sowing of annuals. Finish the laying of turf and all alterations as soon as possible. Finish pruning climbers and deciduous plants. The lawn should now be well rolled, the benefit of so doing will be seen throughout the whole summer.

FRUIT GARDEN.

I shall suppose the pruning, tying, and training of espaliers and all other fruit trees to be done to a conclusion, except, perhaps, in the case of a few *Peaches* and *Nectarines*; the ground to be manured as far as was intended, and forked-up; and the trees that were infested with moss and lichen dressed as before recommended. It will now be a source of great interest to observe the almost daily progress of the buds, which, considering all matters, have rarely been seen in finer condition for the prospect of a fruitful season. Every advantage must be taken of dry windy days to stir and hoc the surface in these departments, and a sharp look-out must be kept to protect the buds of wall trees that are getting in a forward state. Look to the Fig trees, prune and train those that require it, tying or bending the strong shoots down, which will induce them to push out a number of short-jointed bearing shoots. Let all the old leaves be cut clean away from Strawberry-beds, extirpating all the remaining runners.

STOVE.

Any of the *Euphorbias*, *Genesras*, *Eranthemums*, *Geissomerias*, *Justicias*, *Poinsettias*, or other such plants that are going out of bloom to be cut back and removed to a lower temperature for slow breaking, reporting them in a few weeks, and plunging them in bottom heat to produce blooming specimens in November and December. *Begonias* and other free-growing plants to be propagated for autumn blooming.

GREENHOUSE AND CONSERVATORY.

A general dressing of the climbers should take place immediately. When it is desirable that they should bloom late in the autumn it will be advisable to prune late, even after the buds have commenced growing, on the same principle that the Moss and other Roses are successfully retarded by such a course. Pot *Pelargoniums*, *Cinerarias*, *Calceolarias*, &c., and keep them close for a few days after the operation. Green fly to be kept down by fumigation. Pot *Verbenas* to supply cuttings. *Heliotropes* may also be placed in heat for the same purpose. *Fuchsias* for general decoration, or as single specimens on grass, to be brought from their winter quarters without further delay, and introduced to a warm end of the greenhouse; but where there is bottom heat to spare, select some of the best plants, disroot and re-plant, and plunge them in a bottom heat of 75°.

FORCING-PIT.

Continue to introduce plants of *Hydrangea hortensis*, *Roses* in varieties, *Pinks*, *Carnations*, *Rhododendrons*, *Kalmias*, *Ledums*, *Pelargoniums*, *Heliotropes*, *Azaleas* in variety. Sow *Balsams*, *Cockscombs*, *Globe Amaranths*, &c.

PITS AND FRAMES.

Plants which are growing in these structures will require to be carefully watched, as the warmth occasioned by the increased power of the sun in the daytime will induce a too-rapid progress at the expense of constitutional strength and vigour; it is, therefore, desirable to keep them as cool as may be found to be practicable, by allowing the free ingress of the external air. Anything like close confinement when the sun is shining on the frames will certainly be injurious; at the same time, if the air is very keen and cutting, the lights must be opened on the side least exposed, and in such a manner as to prevent the cold draught from acting injuriously on the plants. *Articulas* should have the decayed and decaying leaves removed, and, if not already done, a top-dressing of fresh compost. A gradual increase may take place in the supply of water. *Carnations* and *Picotees* in pots require to be kept clean and comparatively dry, and they should have the surface soil about them frequently stirred and lightened-up. The compost for potting them in due time may be got ready; it may consist of one-half turfy loam, one-fourth of manure reduced to the state of fine mould, cow-dung is preferable where it can be procured in a decomposed state, and one-fourth of coarse gritty sand, which may be read or river sand.

W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

Doing Things Seasonably.—The continual drizzle that has followed the frost has considerably delayed a number of outdoor operations. It is always true economy to avoid going to a job that would necessitate the making of a second. For instance, we have known work done on a lawn because the manager was such a disciple of order, and would finish one thing before he commenced another, that the making all right afterwards took up more time than the job itself would have occupied under suitable circumstances, so that on the question of economy alone, the men might just as well have been sitting in a comfortable place as at work in unsuitable weather. I know of no gardener, however large or small, where there would be any necessity for men being idle in the worst weather if the work is done with judgment. Some years ago I had occasion to go to a place twice in February; at one time the men were wheeling gravel, with the wheels of the barrows half buried in mud, and the men looking as woe-begone as half-drowned rats. At the other visit there had been a crisp frost, and the day was bright and clear, and the men were mostly in a vinery, cleaning and washing Vines, and obliged to give plenty of air to prevent the sun scorching their heads. The Vines would just have been the work for the wet day, or even for part of a day that was wet, method or no method notwithstanding.

Cauliflower has stood the winter well as yet in frames, hand-lights, and out of doors; but where this is not the case, a few should be sown on a slight hotbed, along with Lettuces, Cabbages, &c. I often find that Lettuces so sown, pricked out, and gradually hardened off, come in pretty well as soon as those that stand the winter. The Hammersmith Cabbage Lettuce is about the first to come in out of doors, after standing the winter. Lettuce generally stand it best at the foot of a wall—the ground, if not hard before, having been trodden to make it so, and then just scratched enough with a rake to bed the seeds, or the least covering of fine stuff should be thrown over them. If this is done from the middle to the end of September, the plants, from the hardness of the ground, generally grow short and stubby, and the frost and continued rains have less effect on them. Where these vegetables are in plenty from the autumn sowing, it will be time enough to sow Lettuces out of doors in the middle of March; but Cauliflowers should be sown about the same time in a little heat. Though slight hotbeds are spoken of for this purpose, yet a flower-pot will often be large enough to sow in for small gardens. For instance, Cauliflower seed sown in a pot at that time might be placed near the fireplace; and when the seedlings appeared the pot could be transferred to the greenhouse or window, and the plants individually pricked out when they are from $\frac{1}{2}$ inch to 2 inches in height.

Planted more Potatoes in beds, the soil being rather wet for out-of-door work; thinned young Carrot-bed; sowed a few more Radishes; transplanted Dwarf Kidney Beans out of seed-box into 8-inch pots, and sowed more, which most likely will be transplanted into beds—the transplanting until April enabling us, we think, to get more pots from the same amount of rows. Earthed-up Potatoes in pots, and transferred Peas from small pots to larger ones, to produce their pods in. Found we had no proper place for sowing Peas in turf, to be transplanted next month, and therefore sowed some in good-sized pots; also sowed Beans. In general, we would prefer shallow boxes to either pots or turves; the only fault we have with the latter, being that if the turves are at all close and rather sour in quality they seem to prevent the neck of the plants expanding healthily and freely after being turned out. When turves are used we prefer them to be at least 2 inches thick, 4 inches wide, and 12 inches long. These are laid on a suitable place, such as the floor of a Peach-house or vinery at work, grass-side downwards. A hole is then made in the centre of each, 1 inch wide and nearly 1 inch deep. The seeds are sown along, watered, and then covered with fine sifted soil or leaf mould. When the Peas are 4 inches high they should be moved out and hardened off by protection in a cooler place before finally transplanting. This moving can be done much better in boxes—say 9 inches wide, 6 inches deep, and 3 feet to 4 feet in length; and then in planting in patches from the boxes, it strikes us there is more of a check given at first, which hastens fruiting or podding, whilst the plants grow away freely afterwards.

FRUIT GARDEN.

Pruned Plums, Apricots, and a few Peaches, in five hours as we could get at them. Got a flat board and waved it briskly with the hand a few inches from the bloom in the Peach-house, to scatter the pollen, especially when there was a little sun, as on the afternoon of the 15th. Dusted with a feather Strawberries in bloom, and commenced in favourable times to paint the Peach trees, so as to smother up all insects and their eggs, having more faith in this daubing than in the mere materials of which it is composed. A little tobacco water, soft soap, sulphur, and clay, are a good mixture for such a purpose. I notice a correspondent recommends painting a wall all over with Gishurst Compound, to fill the holes and prevent the woodlice getting into them or trying to open them, telling us that they will not touch it. On the score of trouble, however, I still think that the double lime-wash would be the best, and I am doubtful if the Gishurst would prevent at these gentry making holes for themselves as soon as it was dry. At any rate, I have seen them lying in boxes of the Compound, and I also recollect, when I washed the outsides of some pots with soft soap and sulphur, and a little oil in the mixture besides, to prevent them getting at some choice delicate seedlings, they not only managed to waddle through the rather liquid stuff, but seemed to live on it too. The only two common things which I found they would not pass were tar, so long as it was liquid, and water. A canal of the latter 1 inch deep, and 1 inch wide, seems to baffle them, as they are poor swimmers,

even when they try. The modes of trapping have been often referred to.

PLANTS AND PLEASURE GROUND.

Proceeded with potting and cuttings much the same as last week. Potting a few variegated Geraniums from boxes where they stand thick, placing them singly in small pots, and giving them a little heat, and whenever the roots begin to bill will turn them out into an intermediate-bed to save watering and get the pots.

WALKS.

On this subject we have had several inquiries. First, as to the position of drainage; second, as to the depth of walks; and thirdly, as to the best material—gravel, pebbles, flags, or home-made asphalt. We shall now only say, that for six feet walks we prefer a single drain in the middle with gratings at the sides. For a twelve and on to a twenty-foot walk we would prefer a drain at each side. For walks on steep inclines it would be advisable to pitch the sides with pebbles, and have a cross open drain, such as four-inch iron pipes with an opening of an inch, placed across the walk, which would prevent the running of the walks in heavy rains, though this can be greatly avoided by using open bottoms for walks, however smooth and fine the surface. Where pebbles of somewhat equal size can be got, walks will be not only more lasting but much cheaper than gravel, and flag-stones, though dearer at first, will ultimately be far cheaper than gravel. The two most expensive things in the long run in a garden, are a well-kept lawn and a good gravel-walk. Just think of the first making of the latter, the constant repairs it needs, the ever-anti-anon turnings, brushings, sweepings, and rollings, and then think of the switch now and then over a stone pavement, and the little trouble it gives, if allowed to get a little mossy. But, after all, nothing is so agreeable to the feet as a nice gravel walk, even asphalted ones will not compare in this respect with it. The other matters at a future time.—R. F.

TRADE LISTS RECEIVED.

Descriptive Catalogue of Florist's Flowers, &c., cultivated and sold by Downie, Laird, and Laing, Stanstead Park, Forest Hill, and at Edinburgh. This is one of the best catalogues of florists' flowers we know; so full, and so useful is it.

A Catalogue of Select Vegetable, Flower, and Farm Seeds, by William Cutbush & Son, Highgate, N., contains good selections of seeds, with descriptive remarks.

A Catalogue of Pelargoniums, Fuchsias, Verbenas, Petunias, Dahlias, &c., by George Smith, Tollington Nursery, Hornsey Road, London, N., is another of those first-class Florists' Flower Lists; these being a speciality for which Mr. Smith has long been celebrated.

A Select Catalogue of Flower, Vegetable, and Agricultural Seeds, by B. S. Williams, Holloway, N. A nice pamphlet, of 56 pages, containing well-selected lists, and good descriptive notes.

Choice Vegetable and Flower Seeds, by James Dickson & Sons, 102, Eastgate Street, Chester. This is a very neat and well-kept-up catalogue, and has the evidence of care having been bestowed on the preparation of it.

A Catalogue of Vegetable, Flower, and Agricultural Seeds, &c., by Robert Parker, Tooting, S., is also a well-selected catalogue, and contains numerous useful notes on the articles offered for sale.

Descriptive Catalogue of Flower Seeds, Vegetable Seeds, &c., by R. J. Edwards, 222, Strand, London, is a good list of flower seeds arranged in the tabular form.

Catalogue of Vegetable and Flower Seeds, &c., by Dickson and Brown, Corporation Street, Manchester, is a quarto pamphlet, abounding in descriptive notes and cultural information.

Catalogue of Nursery Stock, sold by W. H. Rogers, Red Lodge Nursery, Southampton, contains a list of the usual stock of a well-appointed nursery, and especially of the Rhododendrons and Roses.

Catalogue of Culinary, Agricultural, and Flower Seeds, by E. P. Dixon & Sons, Hull. This is the old double-sheet form of catalogue, very unusual now-a-days. It is evidently prepared to facilitate the giving of orders and save purchasers the trouble of writing out the list of articles they require.—Blank columns being furnished in which to insert the quantities required opposite each article.

SPRING PRUNING (*A Regular Subscriber*).—No *Spiræa* or *Weigela* must ever be pruned in the spring, except to thin out dead shoots or very old shoots. The time to prune them is once in ten or twelve years, and they get too big for a place. There is a most mistaken predilection abroad about pruning all sorts of plants whether they need it or not. Your *Spiræa*, whatever the kind is, and your *Weigela* trees will not require more of them by pruning for the next seven years certain; so say no more about pruning them just yet.

POTTING BEDDING GERANIUMS (*Idem*).—It would be a very good plan to pot old Scarlet Geraniums now, which have been at rest during the winter in boxes and all manner of ways. All their very small roots are now dead as those of our own stock, and we have to cut them all back to the quick, or live joints; but we have no notion where to put them now, so they must chance it as they are for six more weeks at the least. They must not be cut back, however, at the time of spring potting, as so many kinds of them are apt to perish or damp back in the shoots just at that period if pruned; but as soon after potting as they are full of leaves they may be reduced for spring cuttings.

GLADIOLI FOR BEEDS AND POTS (*Idem*).—The best Gladioli for pots are those of *Andalensis* as they call them, and of the cheap sorts of them *Breachyensis* is the best. *Bowen's* is also an excellent bedder of itself as those of our own stock, and both are of the cheapest. Then *Lighter*, or *Aristo* and *Arclin* (old), *Berenice* is also fine and very cheap, and *Countess* (old) is the cheapest of all, and is as good as many are at *7s. 6d.* a-piece. *Hélène* is a fine light kind, cheap as *Impératrice*, which is also of a whitish cast, and cheap. *Madame Herin* is a thin light one, not at all inferior to the more showy and dearer varieties.

ROYAL HORTICULTURAL SOCIETY (*Quarter*).—If you write to Mr. Murray, the Under-Secretary's office, Kensington Gore, he will have you proposed as a Fellow. The entrance-fee is two guineas, and the annual payment the same. We know of no mode of obtaining a situation such as you name except by advertising. The office of book-keeper to the Society was vacant recently, and there were three or three hundred applicants.

CITRUS MELON (*As Liguiree*).—The cultivation it requires is the same as that required by any other Melon.

FERN ALTERED IN FORM (*Sabina*).—Your Fern (*Iris ariztica*) is not eaten that we can discover, but has sported so far as to produce some of its parts in an abnormal and deperivated state. It may have been inherent in the plant from the spore—a true sport, in which case the plant will go on growing in this way, or it may be purely accidental, as one would say, and then the plant will grow out of it.

LILIUM GIGANTEUM CULTURE (*A Young Gardener*).—Grow it in a 14-inch pot, using *bruy* loam and a little peat for soil. Keep it rather dry until it begins to grow, and then give it plenty of weak manure waterings, taking care that the whole ball is moistened. Keep it well supplied with moisture. When the leaves begin to decay, gradually allow the soil to become dryish. When fresh potting is required, do it whilst the leaves are yet green after flowering is over. This Journal is bound in half-yearly volumes, commencing alternately in April and October. We do not know when another edition of the *Cottage Gardener's Dictionary* will be published.

EMANCIPATING FERNS (*A Subscriber*).—There is no better mode of eradicating the common Brake Fern (*Urtica aquatica*) than by keeping the ground constantly cut down as they appear, and sowing soil thickly over the place.

NAMES OF PLANTS (*G. H. J. W.*)—*Gratia simplex*. The leaf is apparently that of some species of *Hakea*. Both are greenhouse shrubs; the first preferring a sandy and peaty soil, the second preferring a little more loam. (*Amorpha*).—1, *Lilium album*; 2, *Rosa glauca*. We believe the *Tangutina* cultivator, introduced in Brazil to be a distinct species, and so are the other two which you mention. The *Orchetea Orange*, very so all, is the *Citrus japonica*; and the *Mandarin Orange*, very large, is *Citrus nobilis*. *Quercus*.—1, *Q. coccinea*; 2, *Turkey acuticarpa*; 3, *Pinus pinaster*; 4, *Abies canadensis*.

put in a spoon over the fire with a little milk until warm, and with a quill put a little in its mouth, and the remainder in the cage in a small pan, to be repeated for two or three days. Give it boiled egg, maw and hemp seed, with the food it has been accustomed to. The bird should be kept warm.]

THE CANARY AND THE BRITISH FINCHES.

(Continued from page 426.)

MULE BREEDING.

The crossing of different species of birds, or Mule-breeding, is an interesting amusement much in vogue among bird-fanciers, and it may be divided into two branches; the first or general plan being that of breeding from a hen Canary and some other male bird—the Canary being a domesticated bird and breeding readily in a cage, it is by far the easier method, and consequently more practised.

The second, where the hen or both parents are of a wild or undomesticated kind is much more difficult, and the Mules thus produced are much less common, and consequently more valuable; for it must at once be admitted, that where the hen is of a wild race and does not readily incubate in confinement, the greater trouble entailed in the rearing of such Mules must necessarily influence their production, and the greater trouble in procuring them will enhance their value. Again: the more nearly allied the species, and the greater the resemblance in the natural habits, the easier will union be brought about. From this cause Linnet and Goldfinch Mules are by far the commonest, while those birds that are less similar in those particulars are the more difficult to bring together to a successful union; as for instance, the Chaffinch, Bullfinch, or Yellow Hammer, of which sorts Mules with the Canary are very rare.

Having paid some attention to the raising of Mules, I will, in this chapter, offer a few remarks as a guide to the intending amateur. In the first case it is usual to select young and healthy hen Canaries, and mate them with cock birds of a different species. Of all birds that I am acquainted with that inhabit this country, I consider the Grey or Brown Linnet the nearest allied to the Canary, and it therefore follows that it is the easiest to couple with the Canary, and the most certain to produce Mules; even a fresh-caught cock Linnet, if taken in spring will often readily pair with a hen Canary; and she, being a tame and already-domesticated bird, readily builds her nest, lays, incubates, and rears her young in confinement. If, however, the cock Linnet is rendered tame and partially domesticated by being taken from the nest, brought up by hand, and used to the society of Canaries, they will breed so readily with them that there is scarcely any more trouble in breeding Linnet Mules than in rearing Canaries. These Mules are generally of a greyish colour, intermediate in shade between a Grey Canary and a Linnet. Occasionally Pied Linnet Mules are bred, and these are considered more valuable as being rarer. The Linnet Mule is, however, mostly prized for its song, in which it is thought, if properly trained, to excel all others of the Finch tribe. Next in order stands the Goldfinch for tractability, and the ease with which it mates with the Canary; and as its colours are more beautiful, perhaps there are more Goldfinch Mules bred than any other kind. There are, however, several varieties of, perhaps more properly speaking, sub-varieties of Goldfinch, and they vary much in disposition. I have never found any difficulty in breeding from any of them, but it is as well to have them somewhat tamed—either raised from the nest, or kept in a cage over one year. The Goldfinch is, however, a restless and rather mischievous bird, and sometimes takes an ecological turn that is very provoking. In such cases he must be watched and shut off from the hen when about to lay. The egg having been laid and removed, he may be let into the hen again each time until the hen sits, when he should be removed or put to another hen. From my own experience, I should say that the dark Goldfinch with greenish wing, shoulders, and dark legs is the most given to these mischievous propensities; while the dark light-coloured, or as it is sometimes called the Pear-tree Goldfinch, is the most tractable and produces the handsomest Mules; the raising of these and all other Mules is performed similarly to the breeding of Canaries as previously described.

Goldfinch Mules are also prized for their singing when they

JAVA SPARROW AFFECTED WITH COLD.

Etta has two Java Sparrows, one of which has attacks of asthma, lasting sometimes two or three hours. The bird looks ill and is thin, and does not eat much. She would be glad to know if anything would cure it, and what treatment it should have. It will only eat Canary-seed and a little rice. She has tried hard-boiled egg, biscuit, and bread and milk, but the bird will not touch either. A drop or two of sherry given on a camel's-hair brush during the attack sometimes seems to do good. Should the birds be kept warm? The attack begins with violent coughing, which subsides into a sort of croaking, the bird opening and shutting its beak incessantly; it eats nothing during the attack, but at intervals is pretty well though rather puffy.

[The bird has a cold; give it a little sweet oil in the mouth with a quill—say two drops, and a little moist sugar and bread

are taught some particular strain or fancy song, and according to their performance are they valued.

The generality of these Mules are of a dull colour, intermediate between a Goldfinch and a Grey Canary, being much less handsome than the Goldfinch, and no more value than a Canary, unless, as before mentioned, of a good song. But the great desideratum of Goldfinch Mule-breeders is to produce them beautifully and accurately Pied; when this is obtained, and feather combined with song, they become very valuable. These may be either mealy or jouque Pies, and the more regular the marking the better. In the mealy the ground colour of the plumage is white, while in the jouque it is yellow; the nearer it approaches to jouque or orange the more it is valued. The marking that is most aimed at is to obtain a clear body with the wing-shoulders as nearly like the Goldfinch's as possible. There is mostly a mark across the eyes, and some of the tail-feathers are dark; in this case they should be equal on either side; but it is better that the tail be all of one colour. The pinion or flight-feathers are usually white, with the yellow mark of the Goldfinch on them. Sometimes the Goldfinch Mule is quite clear and free from all marks; but such are rare, and I once saw a cinnamon Pied.

Many curious notions are advanced by fanciers who have been unsuccessful in breeding Pied Mules; but the plan which I believe is most successful is to use hen Canaries that are bred expressly for the purpose. These are selected of the requisite Pied-marking birds that have been bred from Pies for several generations. The more accurate the division of colour the better. These are bred in-and-in for a generation or two, as, for instance, father and daughter, and then brother and sister, or "bred down soft in colour" so as to produce a tendency to throw light or albino young. Of course this incestuous breeding induces degeneracy, still the cross with the Goldfinch gives more vigour, but generally retains the light colour. This I am informed is the whole secret of successful Pied Mule breeding. After the Goldfinch come the Siskin or Aberdevine, the Twite, and the Redpole, all of which will breed with the Canary without any very great trouble.

Then the Greenfinch, Mules from which are somewhat rare, on account of the pugnacity and rough gallantry of this strong bird frigitating the more timid hen Canary; yet if the Greenfinch is brought up from the nest, kept tame till he is two years old, and then put to a large robust hen Canary, they will often breed well. Some of mine would feed their hybrid offspring as well as a cock Canary; but they are not always to be trusted—many being very vicious. The Chaffinch, Sparrow, Bullfinch, and Yellow Hammer, have also been known to breed with the Canary, for which purpose they should be brought up tame from the nest, and accustomed to the society of Canaries; still better if they were raised from the egg by Canaries; but even then there is so much dissimilarity between the nature of the birds, their habits, food, sexual signs, and language, that it is very rarely they will couple successfully.

The second method of breeding Mules from the hens of wild birds is attended with more trouble than when hen Canaries are used—not that a cock Canary will refuse to mate with other birds, but because the hens, even though reared from the nest and kept tame, will rarely build and incubate in cages. Thus they should be bred in a room or aviary; or if in a cage, then it is generally necessary to keep Canaries to hatch and rear the eggs that may be dropped by these birds. It is said, as the Mules take more after the father than the mother, that Mules bred from a cock Canary are handsomer than those bred from a hen Canary; how this may be I cannot say from my own experience.

When both parents are of wild undomesticated species, the trouble and uncertainty must be proportionately greater; consequently the Mules are on that account more highly prized. Both birds should be reared from the nest, rendered as tame and domestic as possible, and they should be accustomed to each other in early life. If separated just before the breeding time, and brought together again at the right season, they will sometimes couple; if eggs are the consequence they should be reared under Canaries.

Hybrids were exhibited between the Goldfinch and Bullfinch, Goldfinch and Greenfinch, Goldfinch and Grey Linnet, and also between Greenfinch and Grey Linnet, at the Crystal Palace Bird Show, January, 1862.—B. P. BRENT.

BEEES NATIVES OF ENGLAND.

BEEES are mentioned in some of our earliest national records, and the mention of them is such as demonstrates how highly they were valued. Nor is this a cause for surprise, inasmuch as that mead or methglin was the choicest drink of the Britons' feasts; and although the household of the Prince of Wales, one thousand years ago, comprised but twenty-four officers, the eleventh of them was the mead-maker, and he ranked next before the royal physician.

So highly was superior mead prized in those days, that one of the royal privileges was to have the first offer of every cask that was intended to be sold.

We are accustomed to consider our forefathers of those days as rude and barbarous, and they were so if measured by our present standards of habits and education; but compared with contemporary nations they appear to advantage, for their laws and customs were fully equal in good sense to those of their neighbours on the Continent. As an illustration, we will quote from the laws relative to bees enfold by Howell Dda, who was chief ruler of Wales about A.D. 910.

"OF THE PRICE OF BEEES.

"An old hive is valued at 24 pence.

"A spring swarm at 16 pence.

"A second swarm at 12 pence.

"A swarm from a first swarm at 12 pence.

"A swarm from a second swarm at 8 pence.

"A swarm after the Calends of August at 4 pence, and that shall be the price until the Calends of November.

"After the Calends of November an old hive is valued at 24 pence; and the swarm which came off after the Calends of August shall not be considered as an old swarm before the Calends of May, and then it shall be valued at 24 pence.

"Three huntings are free (that is, you may follow them upon another man's ground), of a swarm of bees settled upon a branch, and of a Fox, and of an Otter, because they have no certain abode.

"Bees were first born in Paradise, and were driven thence on account of man's sin, but God blessed them; therefore mass ought not to be sung without their wax being present.

"He who finds a swarm resting on a branch in another man's land shall receive 4 pence from the possessor of the land, if the latter wishes to retain the swarm.

"No swarm shall be valued at more than 4 pence until it has remained quietly for three days and three nights in the same place, and that in fine weather. Of those days the first is required to ascertain whether it will settle; another in examining whether it will cluster; and the third whether it will continue here.—(Wotton's *Leges Walliæ*, page 251.)

BEEES AS CHEMISTS.

If the opinion of one of our most experienced chemists will serve to throw any light upon the question, now under discussion in your pages, as to the origin of honey, it is at our service.

A few days since, in conversation, his remarks were to this effect—"I cannot imagine any chemical agency in the stomach or honey-bag of the bee. The artificial syrup of sugar given as food is itself a very near approach to that derived from flowers naturally, and it remains but a few seconds or minutes in the bag it passes through. The slight warmth could have but little effect fill the syrup was emptied into the cells of the combs. Here it might acquire a little of the aroma of the hive, and of the wax in which it had been deposited. The absorption of a portion of oxygen from the atmosphere would tend to give it more consistence possibly, and you may call the result honey if you please."—H. TAYLOR.

THE SUPER-POSING DIFFICULTY.

STREELY your excellent correspondent, "B. & W.," jests when at page 368 he says, "The tone of the 'BENFLESHSHIRE BEE-KEEPER'S' remarks, who seemed to deny the possession of eyes and practical knowledge to our respected apiarian friend in Devonshire," as I cannot suppose my remarks would bear any such construction. On the contrary, I can assure "B. & W.," that I entertain a most favourable opinion of his own practical knowledge, as displayed in his useful and interesting work "The English Bee-keeper," the perusal of which afforded me not a

little pleasure, and I hope some profit; and that his ideas in the main coincide with my own on the "A. W." case.

"A DEVONSHIRE BEE-KEEPER'S" masterly contributions are too highly appreciated by the apianian readers of THE JOURNAL OF HORTICULTURE to require any commendation from my pen, and that an apianian so thoroughly practical should differ with me, that bees winter in the upper portion of their hives, the sum and substance of this weary controversy, seemed to me quite inexplicable, unless it were that his salubrious climate caused a variation from their usual practice in our northern regions; as in Scotland any bee-keeper not already aware of the fact can satisfy himself by simply inverting his hives at that season, and he will find his bees packed up between the combs proportionately to the severity of the weather, and into so little space as to cause him to entertain some misgivings as to their after-prosperity. In keeping with the returning warmth will they expand themselves downwards into a bulk surprising, and with a determination as the spring advances, so well illustrated in Mr. S. B. Fox's "pretty little case of super-posing" described at page 347.

The rule with one hive holds equally good with two united, always providing there be a free and uninterrupted communication between the combs; it must be owing to the want of this and a more general acquaintance with the movements of bees to and from supers in the south, as noticed in my last paper, that so wide a diversity of opinion on this subject is to be accounted for.

I cannot close this controversy on my part without expressing regret that the erroneous construction "A DEVONSHIRE BEE-KEEPER" put upon my meaning by the absurdity "that bees are disposed to adopt the upper compartment of their hives as their breeding place, &c.," looked so like a wilful mis-representation as to provoke the hasty rejoinder that I would not discuss apianian matters with him for the future, but upon dispassionate reconsideration I am disposed to entertain the idea that this was not his intention, and I would be glad to learn from himself that such was the case.—A RENFREWSHIRE BEE-KEEPER.

[I have much pleasure in assuring "A RENFREWSHIRE BEE-KEEPER" that the "erroneous construction" which I put upon his meaning was anything but "wilful." When I penned the offending passage in page 180, I really believed that his opinion was that bees were "disposed to adopt the upper compartment of storified hives as their breeding place," at any rate during winter. As I now learn from him that I altogether misapprehended his meaning, I have no hesitation in apologising for and regretting the mistake—a regret which would have found expression on the instant if I could have believed that it would have been accepted—and once more beg to shake hands over our little difference. My own opinions on "super-posing," as modified by the light thrown upon it during this discussion, are identical with those stated in reply to "A. W." in page 429. Whilst deeply sensible that I have yet much to learn in apianian science, I will not deny that I feel gratified by the compliment paid me by "A RENFREWSHIRE BEE-KEEPER," whose able contributions on the subject entitle his opinions to that respect which they have always been held by.—A DEVONSHIRE BEE-KEEPER.]

UNITING BEES.

I WOULD crave a portion of your valuable space to fulfil a promise recently made of sending you some remarks on "uniting," premising at the outset that I know of no infallible mode of accomplishing this desirable object; regretting at the same time the admission may disappoint the expectations of your correspondent Mr. Hood. The following observations are merely a few hints from my own experience, guided by which I have hitherto been happily exempt from many of those fearful onslaughts described by some of your correspondents.

I have found it a pretty safe rule in uniting as well as in all manipulations with bees; and I may say the same holds good with regard to animals generally—approaching them with a steady cautious firmness, so as not to startle or alarm them, and, if possible, accomplish the desired object without their knowledge, or at least before they have had time to comprehend the result aimed at. All half measures are decidedly bad. Should they once get fairly aroused, there is no alternative but to adopt the opposite course, and by a thorough overturn, and bringing a power so great to bear upon them as will fairly confound,

and leave them in bewildering terror at the mercy of the operator.

Acting on this rule, I take care to place my swarms or beat-out bees in nives of the same dimensions with those to which they are to be introduced; and, as they are all (saving dome-shaped ones) furnished with bars and slides, they afford considerable facility for this operation, besides admitting of being employed either then or at any future period, singly or as portions of storifiers. Emigrants are all the more welcome arriving with well-filled purses, and bees make no exception to the rule. On swarming they take care so to provide themselves. On driving, a like opportunity is afforded by allowing a minute or two's grace before forcing the ascent. I believe, too, that the success of the operation in a great measure depends on the upper hive being, if not filled, at least nearly so, with combs; as where a vacancy exists between the two bodies of bees, fighting is much more likely to ensue. The empty space may be lessened by the removal of an eke, could such be spared; if not, and the hive be but partially filled, the mode pursued with dome-shaped hives had better be followed. Knowing the predilection bees have to ascend, notwithstanding what some of our southern friends may say to the contrary, I invariably place the stock-hive uppermost, slipping on the other below as cautiously and quickly as possible; its slides being gently withdrawn, a good puffing of tobacco smoke to both from the pipe of the assistant, the entrance of the upper closed, is simply the whole operation; the morning light usually revealing a dead queen, the only occupant of the lower hive.

Should the weather be warm the proceeding is attended with little risk; if cold, with the wind from north or east, more hazardous, and, in such circumstances, better postponed. If fighting at any time unfortunately ensues, the combatants seize each other with the ferocity of bull dogs, and only like them can be separated by a tight compression of the throat of each; this can be effected by running in the sliding door (described in No. 9). The results may be watched and tempered by looking through the back window; or, the fumes of the weed answer a like purpose.

All junctions should be effected dry. The plan of sprinkling with honey or sugar and water, as recommended in some bee-books, is decidedly objectionable. Dampening the combs of a weak colony at the end of the season from insufficiency of internal heat, has generally the effect of inducing unwholesome mouldiness.

Should the stock-hive to which the bees are to be added be dome-shaped, the junction of course is as easily effected, provided the lower hive be flat-topped and fitted with bars and slides as already described; but if the bees to be added are in a dome-shaped hive, then the other alternative hinted at above must be resorted to. About the same time in the evening I set a little low table beside the stock, and boldly invert it on the table if flat-topped; if round, I set it in a straw hive from which the flat top had been removed. This being tapered, the one end suits a small, the other a large-sized hive. A small cask or any cylindrical vessel answers the purpose, the assistant holding the hive with the bees to be added about an inch or so above the other; but failing such being at hand, it is easily accomplished by the operator himself encircling it with his left arm, and bringing the open palm of his right hand down on its top, with two or three smart blows the bees are at once precipitated *en masse* into the other; a board ready at hand is placed in a twinkling on its mouth, and the entrance stopped. The hive is then reinverted and placed in its position. This may seem to the beginner a rather daring operation, but it only requires a little practice or nerve, which every bee-keeper must in some measure possess. The hive being disturbed at such an hour, the inmates, weary with their day's work, only raise at first a sleepy buzz, and before they can collect their wits both parties are thrown together, each emitting strongly at such a moment their own peculiar odour, commingling all the faster from the closed doors; so that before all have gathered up into the combs the alien is undistinguishable from the native. Should they receive a little smoke, the door may be opened all the sooner; if not, it had better be kept closed till they have fairly settled. Were it left open, in their bewildered consternation the probability is they would pour forth in a stream over the landing-board never to return—darkness, and possibly, a wet night setting in.

By keeping in view the principles noted above, I have united the last season ten colonies into five stocks with completed suc-

cess, as mentioned at page 78, and have generally escaped most of those distressing combats so painful to the apiarian to witness; indeed, at the present moment, I only recollect of two such, both of which might have been averted. The one, a friend sent me a quantity of bees removed by fumigating his hives, of which I was ignorant at the time; and, although gorged with food, was much chagrined the following morning to find, not the customary dead queen, but nearly all the new comers on the floor-board dead: had I only known they had been fumigated, a puff or two from my fumigator to the stock previously would have kept all right. The other case occurred some years ago, that of a large late prime swarm, which, after being newly hived, missed their queen, and began to go back. On the spur of the moment I hastily resolved to unite them at once to a stock formed of two prime swarms of the same season, with the view of expediting the completion of a beautiful super, saving in addition further watching, and a second exodus, and, therefore, placed them below the stock and drew the slides; but found the lower portion of my united states as averse to union as southern planters at the present moment. They, true to their old allegiance, would be off, hurried doubtless by a vigorous attack in their rear from the in-door occupants of the stock; the rapidly increasing band of returning foragers in front would likely be suspicious the departing strangers' well-distended honey bags were laden from their own store, and gallantly charged them in front to the cry doubtless of "stop thief!" Between two such fires the poor colonists soon displayed an amount of killed and wounded I never wish to see again. Any stragglers escaping returned at once to their old hive, which did not swarm again; the juncture, as such a rash proceeding justly merited, proving a total failure.

Removing bees from frame-hives is easily effected by carrying the hive to a little distance from its stand, raising the frames one by one, and with a few feathers sweeping the bees from off the comb on to a table, where an empty hive is placed slightly raised on one side, into which they take refuge, the frames as cleared being set into another covered empty hive hard by.

Should the hive not possess this facility, bees, in my opinion, are best removed by driving. Like your contributor Mr. Hood, I too have tried fungus (Neighbour's) at all seasons, and never witnessed the bad effects therefrom complained of by some correspondents, possibly from using it more sparingly, the mortality rarely exceeding the few bees over-dosed about the mouth of the fumigator; still I much prefer the simple, more economical, and decidedly preferable plan of driving, by which I can at all times much more satisfactorily empty the hive. Fungus causing many bees to take refuge in vacant cells from its fumes, for the last two or three years I have almost entirely discontinued its use. I cannot account for so experienced a bee-keeper as your last-named correspondent meeting with a want of success in so simple an operation; possibly it may be ascribable to a too-continuous driving, coupled with the hives fitting too closely—in other words, to a want of fresh air. I would recommend him giving it yet another trial the coming season, and perhaps he may then kindly report progress. The way I go to work is this: Selecting the middle of a fine day when the bees are very busily at work, I invert the stock, setting the empty hive upon it, both entrances being closed; and after placing an empty hive on the stand to attract the foragers, carry the hive to a table previously placed beneath the shade of a tree at a little distance, a few warning taps all round to begin with, then a pause of a minute or two to allow the bees to fill themselves, and then with the open hands beat sharp and quick; another pause, and if the ascending hum is heard, the hive may be safely raised slightly on the opposite side from where the main body of the bees is ascending. This admits the fresh air, stimulating the movement; and should a veil or bee-dress be worn at all at this point, it can then be thrown aside, as bees never sting after the ascent has begun. The hive may be kept in that position and the beating renewed at short intervals, till after a few minutes the bees will be found to have vacated the lower hive; they are then set down on their old stand and joined by the perplexed foragers. Any stray bees lurking in the emptied stock can be swept out with a feather. By driving my hives chiefly at the end of the season, when there is little, and at twenty-four days after swarming, when there is no brood, my experience is more limited of the difficulty Col. Newman speaks of; still I have resorted to this mode at all seasons, and was never yet beat off in driving a hive. No doubt the Colonel is right so far, that when there is a large quantity of brood maturing, it is not so rapid or thorough from the tenacity with

which the nurses cling to their charge. At such a time, however, unless forced by some strong compulsion, I prefer leaving my hives undisturbed.—A RENFREWISH BEE-KEEPER.

WHAT THE BEE SAID.

A SWARTY time we had last season—
 St. Swethin rain'd his out on all reason;
 And, though we toil'd from morn to night,
 You found our stock of honey light.
 Soon as the snow had disappear'd,
 And the larks' gay song we heard;
 Soon as from her icy bed
 The snow-drops came to peep and tread;
 Soon as the crocus flowers burst forth,
 Like tongues of fire out the earth;
 We ventured forth on busy wing
 To hail the first-born flowers of spring.
 To the brooklets, sparkling bright—
 First we take our airy flight,
 Where yellow catkins, bright as gold,
 Adorn the willow branches old;
 And alder wands her tassels gay,
 Scaving the speck'd trout away;
 The dog rose and the scented thorn
 The brooklet's rugged banks adorn;
 There the primrose, modest, mild,
 At the sun's warm kisses smil'd,
 Like an infant fondly press'd
 To its mother's hearing breast.

Next to Shirehill's summit high,
 Humming on our way, we fly;
 Whose rugged sides, so steep and stern,
 Are carpeted with graefel fern;
 And whose head, so broad and round,
 Is with stately timber crown'd,
 Queen of the woods, the lady lark,
 All robed in green in early March,
 A tall and graefel holy she—
 Bride of Scotland's dark fir tree;
 A Binehard husband, stern, severe,
 Scowling darkly all the year.
 There the birch, with silver bark,
 On which the lover carves his mark,
 With it, branches waving free,
 Hides the wild anemone;
 And the lime, with fragrant flowers,
 Invites us to his shady bowers,—
 Where bird and bee together sing
 A hymn of praise to Nature's King;
 Whose command to bee and man
 Is—Gather honey while you can.
 Thus to live, we do our best;
 And you, kind sir, must do the rest.
 Give us some food for getting storn,
 Then you'd have an early swarn:
 Roof our house with warm straw-hackle—
 Not broken pans, nor such vile tackle;
 Protect us from the thieving mouse,
 Nor let the moth gnaw at our house;
 Nor snail, nor earwig—mawling creatures!
 Nor soldier, with his ugly features,
 With hairy legs and goggle eyes,
 Ensnaring us like vulgar flies.
 Beware the tomtit—cunning fellow!
 The soldier—wasp, all streaked with yellow;
 Bad-conduct stripes they sure must be,
 For ne'er a goodly act did he!
 From foes like these protect our store,
 And may you prosper evermore.

HONEY HARVEST IN AUSTRALIA.

LARGE AND SMALL HIVES.

MR. JAMES DICKINSON, writing in the *Melbourne Argus*, says "For nearly half a century I have made the habits and management of the honey bee my study, and experience has convinced me that for economical purposes the use of a small hive is the most profitable—a conclusion which has the support of most writers upon this subject, but at variance with the opinions entertained in this part of the country, where large hives are almost universally used. I give the following facts illustrative of my theory:—

"On the 20th of October last I procured a swarm of bees which had been cast that day; this we will call No. 1. On the 13th of December it cast a swarm, No. 2; December 23 it swarmed again, No. 3; December 26, again, which swarm I lost, a neighbour being the fortunate recipient, No. 4. January 13 No. 2 swarmed, No. 5. February 20, No. 3 cast a swarm, which escaped to the bush, No. 6. March 5, No. 3 swarmed again, No. 7; March 14, No. 2 swarmed again, No. 8; and on the same day No. 5 swarmed, No. 9. February 14, I de-

prived No. 1 of 27 lbs. of honey. March 20, took 28 lbs. from No. 2, and the same day 25 lbs. from No. 5. March 25, deprived No. 3 of 21 lbs. April 10, No. 5 again of 26 lbs.; and lastly, on April 22, No. 8 of 20 lbs. March 20, Nos. 2 and 5 joined in one hive after deprivation; and on the 26th Nos. 1 and 3 did the same. To sum up; in six months I have procured 150 lbs. of honey and five good, strong, healthy hives of bees, with which to commence another season, from one swarm, besides having lost two swarms. I think the advocates for large hives cannot adduce a greater remuneration than this. The boxes I use are 9 inches by 10, by 15 inches; contents 1350 inches. The common gin-case is the smallest in general use here (I have seen hives three times this size), containing 2880 inches. Amazing as the fecundity of the queen bee is, she seldom has sufficient progeny whose united labours can fill this space in one season.

"In conclusion, I may state that the domestic bees which have escaped since their introduction are now so very numerous in and around the Plenty Ringers, that a couple of active, energetic 'bee-hunters' would be amply remunerated by following that vocation for three or four months each summer."

[Results such as are above described can, of course, only be obtained in an extraordinary honey-producing country: 1350 cubic inches is considered a full-sized bee-box in England. Bar-hives, 13 inches square by 9 inches deep (which is the extra size used by Mr. Woodbury for *Lagurians*), contain only 1394 cubic inches, after deducting the space occupied by comb-bars.]

HOW FAR DO BEES FLY?—The question is frequently asked, "How far do bees fly in search of honey?" There are instances in which they go three or four miles, when the weather is warm and no winds exist to obstruct their flight; but the average range of a family is in a radius of about three miles diameter. If we could place a hive of bees in the centre of a desert or sandy plain, three miles in diameter, I do not think that they would be able to gather honey enough to survive, even if a great supply were to exist at the usual reason, on the immediate borders of the said plain.—(*Genesee Farmer*.)

VARIETIES.

ENGLISH WINE.—The Romans introduced the Vine into Britain, and on their departure the ecclesiastics became the cultivators of the Grape and the manufacturers of wine. The great barons also made much wine for their own use. The Duke of Norfolk had a large vineyard at Arundel Castle, and had at one time sixty pipes of excellent burgundy in his cellar, Warner, the introducer of the Black Hamburg Grape, made wine from his vineyard at Rotherhithe. Roque did the same at Wallham Green. The last vineyard in England was that at Farnsbury, in Surrey, where we have seen the remains of the roots of the plants striving unsuccessfully to send up slender shoots under the grove of Scots Pines which now flourish on the spot, near to where the Portsmouth road is cut through the hill. After the death of the proprietor (the Hon. Charles Hamilton), a large sale of burgundy, claret, and champagne took place, and realised high prices, these wines being considered so excellent as to equal those of France, and this so recent as the latter end of the last century. Wine was made in all the monastic establishments upon a large scale, teetotalism being unknown to the ghostly fathers. Nevertheless wine was imported from France, to a considerable extent, at a very early period. At the installation of the Archbishop of York, in the reign of Edward IV., one hundred tuns of wine were drunk on the occasion. His predecessor is said to have used eighty tuns of claret yearly in his own house. Amongst the Barons there was no stint; the consumption of the Earl of Shrewsbury's establishment exceeded two tuns per month, and from the Northumberland household-book we learn that although the greatest economy was practised, the consumption was forty-two hogsheds per annum, perhaps ten times the quantity now used in the establishment of the head of the house of Percy.—(*Scottish Farmer*.)

NOVEL USE FOR BEEHIVE.—We have had brought under our notice this week a novel and by no means insignificant or uninteresting plan for blooming Hyacinths. It is simply this—A transverse section of about 3 inches or so of the upper portion of a Beehive is taken off with the crown attached; whereafter it is hollowed or scooped out, sufficiently to hold a Hyacinth

bulb; it is then suspended by a string of narrow coloured tape. The Hyacinth grows as in a glass, but in this case the stand grows also. As the Hyacinth progresses, so do the leaf-buds in the inverted crown of the Bee, and the little leaves of the brightest and most intense crimson, curve upwards closely round the root, continuing pretty now with the green of the daily developing leaves, and by-and-by with the blue, red, or white of the Hyacinth when in flower. Altogether the idea is a capital one, and the effect pretty and striking, as any one may observe who passing through Westminsterland Street will stop and look in at the window of Messrs. Toole and Company, where those cheap and pretty *jar-diarees* may be seen.—(*Dublin Agricultural Review*.)

THE COCOON-TREE.—A paper on this majestic tree and its uses, read by Pr. Hugh Cleghorn at a meeting of the Edinburgh Botanical Society appears in the Edinburgh "New Philosophical Journal." We give a few notes.—The genus *Coccoloba*, by far the most important of the Palm tribe, contains twelve species, of which the Cocoon-tree (*Coccoloba nucifera* of Linnaeus) is the most valuable. There are many varieties, five being indigenous to Ceylon. It is found all over the tropical part of the world, growing from 60 feet to 80 feet high. Its fruitfulness varies with the soil, and it seems partial to the seaboard. Possessed of a habitation darkened by a clump of Cocoon-trees, a Jak, and a Palmyra tree, a native of India is considered a landed proprietor. George Herbert truly says:—

"The Indian nut alone
Is clothing, meat and trencher, drink and can,
Bat, cable, sail, mast, needle—all in one."

The leaves are serviceable also for tethers, screens, baskets, and mats; the fibrous coating of the fruit forms a rope, and is used for stuffing mattresses; and the kernel furnishes a rich, clear oil. The tree is propagated by nuts, which, when planted thoroughly ripe about May, come up usually about November. The first leaf is single, and the plant is transplanted before it divides. The tree begins to bear in seven years; in fifteen years is in full bearing, producing about sixty or seventy nuts, and continues bearing from seventy to eighty years. Dr. Cleghorn describes the mode of extracting the toddy, and gives engravings showing a native equipped for the ascent, his apparatus, &c. When the spathe of the tree is ready to yield toddy may be known easily, by the chattering of birds, the crowding of insects, the dropping of the juice, and other unmistakable signs. In 1858, 2,508,869 Cocoon-trees were imported into the United Kingdom, and were almost all retained for home consumption. They are used instead of wedges to fill up the interstices between casks and packages in the cargoes of ships, so that the freight costs little. In the same year our imports of Cocoon-tree oil amounted to 197,788 cwt.

COCON-GRASS AS A REMEDY, AND AS FOOD.—An infusion of the Triton grasses, *Coccoloba*, in the proportion of one ounce of the dried and cut stem to a pint of water, and given in the course of the day, has been found by Mr. H. Thompson, of the University Hospital, to be very beneficial in irritable conditions of the bladder. According to him, it is important that the plant should be gathered in the spring, shortly before the leaves appear; the stem is then to be slowly dried without artificial heat, and cut into the requisite lengths for use. Professor Burnett, speaking of this grass, says, "The Coccoloba-grass of the farmers, which is here regarded as a noxious weed, is collected on the Continent as food for horses. Cattle of all kinds are fond of the underground shoots of this plant, which are sweet and wholesome. Sir Humphry Davy found them to contain nearly three times as much nutritious matter as the stalks and leaves; and it has been stated, on the authority of a French veterinary surgeon, that exhausted and worn-out horses are very speedily restored to strength and condition by giving them daily one or two handfuls of Coccoloba-grass, of 10 lbs. or 12 lbs. weight each, mixed with Carrots."—(*Dublin Agricultural Review*.)

OUR LETTER BOX.

METALLIC SUBSTANCE IN COAL (S. H.).—It is merely iron pyrites, sulphuret of iron, and where it abounds it has been employed for making green vitriol, sulphate of iron.

A FEW OF RECEIPTS FOR TRACING OUTLINES of either oil paintings, or drawings, or prints, or engravings, without any injury to them, upon any kind of paper which does not lose its colour after the process, appeared in the *Globe* newspaper some time since. It was by some preparation of benzoin. The process has been lost, and the writer of this would be most thankful to get the receipt again.

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last thirty-five years, the average highest and lowest temperatures of these days are 49.1° and 31.7° respectively. The greatest heat, 68°, occurred on the 9th in 1828; and the lowest cold, 7°, on the 10th in 1847. During the period 163 days were fine, and on 80 rain fell.

THE PANNELLING SYSTEM OF PLANTING LONG FLOWER-BORDERS.

YOUR valuable Journal has long been the leading and most able expositor of all matters connected with modern flower gardening, I have thought that a few lines illustrative of a system which I have carried out here for several years in planting long borders might prove interesting to some of your readers. The effect produced by what is now very generally known in Scotland as the panel system of planting, is admitted to be much more striking in many situations than ribboning. However the merits of this style

of planting may be estimated comparatively, it can never fail to form a most pleasing variety when well executed; and where long and wide borders form a prominent feature, it is especially suitable. The striking effect and variety of design which can be produced with comparatively few varieties of plants by panel planting are not easily brought out by any other system that I am acquainted with.

Probably the easiest and most simple way of conveying in words a correct idea of this mode of decoration will be to name the material with which a few of our most telling borders have been planted, and state the exact order in which the operation of planting was carried out.

1st (A border 17 feet wide). A line was stretched along the centre of the border, and at every 14 feet a stake was fixed in the ground, and from each stake, with a radius of 3 feet, a circle was described. On every alternate circle, 6 feet in diameter, a mound of earth was raised to the height of 3 feet above the ground level, and tapering to a diameter of 2 feet at the top. Into the centre of the mound a socket for a vase was fixed, and on this socket a vase placed, and filled with soil. A large specimen of Kollisson's Unique Geranium was planted into every vase, and staked into a pyramid. The mounds of earth were then planted with Tom Thumb Geraniums, and the surface of the earth paved over with round blue bullets from the sea-beach, to prevent heavy rains from washing down the soil, and drought from drying it rapidly, while the water, passing through the vases and sockets, kept the centre of the mounds where the roots penetrated safe against the trials of a dry season. Every alternate circle was then planted on the flat with yellow Calceolarea. Round this circle of yellow was planted an oval of Purple King Verbena—the oval stretching along the border, and intended to give weight to the purple in passing the eye along the border. A single line of Purple King Verbena was next planted along the front a foot from the Box, and another line in the same position at the back of the border. The whole vacant spaces between each circle and mound and between these two

margin lines of purple were filled up with Mangles' Variegated Geranium, giving a groundwork of pink flowers and variegated foliage, with mounds of scarlet tipped with purple, alternating with flat panels of yellow surrounded with ovals of purple, to prevent the yellow and pink from neutralising one another. The whole margined with a single line of purple, the back row being of Humea elegans, alternating with white Dahlia Alba Floribunda; the bronzy waves of Humea bringing out the white Dahlia, and the Dahlia bringing out well the line of purple.

The following sketch, if it be worth inserting, will show at a glance the above arrangement.

- A Mound of Tom Thumb Geranium, surmounted with a pyramid of Kollisson's Unique Geranium.
- B Circle of yellow Calceolarea, surrounded with oval of Purple King Verbena.
- C Circle of yellow Calceolarea, surrounded with oval of Purple King Verbena.
- D and E Lines of Purple King Verbena.
- F Back row of Humea elegans and dwarf white Dahlia alternately.
- G Box-edging.
- H Groundwork of Mangles' Variegated Geranium.

2nd. In 1860 the preceding border was planted with Tom Thumb for groundwork, with alternate panels, on the flat, of yellow Calceolarea and Purple King; each panel of yellow having a large specimen of Humea elegans in its centre; margin lines were of Variegated Geraniums; the back line of all being of Hollyhocks, 18 inches apart, trained with a single stem, and topped to the same height. This was a most telling border.

3rd. Two borders, in 1859, with groundwork of Verbena venosa. Alternate panels of yellow Calceolarea and Scarlet Geranium—front margin line Variegated Alyssum; back margin of Cineraria maritima, backed up with Prince Arthur Dahlia. This was very effective.

4th. Groundwork of Variegated Alyssum, with alternate panels of Purple Verbena and Brilliant Geranium. Margin lines of blue Lobelia.

5th. Groundwork of blue Lobelia speciosa, with mounds of Scarlet Geranium alternating with panels, on the flat, of Golden Chain. Margin lines Cerastium tomentosum.

6th. Groundwork of Lobelia speciosa, with panels of Mangles' Variegated Geranium and Brilliant alternately. In the centre of each panel of Mangles' Geranium was a neat slender specimen of Irish Yew about the size of a gentleman's umbrella, and round which the Geranium was trained cone-shaped to within 18 inches of the top of the Yew. Margin lines of Golden Chain. This was very much admired by the ladies.

7th. Groundwork of Purple King Verbena, with panels of yellow Calceolarea and Scarlet Geranium alternately. In the centre of yellow, a very small neat Irish Yew. Margin lines, Flower of the Day Geranium. On getting

the first sight of this border a lady exclaimed, "Surely the hand of an enchanter has been here!"

8th, Groundwork of *Lobelia speciosa*, with alternate panels of *Centaurea rugosina* (a glorious plant) and Brilliant Geranium. In the centre of each panel of *Centaurea* an Irish Yew about 2½ feet high. Margin lines of Golden Chain.

9th, Groundwork of Brilliant Geranium, with panels of *Perilla* and yellow *Calceolaria*; with margins of *Alyssum*, with backing of *Tritoma* variegata.

The above will serve as examples of this style of planting. To bring out the system well it requires a long and wide border. Here there are five borders particularly suitable for it, the narrowest being 12 feet wide, in which the panels are 4 feet in diameter. My own favourite border is that first described. No. 5 was also particularly fine. No. 6 looked particularly well viewed from an elevated position, and the panels looked like something set upon a polished surface framed in gold: probably this was the most chaste. No. 4 was characterised by "unassuming loveliness."

The method which I adopt with *Cerastium tomentosum* when used for long marginal lines may probably be useful to some of your readers. In March, small cuttings are taken and dibbed in (without being made into cuttings in the usual way) about 3 inches apart along the line, leaving just the points of the bits above the ground. When the line is lifted the row of cuttings looks just like a chalk mark. They are watered, and in a short time they root, and begin to grow; and, managed thus, they make the most uniform and beautiful lines I have ever seen of it, and will grow to 2 feet wide, if allowed, by the middle of July.—D. THOMSON, *Archerfield Gardens*.

USE OF HUMUS IN A SOIL—CAUSE OF VARIEGATED LEAVES.

If you do not recollect one of the ideas which led to the discussion on the disease or no disease of variegated plants last summer, you will not profit so much as you ought from the application which must be made, sooner or later, of the present rising of the sap by the forces of vitality and warmth, or rather of the discussion about that movement.

The "OLD SHOWMAN," whose views led to that passage of arms said, among other things, that the cause of the convertibility of green leaves to variegated foliage by manual process, might be owing to the decomposition of water or some chemical process like it, and one of those who took part in the discussion seemed to doubt the possibility of plants, or the roots of plants, being able to decompose water.

My copy of the Journal is in the hands of the bookbinder, so that I must write from memory; but I well recollect the impression made on my mind from the doubt thus cast by a practical observer on one of the clearest points in the chemistry of vegetables. Also that a clear knowledge of the effect of the decomposition of water on the vegetable fibre would, or should, have led the "OLD SHOWMAN" to exactly the opposite conclusion.

As long as the now-explored doctrine of humus and humic acid held sway, and more particularly since Sir Humphry Davy lent the weight of his powerful authority to it, you could not wonder that some men might be led away with such crude ideas of vegetable chemistry as that humic acid, as it was termed, might change green to white or white to green, or all the colour of all the leaves to the most intense green when properly applied, or might be so administered as to do just the reverse; for at the time alluded to, men's minds in our calling were bent, as it were, on the reality of the power of humus to effect any result which a gardener wished, if he only used it in the particular way for that very purpose. And one of the ways might certainly be to convert a green leaf to the variegated form—say by some application or preparation with the acid of humus. But the fact has been clearly proved and explained; first by Edwards and Colin in 1838, and lastly by Liebig himself, that water is decomposed by the roots and parts of plants, and that without the decomposition of water all the humus in all the gardens is of no more use to plants than gunpowder and shot; in short, that the roots of plants have no power at all to get the goodness, or any good, out of humus unless water is decomposed.

Now, to explain as we go. Humus is the black remains of all dead vegetable or animal matters after the smell is all gone, and

the fibre and substance reduced to mould or powder. It is this humus which makes so much of the cultivated lands look black, or like black mould; and this humus was, till recently, believed by all gardeners to have been the very life and soul of the food of plants, either as the cream of all vegetable mould, or as dissolved in water like so much guano. It is now, however, a clear point that all this was entirely a practical mistake—that neither in solution nor in the solid form can humus be of more use to plants than pebbles from the seashore.

So you see we were all of us wrong, not only on the power and action of roots, but of how they fed on what we gave them. Yet our practice all the while was quite true, so to speak. We said, in effect, that the very great difference between the healthy looks of plants luxuriating in humus, or the essence of black mould, and those on ground in which little or no humus existed, were so manifest as to require no arguments to prove this. "Very good," says chemistry, "you gardeners are good fellows, and choose good ground for what you do; but you are out of the ground altogether in explaining the goodness of humus. As you see it, or as you apply it, dry and wet, or soluble, as you take it to be it is, and cannot possibly be of the smallest use to any plant under the sun." This was worse than a thunderbolt to all our pride of "principles." "Why, you old chemical quack," we retorted, "some of us know more of humus and humic action than is known yet in your crucibles; we can even change the colour of the leaves with humic acid, and that is more than most chemists have ever thought of hitherto, let alone the aspiring to do the deed as we can."

So far for the explanation of what humus is, and what it has been thought to do for us gardeners. Now, let me explain next what is meant by decomposition of water; for unless young people and old folks know the meaning of the words we make use of, how can they get at the meaning of what we write and say? What is more common from our pens and tongues than the word compost—so much sand, such a quantity of leaf mould, and a certain proportion of peat and loam—these put together make a compost. Now, suppose you wanted to undo this compost, to get out all the sand by itself, the leaf mould without peat or common mould with it, and the peat freely separated from the loam. No gardener could do that you know, but chemistry could do it; and the old man would tell you after it was done that he merely decomposed your compost. You composed it and he decomposed it, or undid it into the separate parts of which you made it. But what has that to do with the decomposition of water, and the watery looks of variegated leaves? Why, you must know that water is not a simple drink after all, as they say it is, more than tea or coffee. But let us take the coffee to explain it by. There are the water, the milk, and the dark brown, or the humus of the coffee as one might say, all mixed, and that is coffee composed of the three things—a liquid compost in fact—who can decompose it, or get out the sugar, the coffee brown, and the water, each to be clear of the other two? You or I could not do it; but chemistry could, and would call it decomposing coffee.

Well, pure water is composed of two things and half a thing, but say two things, as sugar and water were in the coffee; and the roots of plants were but recently discovered to have the chemical power to decompose water, just as the chemist decomposed the compost or the coffee; and one of the parts of which water is composed would be poison to us without the other part; and it is this poisonous part (Hydrogen) which humus supplies to the soil and to the water in the soil on which roots feed; and the roots, after decomposing the black water or from the humus, take only the feeding part out of that which would be poison to us; the other part is let off free as far as roots are concerned.

This hydrogen, or portion of water poisonous to animals, it is from which some of the products of plants are exclusively obtained—as indiarubber, gutta percha, wax, and volatile oils; besides being one of the great elements from which the wood of plants is made by the leaves, and leaves make the rest of the wood from another kind of poisonous matter floating in the air and which is in reality part of it, so that the heartwood of the Oak, is, by the most mysterious process of Nature, made by the roots and leaves of plants from sheer stinks and smells, which no one can see or feel, and which would annihilate the whole of the animal kingdom were it not kept within due bounds by the requirements of the vegetable kingdom.

Now, what could the decomposition of water give out to the roots of Geraniums to cause the leaves to become variegated?

Liebig says the decomposition of water is necessary only to make plants healthy; and some of us imagine variegation is an unhealthy condition, so that that condition cannot be ascribed to that natural process by which the roots of plants decompose water.

But there is another point—an old one it is true, on which Liebig lays the force of his approbation, but with which I totally disagree—I mean the notion that because plants are known to feed they must necessarily excrete refuse matter as animals do. Animals do, certainly; for you cannot conceive such a thing as food without some refuse; but plants do not feed as animals do, neither can they evacuate refuse as we do—at least, not by imparting to the soil their excrements through their roots.

The leaf is the only organ in the vegetable kingdom through which the refuse of the food of a plant can by any possibility pass out of the system, and as long as there is a sufficient leaf action for that process, it is constantly going on. But there may be a thousand things, at times, to hinder the leaf from going thoroughly through the process of giving off the whole of the excrements, and one thing out of that thousand will cause some derangement in the leaf. The leaf imparts the consequence of its derangement, so to speak, to the parts which it is its office more immediately to feed and increase; that consequence may be one thing, or one affection, at one time, according to the time of the season, and another thing at a later or earlier period. In one of the stages of the affection caused by some hitch in the stomach, the leaf itself being that organ in plants, it transmits, or the leaf imparts, the affection to the next generation through its power in providing the proper food for the seed; but in this instance the food is not quite so proper to the seed as it should be through that affection in the leaf. The consequence is, the seedling from that seed so affected will not come so true to the kind as if it had been fed by a healthy or more healthy leaf or leaves. The consequence is, a seedling possessing features differing from the type, and one of the features may be a more soft and succulent leaf, or it may be a variegated leaf.

There is nothing known to me from which I could conscientiously infer variegation in leaves or parts of plants to arise, except through some such process affecting the seed in the first instance. All the turns that all plants take are, no doubt, referable to some chemical process, and so is this of variegation. But all the chemistry in the world is not sufficient of itself to make a single leaf or a blade of grass, or alter the form or colour of a leaf in such a manner as can be transmitted through successive generations of propagation, so to speak. I fully admit, figuratively, that new plants are created every year of our lives by the agency of man, but I cannot conceive such a power as would, or could, alter any plant or leaf from the state it was in on coming into existence.

The real cause of variegation none of us knew, and those who assume a knowledge of it by referring it to some state of disease, do so merely to avoid a very difficult problem. It may be from some diseased condition, but evidences are quite as numerous and as strong against that view of the question as in favour of it. All that I hold is, that spots in this form are not the result of accident, and that you cannot imitate them by manual process; also, that it is not the diseased condition of the parents that is so transmitted, for the most healthy parents in the garden are just as liable to have a variegated offspring as those in the last stages of decay. Then, if variegation cannot be made by man or come into being by seed, it must be caused as many maintain with me, through some chemical change that is unusual in the food of the parent plants, or in their own organs when converting all that is foul and filthy under them and above them into the products of their own kingdom.

In conclusion, my last experiment is more puzzling to me than most I have had in hand on variegation. In 1859 and in 1860-61, I planted twelve of the healthiest plants I had of the Crystal Palace Scarlet Geranium in the same spot and the very same soil. I had so many flowers of the best brass of each plant dusted with the pollen of one of my strong healthy seedlings with plain green leaves. All the seedlings from them in 1859-60 were as plain and as green as those of the parents; but from last season I have now hardly a seedling of the very same cross, and under exactly similar circumstances, with a clear green leaf free from white specks and blotches. Whatever may have been the cause, it affected twelve plants just alike.

D. BEATON.

RESTORING VARIEGATION IN A LAUREL.

Is there any method of causing the variegated Laurel (which is inclined to turn green) to recover its variegation? The shrub from which the enclosed leaves were taken was some years ago beautifully variegated, but is now chiefly green.

[To preserve variegation in common Laurels, the same rule as for promoting fruitfulness in fruit trees should be applied. If a Pear, or a Peach, or a variegated Laurel is highly fed, the high feeding tends too much to the increase of the growth for fruitfulness or for variegation. The leaves of your Laurel are yet very beautiful, and if you were to transplant it this spring and put it into a poorer soil, and more in the shade, they would very likely become more fully variegated than before.]

SCHEDULE OF THE ROYAL HORTICULTURAL SOCIETY, 1862.

It seems a very ungracious thing, when a friend has exhausted his ingenuity in setting before you and your friends an entertainment which he imagines is perfect in all its parts, to suggest that he has forgotten the orange biscuits with the dessert, or that there was more than a *souçon* of Onions in the *enclette aux fines herbes*; and yet one finds oneself just in that position with the schedule of the Royal Horticultural Society.

It is hard not to express unqualified praise when the various courses, beginning with the minor shows on to the great Grand and Saturnalia, are so liberally set out—when the sum total of the prizes offered is £2146—when fresh-water aquaria, and window-boxes, and wax Turnips, and anything that can add variety to the exhibition or be pressed into the service (much in the same way that I recollect a medical book society thought it enough, if a book were written by a medical man, to include it in its lists), receive prizes—yet as a friend to its welfare and desirous of its efficiency, I cannot give it unqualified praise; and in the grumbling remarks that I now make I am not only expressing my own sentiments, but those of many practical men. And when as a florist I object to the manner in which we have been slighted, I do not intend to suppose that there was any deliberate attempt to “snub” us.

I must suppose that the Council, and the Exhibition Committee, and the Secretary, are all honourable men desirous of accommodating all parties, and that what we have to complain of arises rather from underrating the value of the flowers which we especially consider worthy of their notice. But I beg to submit a few reasons to show that our complaints are well grounded.

The exclusion of a large number of florists' flowers from the schedule of 1861 attracted the attention of several members of the Floral Committee; and a resolution was passed and forwarded to the Council, naming the omissions, and suggesting their insertion in that for 1862. A courteous reply was returned, saying they must be considered in the schedule for 1862. But there was a hitch somewhere: either it was not reported in the proper quarter, or else it was forgotten, or else ———. However, it is not worth while suggesting any more reasons, but there is the simple fact.

Now, when the Floral Committee, composed as it is supposed to be of the most practical men that can be got together, unanimously records its opinion, surely the least they can expect is that due attention be paid to their recommendations. I am not disposed to call it, as some did, “quiet insolence;” but the very strong feeling that such an expression indicates, combined with that which I also heard—“we shall have to resign *en masse!*” shows that there is a leaven at work in a body, let us remember, composed of gentlemen who give their time and labours gratuitously, which it will hardly be well to disregard.

Secondly, It must be recollected that the more popular direction given to the management of the Horticultural Society led to the abandonment of the National Floricultural, the National Rose and Pomologies Societies, and that therefore it would be naturally expected that those subjects which were their especial province should be thoroughly provided for. As a general rule they are; but there seems an arbitrariness in the selection of some and the rejection of others which is unaccountable. Why should Tulips be placed in the schedule in May, and Pinks be excluded in June? Why should Carnations and Picotees (which Dr. Lindley prefers to the Dahlia) be absent from the July Show, and £52 given to foliaged plants, including

the Caladiums and Begonias? It may put money into the pocket of some "eminent nurserymen," and fill up a large space; but these are not reasons sufficient to satisfy questioners upon the point.

Thirdly, I fearlessly appeal to the general interest that they excite as in itself a sufficient reason for their being more considered than they are. I know they are the abomination of botanists; but we may be thankful that all lovers of flowers are not botanists, or we should be overwhelmed with all sorts of rubbish. But the question is, What do the public in general think of them? Why, I read a complaint the other day in one of the gardening papers, that people examined them so closely and stayed so long over them that the thoroughfare was obstructed. May I ask whether that was the case with the tree Ferns, or the Dracenas, or the Caladiums? I grow not. As a florist I may be, perhaps, too much inclined to look favourably on my pets; but I do believe that for one grower of tree Ferns there are a thousand growers of Roses and a hundred of Carnations and Picotees, and surely that which is the favourite in cultivation ought to be considered in an exhibition.

I know it may be said in answer to this, "We cannot take in everything. We have expended so much, and we must place a limit somewhere." Well, let it be so; but I think I have pointed out where a curtailment might have been made without any great harm. Why not have included the Begonias in the fine-leaved plants? And surely it is as much within the province of the Royal Horticultural Society to encourage the production of a good stand of Pinks and Ranunculus as that of a wax Cabbage, or the arrangement of a fresh-water aquarium with its tadpoles and water-nests. Besides, I suppose £30 would cover pretty well the requirements we make; and it is hardly worth the Council's while for that sum to make grumblers of a large body of persons, especially as it arises from the non-carrying out of a proposition of which they have approved.

There are some other points about which, as the fit is on me, I may as well say a few words. Did not my friend Mr. Hole, in the most chivalrous manner, resign his laurels as the originator of the National Rose Show to the Horticultural Society? They acknowledged that last year; but not only this year do they omit all mention of his name, but they fix their show at the suggestion of one grower (my worthy friend the Vicar of Rushton), on the 26th of June, when northern growers will be unable to exhibit, unless the season be very different to what it has been—and as a result he is now endeavouring to organise a midland and northern show; and thus probably our hopes of a national Rose show will be centred in the Crystal Palace Company, who are wiser than to do such things. And why, may it be asked, when £128 for Roses are most liberally given on the 26th of June, is there not one single prize offered on the 2nd July, when they will be unquestionably in finer condition? Such things pass the comprehension of our philosophy.

Is it too late to say a word about the site of the exhibition? We had last year a taste of what the conservatory is—destructive to the well-being of cut flowers and very inconvenient. What it will be this year, with the large accession of visitors we may expect in London from the opening of the Great Exhibition, we hardly dare to think. But could not the exhibition be under canvas at the lower portion of the garden?

Some of the grievances thus complained of may be remedied, and I feel sure that whatever Mr. Eyl's can do consistently with his position to forward our views he will; but he has not the power, although he may have the will. We must try and apply a little gentle pressure where such will most tell; and I feel sure that if two members of the Floral and Fruit Committees were added to the Exhibition Committee it would make matters right, and prevent these serious blunders in future.—D., *Doct.*

WORSLEY HALL, NEAR MANCHESTER.

THE SEAT OF THE EARL OF ELLESMERE.

EFFECTS OF THE SEVERE WINTER OF 1861.

THOUGH the greater part of the extensive pleasure grounds at this place are elevated considerably above a flat district to the south, yet many evergreens suffered severely on the night of the ever-memorable 24th of December, 1860, more especially the common Laurels, which were all killed down to the ground. Mr. Davidson, the intelligent gardener, thought it advisable, however, to leave them standing to see whether they would shoot out again. I saw them on the 20th of February last, and

observed that nearly all of them had this last summer shot out at the base strongly, some having made shoots 2 feet high. Men were at work sawing off the dead tops, which made excellent pea-roads. In two or three years they will be dense bushes again. The young shoots have not suffered at all from the frosts of this winter.

Portugal Laurels.—In the lower parts of the grounds these have some of the branches destroyed, but the living branches have grown well since. Others in more elevated positions have not a twig or a leaf injured. A long row of bushes 8 feet or 10 feet high, on a level below the far-famed flower-garden are only partially injured, though growing on a strong clay. The lofty terraces above them, perhaps, have been a means of protecting them, and also the full exposure to the south has caused them to make short shoots early, the wood of which became solidified and well ripened before the severe frost set in.

Rhododendrons.—The pleasure grounds here are plentifully stocked with large specimens of this fine evergreen shrub. They are not injured in the least, though the greater part of them are hybrids of the Catawbiens class. This summer has been a favourable one for them, and the consequence is, they are almost universally well furnished with blossom-buds. They will make a splendid display this year.

Roses.—Some old standards and old sorts have stood the frosts well, but many, if not all, in the lower parts were killed. Even Roses on their own roots suffered severely, though they have pushed out strongly. There is a Rose garden in a very high position; all the shoots that were pegged down to the ground escaped, but such as were trained upright to a wire trellis all died down to the ground; but this summer most of them have made very strong shoots, which have completely clothed anew the trellis. The shoots are now alive to the very tops, and are as green and healthy as possible. In fact, some are nearly in leaf, so favoured are they this, comparatively speaking, mild winter.

Araucaria imbricata.—On each side of the long walk leading down the pleasure ground through an old wood to the kitchen garden, there was planted some eight or ten years ago a somewhat irregular avenue of Araucarias. They were planted on the level surface without any particular care, and have grown freely. The hard winter has affected them variously. Some that were fully exposed to the wind are I fear quite dead; others partially sheltered have some of their lower branches quite killed; others have during the past summer made some small growths, and many of their tops are green and healthy. I am glad, however, to record that there are a considerable number that have borne the battle with the frost and the breeze unscathed, the very lowest branches being quite green and healthy. Nearly all those that have escaped uninjured are surrounded with low Rhododendrons, which, as Mr. Davidson justly observed, have no doubt kept the frost from injuring the main stems, and also protected the roots in a great measure. It is evident there are some seedling plants of Araucaria that are more hardy than others.

Other Coniferous Trees.—Of these there are not many species growing here. I observed the *Dodders* were partially injured; *Pinus austriaca* has stood well, as also *Pinus excelsa*, and *Pinus Cembra*; *Abies nigra*, a fine specimen, quite safe; *Wellingtonia gigantea*—when Her Majesty our Gracious Queen visited Worsley two or three years ago, she planted as a commemoration of her visit, a fine specimen of this most magnificent denizen of California. It has grown well and stood the winters uninjured. From all that I have observed and heard, I am convinced that this fine timber tree is as hardy, if not harder, than any other foreign evergreen coniferous tree ever imported into this country. Should this opinion be correct, the next generation may expect to be able to plant it largely for timber purposes with every prospect of success.

Irish Yews.—On the terraces adjoining the large flower garden this compact-growing tree has been planted rather numerously, partly for the purpose of breaking the uniform level, and partly to give a variety of colour. I observed several of the top shoots with red. This was accounted for on the ground of the thinness and poverty of the soil, and that this is the true reason is exemplified by some specimens that had been removed into a deep rich soil in the kitchen garden, and have there made strong healthy shoots to the highest points. A good watering occasionally with guano water would, I have no doubt, have a good effect on these Yews on the terraces.

As I remarked before in the pages of this Journal, there is a

large sheet of water in the level below the flower garden. In the centre of this lake there is a large island, and on that island Mr. Davidson is busy now forming what will be a most extraordinary subterraneous grotto of a circular form, with many winding covered entrances through rockwork to it. It is so contrived that open spaces facing the water form half-circular seats. These in a hot summer day will be, after a long walk, very cool, pleasant, refreshing, resting-places. In other parts of the lake, on the land side, there are formed a kind of grottoes for the water fowls to enter and breed in and rear their young.

Directly facing the central large grotto, the Earl has had a long avenue cut through the ancient wood to the walk before referred to, as connecting the pleasure ground and the kitchen gardens. A gravel walk is being formed through this avenue, and large evergreens—such as Yews, Rhododendrons, tree Box, &c., planted on each side. Standing at the end next the connecting-walk, the long vista through the forest terminating with the lake, and across it the grotto will be seen. When completed this will be a very interesting and beautiful view. These extensive alterations employ a considerable number of hands, which is one of the blessings that a wealthy nobleman has in his power to bestow upon the needy poor, and no one is more ready to make this judicious use of his abundance than the owner of this fine place. To give a poor man labour is far better than to give him charity; the former renders him in a measure independent and happy; the latter, idle, careless, and miserable.

From the pleasure ground I transferred myself to the extensive kitchen gardens. Here every part is in a state of progress. Pine Apples in their various stages, some ripe, others swelling, some fruits just peeping up through the leaves. Succession plants advancing and being potted, and the nursing stock healthy. The whole with not an insect on them that I could spy out. Cucumbers bearing, Mushrooms springing up abundantly, Vines the first crop as large as peas, Peaches just setting, and others coming into blossom. Out of doors, showing how warm the weather has been, I observed Apricot blossoms very nearly expanded, although Errington's idea of retarding had been practised by keeping the trees a distance from the walls. Pears and Apples this year are well set with blossom-buds—a rather unusual thing in this moist climate and low situation.

Here I observed a novel kind of shelter for Roses and other half-hardy things. It is, in fact, a tent in the form of a half-span-roof, covered with Britain's threefold cotton-netting. Mr. Davidson speaks very favourably of it. I noted the Rose trees were looking well and in full leaf. Strawberry plants in pots were growing, and Chrysanthemums progressing almost too fast. The half-hardy Pentstemons are kept under it, and were as fresh and lively as if it were September instead of February. Many species of British and exotic hardy Ferns are in this net house and are very healthy. I do think a house of this kind, covered with this kind of net which is strong and lasting, would be a useful adjunct in every garden.

The stock of bedding-out plants here is really enormous, and the whole are looking remarkably fresh and green. I wish those who doubt the fitness of *Gazania splendens* saw the immense lot of it grown here. Last summer it bloomed most profusely and was generally admired. I must, however, conclude these few brief desultory remarks on the gardens at Worsley, as my allotted space is full; but I may have more to say about other matters connected with the flower garden at a future opportunity.—T. APPLEBY.

HOW TO TREAT VARIEGATED BEGONIAS.

In the latter part of March turn the plants out of their pots, shake most of the old soil off, and cut away all unsightly leaves from them. Pot them into clean, well-crooked pots as small as you can get them into comfortably. The soil to use is a mixture of one part of strong fibrous loam, peat one part, silver sand one part, and a little charcoal broken rather small.

After potting plunge them into a sweet bottom heat of about 70°, keeping them close for a few days. They must be kept shaded from the sun, as its rays soon burn the leaves.

About the middle of April they will have filled the pots with roots, if all has gone on right. Then mix a compost for them as before, with an addition of a little rotten dung about one part. Warm it in one of the houses or elsewhere, so that the plants may receive no check from potting. Then place them back again for a fortnight; from thence take them into the stove.

By that time they will begin to look well, and will make handsome plants.

At the beginning of June they will bear the temperature and light of the conservatory, if they are shaded, and may remain there for about two months, excepting some of the very tender sorts, these I keep in the stove. Towards October they will not want so much water, give them only just enough to keep them from flagging; thin; place them then in the coolest end of the house. They will require but very little water in the winter months.—A CONSTANT SUBSCRIBER.

[We shall be very glad to hear from you again as you obligingly offer.—EDS. J. OF H.]

NOTES ON VEGETABLE CULTIVATION.

(Continued from page 433.)

BEANS, SCARLET RUNNERS AND DWARF KIDNEY.—The latter class presents a greater variety, but they may easily be reduced. The Early Dun, Liver-coloured, and Negro for general crop, and the Mohawk for forcing will be found to answer very well; but other names might represent these and answer the same end. Natives of a warmer climate, they like a warm dry soil, and must not be planted too soon. The middle of April is soon enough in a general way in most places about London, and a little later than that in cold late places; and occasional sowing up to the end of June will carry on the succession. This useful vegetable also forces better than anything I know of, and may be had at all times where there is accommodation to force it. Here we have had a supply since the middle of December by sowing four or five Beans in a three-inch pot in heat, and after these are up with two rows' leaves they are transferred to an eight-inch pot, the ball being broken a little to allow the plants to spread; small twigs support the tender growth, and, being near the glass they bear well. In the open ground they ought to have a sunny exposed place, and they will amply reward any care that may be taken of them. The Scarlet Runners are more robust, and at the same time more prolific, continuing bearing until frost puts an end to their existence; and, as a cottage plant, it is second to few for general usefulness. The first week in May is soon enough to sow the first batch, and they may be sown from then to the middle of June; but the bearing properties of the plant are such that it very often happens the first rows continue in bearing to the last; slender poles about 8 feet or 9 feet high are best for them, and the rows ought to be at least 6 feet apart. The bearing properties of the plant are much enhanced by not allowing any pods to remain on to ripen; in other respects the plant requires no particular attention after it is once started to climb the poles.

BROCCOLI.—This extensive family deserves more than a passing notice, as it forms such an important item in the general bill of fare; heads of Broccoli in one form or another being expected all the year when Cauliflower falls short—in fact, the two vegetables approach so near each other in appearance and utility that the distinction between them is difficult to explain, and some of the varieties of Broccoli resembling Cauliflower are often cultivated for summer use; indeed I have heard an experienced gardener say that he has cut Walerchen Broccoli all the year round. Be this as it may, certain it is that in mild seasons the winter supply of this useful product is more plentiful and regular than in severe winters—in fact, certainly in a few favoured localities it cannot be had with a certainty all the year round: the best situation for it is near the coast, and especially that part where there is least frost, as the south and south-western coast. The names given to some varieties plainly indicate the favoured spots of its growth, Penzance and Portsmouth, the frosts being less severe on the coasts; and this vegetable not objecting to the occasional saline spray that finds its way inland some little distance during a storm, it is made to thrive and grow at times when similar plants in the interior are killed outright by the severe frost. But, as the choice of such situations is confined to a few, the ordinary cultivation inland will be treated of.

For distinction it is better to divide the Broccoli family into classes. No. 1 being for autumn and early winter, it might consist of Early Purple and White Cape, with one or two others as Imperial. No. 2 is supposed for midwinter use, and may consist of Walerchen, Snow's Winter, White Sprouting, Knight's Protecting, and one or two others. No. 3 being the late spring kinds, represented by the Portsmouth a large kind, Wilcove an intermediate variety, and the small dwarf varieties called

Miller's Dwarf or Russian; the latter being smaller may be planted closer, they are very hardy, but they all come in together. There are several other varieties in this section, as the Briststone, Emperor, Incomparable, and others; but they differ but little from each other. A late purple is, however, useful, and in sowing it is better to have small varieties in order that if one fall another may come on; this is more especially advisable when the seed cannot be depended on. Sow the late kinds about the third week in April; but the Early Cape need not be sown until the 1st of June; the Waleheren and Snow's Winter about midway between these two periods. If the weather be dry cover the seed-beds with boghe or something of that kind to shade them a little, taking care that the birds do not carry the seeds away, which they are fond of doing; plant out as occasions offer. Generally this crop is made to succeed some other, as early Potatoes, Peas, or such like, and the young plants are sometimes planted between rows of Peas while the latter are standing. Where ground is scarce this is excusable and recommendable, taking care in gathering the Peas not to injure the Broccoli plants. About 2 feet apart each way will do for the Cape and medium-sized growing kinds; but the Southampton and large spring varieties may be wider, while Miller's Dwarf may be closer. The same place as recommended for Broccoli, planting in shallow drills, is advised for this plant, and earthing-up the same. On the approach of severe weather it is a very good plan to lay some of the late kinds just coming into use down on one side, by taking a small spit of earth out from the root on one side and bending the plant down that way, laying the spit on the other side; it is best to point them to the west as being the direction they are least likely to take harm, the centre or head being protected by the overlying leaves.

Cauliflower.—This is for the summer what Broccoli is for the winter; and, if care be taken to plant a few Cauliflower plants in an early situation, and a few of the latest kinds of Broccoli in the latest places, it is likely the latter will carry on the supply until the former come into use. Usually there is about a week blank between the two: this, however, may be got over by careful management as above. Cauliflowers afford few varieties; but sometimes a spurious kind gets into cultivation. But as every one knows the genuine article it need not be described here. Sow on the 1st of September for the first crop, and as early in the spring as can be done for the second. Succeeding crops may be sown up to the end of June. Plant out on good ground, as this plant is a greedy liver; and is benefited by occasional waterings with liquid manure. The young plants kept over the winter must have some protection either of glass or something as a substitute for it; sometimes, however, they will stand mild winters unprotected, but it is better to have a few under shelter lest an unusually severe winter set in; plant 2½ feet apart each way, on ground that is deep, rich, and open. Some of the summer crops may be on a north border in the very hot weather; but, generally, this crop does best in the open square.

Cabbages.—To the cottager this is second to no vegetable that is grown; neither is it less thought of by the more wealthy, Cabbage and Cabbage sprouts being supposed to be forthcoming at least nine months of the year. As a vegetable the Cabbage has certainly improved the last twenty years: the liability of the plant to run to seed in April has in a certain measure been got over, and some of the best varieties can now be forwarded somewhat earlier the preceding autumn on that account. About the 20th of July is soon enough to sow the first batch, and again the 1st and 12th of August; and, as some uncertainty hangs over the first lot, it is best not to plant too many of that sowing. A second sowing may be made early in spring, and another after that if required; but, generally speaking, the sprouts from the first plantation serve the after season. The varieties are numerous enough; but Barnes' Dwarf, Blenheim, and Imperial, are all good early kinds; while the Nonpareil and Enfield Market are also good, but a little later. The Red pickling Cabbage may also be mentioned here: this need not be sown until spring, as likewise may the Braganza or Couve Tronchuda, a loose-growing plant, the ribs of the leaves being the part eaten; it is like the Red and Drumhead (or Scotch), an autumn Cabbage, and they all require more room than the ordinary spring or summer Cabbage; but the requirements of the whole are much the same as that of the Broccoli, Cauliflower, &c. The instructions there given as to planting, applying also to this. J. ROSSON.

(To be continued.)

GLADIOLI ATTACKED BY WIREWORKS.

My varieties of *Gladioli gandavensis* did worse than usual last year. The bloom of most of them was destroyed by thrips; but, besides these, the leaves of many turned brown and died off before coming to maturity. The bulbs of some of these had been eaten into, I suspect by wireworm, but I am not sure whether this was the result or the cause of unhealthiness, as the more weak-growing kinds were generally attacked. Will a mixture of lime render them less liable to be attacked by vermin? The soil is light, but the situation damp and overgrown, and ground vermin are abundant. I plant the Gladioli in a prepared trench 3 feet wide, filled with made soil to a depth of 3 feet. This may possibly encourage wireworms. If you recommend lime, in what proportion ought it to be mixed in a trench of the above dimensions? I always put a handful of sand below and above the bulb.—PHILO GLADIOLUS.

[You were not worse off than nine-tenths of all the *Gladiolus*-growers last year. The year before was so wet that the bulbs never ripened properly, and we personally know that the thrips and red spider had an exhibition time of it all last summer. But our *Gladiolus* bulbs were planted in 1859, and there they are and shall be as long as we live, and no one shall disturb them the while, and, of course, we shall be better off than you and most of them next year; but your *Gladioli* will do pretty well if you can get rid of those grubs and the wireworm. Lime and soot would be good things to make the beds or trenches uneasy for them; the whole surface to be first made as black as soot can make it, and then to be made as white as snow with lime; and no more than a score of castocks would rid you of all the wireworm in one week, and this kind of castock must be the sappy stems of any one of the Cabbage tribe, cut into shreds and stuck into the soil and looked to every day to kill the vermin.]

VARNISHING WOODWORK OF A GREENHOUSE.

I AM building a span-roof greenhouse with pitch pine, and, on account of the beautiful grain of that wood would prefer dressing it with anything rather than paint. What would you recommend? Do you think boiled oil or varnish would answer, and if so, would it preserve the putty as well as the timber?—JOHN STEVENS.

[We would paint the putty, and when thoroughly dry, varnish that as well as the wood. Many stations of the railways, in Scotland especially, are so done and wear well.]

HOT-WATER HEATING—SOWING WELLINGTONIA GIGANTEA.

YOU were good enough nearly twelve months ago, to give me some useful information respecting the best form of boilers and pipes for heating a lateinery. I adopted your advice in many points, and have found the apparatus work well; but as I believe, in some respects, my plan is new, it may be useful to detail it, for the benefit of those who may yet have vineries to erect.

Further, I profited by the advice of one of the most skilful Vine-growers in the north of England, in forming the house itself, and Vine-border, and as I observe you have frequent inquiries on those points in your pages, I will with your leave begin at the beginning, and state very particularly in what way I proceeded.

Having fixed upon the site for theinery, which happened to be in an old pasture lying to the south of my kitchen garden, in the first place all the fine old turf necessary was pared off precisely as if it had been wanted to lay a lawn, and laid up in stacks, with a layer of old cowdung between two layers of turves. The frosts of winter had a pulverising effect upon the turves, and in spring when we were ready for the border, the whole mass was chopped up with spades, turned over and over, and thoroughly amalgamated.

Having then staked out the positions of the house, back shed, a-h-pit, &c., we ran a drain from the latter point due south under the intended border, and made another drain along the entire front of the border. A wall of stone lined with brick, and containing a flue, was then put up, in length about 50 feet, height 13 feet or 14 feet, and a shed 35 feet long, and divided into two parts for boiler-house, tools, potting, &c., was placed at

the back. The vinery is 35 feet long, and there are seven lights, each 5 feet wide. There is no wall in front, but eight pillars of brick 9 inches square support the wall-plate, upon which the front lights rest. Each light hangs by hinges at the top, and may be pushed out for ventilation; but my adviser warns me against giving air here. The rafters are 15 feet long, and the lower divisions of the lights, which are 11 feet, are fixed. The upper lights of 4 feet long slide by means of pulleys, ropes, and weights, which hang in the back elied; but I can ventilate at pleasure from the inside of the house by means of a pole very similar to a boat-hook.

The border is both inside and outside, and a two-foot wall about 3 feet from the front of the house supports the former, and also makes a convenient stand for plants. In making the border, about 2 feet depth of broken bricks, stones, and lime rubbish were first deposited as a foundation, and upon this the compost was laid to the depth of about 2½ feet, with a rapid slope to the south. Within the house, and immediately under the supply-cistern a deep reservoir is sunk; this is filled from the roof, with a waste-pipe into the drain beneath the border. I have a garden force-pump with a pipe reaching nearly to the bottom, fixed in the lid of the reservoir, and with this I can deluge the house when necessary, and can also fill the boiler from the supply-cistern.

My heating apparatus consists of a cylindrical wrought-iron boiler 3 feet long by 1 foot 6 inches wide, with four flues through the middle of it. It is set so that the fire plays over the top, passes through the flues, and then goes into the long flue which runs, in the back wall, to the other end of the vinery, and so up a chimney there. The pipes are 4 inches round, cast with evaporating-troughs on the top. There are two flow and one return, all lying side by side, which extend across the east end, along the front to the supply-cistern, and so back to the boiler. These pipes are rather more than a foot above the ground, and hence a difficulty respecting which I will afterwards ask your advice. Owing to various unforeseen delays we were not ready to plant the Vines, two to each light, &c. (principally Black Hamburgs and Frontignans), until the second week of June last. They were not thicker than straws, and were planted outside and brought under the wall-plate; but by keeping up a steaming atmosphere averaging 70°, the Vines sprang up to the top of the rafters and half way down the back wall, and in October the wood, nearly as thick as my little finger, was thoroughly ripened and in splendid condition. I attribute this result, in a great measure, to my having the power, by means of my forcing pump, to thoroughly deluge the inside of the house, at the same time keeping up the heat.

The difficulty to which I above alluded is this—I think of adding a conservatory to the vinery, and wish by the present heating apparatus to heat the former but not the latter. You will see, if you can follow my description, that I am debarred from making a door out of the west end by the pipes, which there cross the house, and if I place the conservatory at the west end, how can I heat it and leave the vinery cool?—A SUBSCRIBER.

P.S.—Is there any difficulty in raising *Wellingtonia gigantea* from seeds, and how long are they generally in germinating after being sown in spring?

[Your operations as to border-making, &c., are more generally successful than new. Had we such material, we would, perhaps, not have chopped it so much, and would like to have added some calcareous matter. We have always advocated that little is gained by planting Vines when the ground is cold. The only thing that surprises us, is, that after making a border inside communicating so freely with the outside, you have nevertheless planted the Vines outside. See notes on Rockfield, &c. The success, however, is very encouraging, only it may be as well not to use too much moisture in the house, nor yet to take much fruit this season.

We see no means of getting out of the difficulty, as to heating the conservatory, without a change near the boiler, which might have been provided for at first, if a conservatory was then thought about. We could manage the conservatory with little alteration, and heat it only when wanted, but that would not enable us to prevent the heat going to the vinery. The simplest mode would be to cut the flow-pipe as near the boiler as convenient, and there insert a knee-piece with a valve-joint, stopping the flow into the vinery, and branch flow behind leading into the conservatory, with a valve likewise on that, so that the flow to either house may be shut off or let on at pleasure. If the

boiler is low enough to permit the pipes being lowered at the pathway, it would also be desirable to have free access from one house to another, and on the same level. The pipes in the house might remain then just as they are, except the ends beyond the doorway would be fixed in an upright socket, and the junction of the pipes for both houses, and their respective valves, could be below the floor-level. You would find it a great advantage to have free communication with both houses. The same thing might be done without these valve-stoppers, by taking the flow-pipe from the boiler to a cistern close to the back wall a foot or two higher than the pipes—say 24 inches or 30 inches, and one pipe might go from that cistern below the pathway, to communicate with the raised pipes in the vinery, after passing the doorway, and another pipe would go from the cistern to the conservatory. The return in both houses may go to the bottom of the boiler by a joint or T-pipe there.

You need not disturb yourself by shutting off the returns unless you like. Provided there are the means of circulation, the returns will take care of themselves. The holes in the cistern may be regulated by plugs just as you like, and there is no danger of getting out of order, as the best valves in these socket-joints will do. We stated above, that if it had been merely to heat the conservatory, less trouble would have been required. A gentleman last year had a small conservatory just heated as your vinery is, he put up a glass case on the one end of it, and was anxious to keep out the frost merely to keep things alive in it; but he was frightened at the idea of a heating bill, and must have no alterations made, and, besides, had as many three-inch pipes by him as would do what he wanted. Well, we recommended his drilling a hole in the middle of the flow and return-pipe 1 inch, or, rather, 1½ inch in diameter, and in this was securely fixed 2 feet of a lead pipe with a brass tap fixed in the middle of it. The other end of the lead pipe went firmly with red lead into a piece of wood, that plugged-up the end of the three-inch pipes, these pipes being placed as flow and return in the usual manner. The gentleman believed that the turning of the brass tap would keep out the heated water, but he would not believe until forced to do so, that the turning of that beer-barrel tap would soon cause the pipe to be almost as hot as the pipes in the conservatory. The materials being on the place, there was little more expense than the taps, the pieces of lead, and the Portland cement for the joints. Altogether, the success was so much prized at the time, that there was no end of badinage, and for sanguine people there might have been a vision of a hamper at Christmas; but our own experience would lead us to the conclusion, that even the receipts at the office of the great *Punch* are matters that have their existence in a heated imagination, rather than in solid reality.

Keep the seeds of the *Wellingtonia* in a cold pit, and let them have their time. Fresh seeds will come up the quickest. If yours have been long kept they will require more time, and may not come up at all. If you suspect age keep them rather dry.]

SOWING MISTLETOE SEED.

In reference to the Mistletoe question. I inserted a number of seeds some five or six years ago, under the bark of different trees, making an incision, and after pushing in the seed, merely pressing the bark down upon it. If done beneath the branch I do not think the birds molest the seed, for, in fact, they do not find it. I cannot say my practice is very successful, as I have only two plants on a scarlet Thorn, and the growth is extremely slow. Indeed, one plant is not 3 inches long, the other about 6 inches.

Is it possible that *Viscum* being diocious, the seeds are not always properly fertilised, and hence the want of success, for nothing is simpler than the process of sowing? I have not succeeded by grafting.—A. R., *Bromley*.

DEATH OF DR. MACKAY.—With sincere regret, we have to announce the death of this generally and highly regarded man. It is true that it was not an unexpected event, for he had reached the great age of eighty-seven years, and paralysis for the last two or three of their number had weakened his sturdy constitution, which bronchitis finally subdued on the 25th of February. He died at his residence, Dawson Grove, Dublin. James Townsend Mackay, LL.D., is associated in the mind of every botanist with the "*Flora Hibernica*," of which he was the

author, and with the Dublin University Botanic Gardens, of which he was the founder, and had been the Curator for nearly fifty years.

CULTURE OF EUCHARIS AMAZONICA.

Last autumn I obtained a bulb of *Eucharis amazonica*, and I should be very obliged by any information about its culture. I received it in a small pot, from which I shifted it to a nine-inch pot, and have wintered it in a pit where the heat was kept from 55° to 60°. It has been not very damp at the roots, nor yet quite dry, but somehow it does not seem in a very flourishing state. It threw a sucker from its side, and that seems to take the lead from the parent plant. What more am I to do to this bulb, and when am I to expect it to flower?—G. R.

[Your bulb of the most beautiful *Eucharis amazonica*, is, just now, the most prosperous bulb in cultivation, and no one could have treated it better than you have done. It is an evergreen bulb, and, of course, you know evergreens do not always bloom in winter. All that you could now do to make this bulb worthy of being proud of, would be to have the pot plunged at the back inside of a Cucumber-pit, or a pit like it, where the air would be given overhead, and keep it there to the end of May; then out with it to the stove, and it will bloom as white as a Water Lily towards the end of July, or sooner or later; but any place affording bottom heat will do the spring work, and old bulbs do not require it. But keep your bulb in the same pot all this year, and the first half of next.]

TREATMENT OF OLD CAMELIAS, PEAR TREES, AND ORANGE TREES.

I HAVE lately come to this place, which is ninety miles north of Dublin, and have some large plants of Camellias; they are in tubs, but the blossoms are not larger than *Pompon Chrysanthemums*. I think that the soil is very poor, for they are growing in part loam and part peat, both of which I think are very poor. Now, I think of cutting the plants back, then starting them in a Peen-house that I have just begun to work, and after they have made a little growth getting the greater portion of this soil off them. Afterwards I would tub them in good loam and peat, with portions of bone dust and charcoal. Do you think that I shall have bloom on these plants next year? If so, I would prune rather hard to get them well furnished.

I have also a lot of old Pear trees with very old and long spurs; I am told that they bear no fruit. I purpose cutting off those spurs close to the branches, then rubbing off some of the shoots, and after breaking treating those that I retain as directed in *THE JOURNAL OF HORTICULTURE*, No. 41, page 294, fig. 5.

There are a great number of trees here covered with moss. Can I get it off with lime newly slaked? I have also some Orange trees that I think of serving like the Camellias.—Y. C.

[Your large Camellias are now in large tubs, and are unshapely and produce small flowers. To bring them into health you should, first of all, procure a quantity of fresh light turfy loam, and some sandy fibry peat or heath mould; and also some well-decayed leaf mould. Mix these well in the proportion of two parts of the loam, one part of the heath mould, and half a part of leaf mould. You may add about an eighth part of charcoal, broken in small pieces; incorporate thoroughly together, and place the mixture in a warm shed to become moderately dry, and have the chill taken out of it. As soon as that takes place repot your Camellias in it, taking care to drain them well: this is an important point, for if not thoroughly drained the young fleshy roots perish every winter. This repotting should be done immediately in order to obtain root-action before the plants begin to grow. The same practice is adopted by the best planters of all kinds of trees, the season of rest being preferred—that is, the autumn, to planting late in spring.

In potting pick out as much of the old poor soil as you can without injuring the roots. If the roots are very much decayed it may be advisable to repot the Camellias into smaller pots or tubs. On that point exercise your own judgment.

As soon as they are all put into this fresh soil, place them in a cool greenhouse for a month or six weeks till you observe the young shoots are pushing, then place them in a warmer house and use the syringing daily, but not too much water at the roots, only just enough to keep the soil moist; you may give more as

the season advances. With regard to pruning, you need not be afraid to use your knife. The best time is just before the growing season commences; the dormant buds are then ready to push forth, providing any roots above them are cut away. Continue a liberal supply of moisture in the air and at the roots through the growing season; but as soon as the blossoms begin to be formed cease syringing, and give less water at the roots. This is preparatory to removing the plants into the open air towards the end of June, or beginning of July; choosing a place in your garden where they can have the benefit of the morning sun till about ten o'clock, and after that time be shaded from it.

Your Orange trees may be treated in the same way as the Camellias, only they thrive better in a stronger loam, and can bear a stronger heat when growing, and also, unless you are in a warm, sheltered place, it is not advisable to place them out of doors even in summer. In the south of England they may be set out in the open air; but in the north the leaves turn a yellowish-green when fully exposed, giving the Orange trees a sickly, unhealthy appearance. In such a climate it is much better to keep them continually in the greenhouse or conservatory.

If your old Pear trees are healthy and growing strong, severe pruning will cause them to produce a great quantity of young, unfruitful branches: therefore, supposing them to be healthy, root-prune them immediately, and prune them as you describe you intend to do, then disbud part of the young shoots and nail some here and there to the wall. It is possible then you may have some few fruit-buds this autumn, and afterwards your trees will be fruitful. If they are weak and sickly, then cut off the long spurs, remove part of the old soil and replace it with some good loamy turf-sods, without any manure. This will throw fresh vigour into your trees, and restore them to a fruitful condition.]

PROPOSED BIRMINGHAM ROSE SHOW.

AN advertisement in our columns to-day announces a meeting for the purpose of establishing, what we cannot but anticipate will be the introduction of more than one annual horticultural show at Birmingham, and we are ready to believe that the same energy which established Bingley Hall and its exhibitions will be equally successful in this effort.

In addition to a Rose Show, it is proposed to include an exhibition of garden ornaments of every description, and of horticultural tools; the whole to be assembled in the noble Town Hall of Birmingham. The project is countenanced by all the principal local amateurs, amongst whom are included many gentlemen of influence.

No endeavours we are told will be spared to insure a first-class Show, and the promoters have no other objects in view than the advancement of the interests of horticulture, and the supplies to this town and neighbourhood of a fresh source of pure enjoyment. The Show is announced to be open to all England; but, we presume, Scotland is not to be excluded; for the promoters want to enlist the support of all the great growers; and one circumstance in favour of a show at Birmingham is that it will be especially appropriate for northern florists, who cannot bring their out-of-door flowers forward enough to compete with those of the southern florists. The days of exhibition at Birmingham ought to be later than at London.

A FEW DAYS IN IRELAND.—No. 15.

(Continued from page 413.)

ROCKFIELD, COUNTY MEATH.

THIS compact residence of Thomas Rothwell, Esq., is within a few minutes' walk of the station at Kells; and, from the level character of the ground in the neighbourhood, has to depend chiefly on its own park and woodlands for rich views and picturesque scenery. Much has already been done to enhance and give variety to the charms of the landscape, and much more will no doubt yet be accomplished by the liberal, enterprising, and improving proprietor. The neat lodge and handsome gates stand at right angles with the public road, a sweep inwards on each side giving an abundance of room. The approach, though not long is considerably varied, passing first through a grove or

wood, the road hard and smooth, the curves easy and graceful, and the verges of unequal width, from the trees and shrubs advancing and receding, and thus preventing monotony of outline. Anon it enters the park, showing the mansion on the right, past which it sweeps, and the site of the gardens, the offices on this side being concealed by planting. The park in front of the mansion is also considerably varied, the trees being somewhat regularly dotted on one side, and arranged in more selling separate picturesque groups on the other, backed by denser masses of timber. Through these woods and groves are many beautiful walks, and seats, and summer-houses, which must be pleasant in hot days in summer. In many places we noticed fine young undergrowths of Laurel, and have no doubt that in comparatively open spots Rhododendrons would thrive equally well. One advantage of the low position will be that water may be induced to lend greater attractions to the scene, as we have a vivid recollection of scrambling with difficulty over a rivulet to look at a huge heap of couple-t.

Not wishing to pass the entrance front of the mansion, and more especially when a carriage was standing there, we turned in at a gate on the right, hoping to get into the garden through the stable and farmyards; but all doors leading that way were fast and secure, so that we were forced to pass the mansion and a small flower garden at the side. We at length got to the kitchen garden and met with Mr. Watt, and experienced all the kindness we could expect from an old friend, though we had only once had the pleasure of meeting him before this visit.

The sight of the place rather bewildered us, and led us to conclude that in the building way there had been little done for years in the style of modern ideas, except what had reference to the mansion itself. The garden is so peculiar and so mingled, that we should be sorry to hear of its being ruthlessly modernised. Without a rough plan and sketches, we could not give an idea of the appearance of romantic antiquity that would be so charming to many. The chief impressions left on our mind are a wide slip for vegetables, &c., on the side farthest from the mansion, bounded on two sides by one of the finest hedges we ever saw, and on the other sides by massive stone walls 20 feet in height; other walls of the same dimensions reminding us of the outer and inner fortifications of an ancient keep, and conjuring up ideas of raids and forays instead of the more harmonising pursuits of gardening; then lesser walls and lesser divisions, where we meet with pits, frames, and all these essentials for modern gardening; and again, where we could scarcely expect it, a fine green lawn, with a miniature lake, soon to have its sides rendered romantic with rockwork, and its stillness broken by the trickling and dashing of a fountain; and on the lawn already many fine things, among which we noticed good plants of *Rhus Cotinus*; spirent bush Filbert trees; fine specimens of *Rhododendrons*, showing what such plants will do in such a climate; and among good Hollies, one white variegated one 19 feet in height, and 36 feet in diameter of head where it swept the ground.

As in other places, the supply of fruit this last autumn was below the average, and some of the trees on the walls may have done their duty in days that are gone; but we believe that ere long, what with planting, and grafting, and lifting, and pruning, these gardens and walls will be stored with all the best fruits that will ripen in the climate. Other departments will follow in the same race of improvements. From what we saw we have every reason to believe that, owing to the good taste, the experience, and the intelligence of all concerned, all these modern improvements will be gradually introduced into this singular old garden; and, yet, with such a conservatism and care-taking of the marks of the old and hoary as not to disturb even the prejudices, and far less the well-founded veneration, of an old buck of an antiquary.

As a first-fruit and earnest of future improvements, we noticed a massive range of glass houses, recently erected, more than 100 feet in length by 14 feet in width, and from 5 feet to 6 feet in height at the front, and 14 feet to 15 feet at the back, divided into three divisions—a Peach-house and two vineries. This range is to be extended about 60 feet, to be divided into a plant-stove and greenhouse. And now, we understand, there is building a span-house 80 feet by 12 feet for Melons, Cucumbers, and early vegetables and flowers. In building these any slight errors overlooked in building the first range will be more easily avoided. We would not have alluded to any small desirable improvements in the new range which we saw had not Mr. Watt solicited our candid opinion; and, as we do not even

know the name of the builder, and could find no fault with general details, the mention of some minor matters, which we deemed would be improvements, may be of general use and advantage.

The first thing that struck us there with respect to this range, as well as some other new ranges in Ireland, was simply this—that there was not half enough of top ventilation. The front ventilation is ample enough, the whole of the front sashes swinging on pivots, being shut or opened less or more by means of an iron rod and lever. The broad roof is almost like a sea of glass, fixed, stout rafter sash-bars, and the squares of glass being 20 inches by 39 inches. A ventilator about a foot deep is placed in the back wall at the apex, opposite every third square of the roof; but that in a hot summer, without the bother of shading and thus counteracting the clear light from the roof, would not prevent scorching and burning, and plenty of red spider to the bargain. From the mode adopted the opening even is not so large as it seems. With such a mode an opening at every alternate square would hardly be enough; it would have been better to have had the whole back thus ventilated, with the exception of the necessary small piers to keep up the higher part of the wall. Provided that a sufficiency of outlet for heated air can thus be given, the plan has much to recommend it, and especially in early forcing. The roof being all fixed, before much air is needed, it will be mellowed and heated by reflection from the glass before it rushes in at the opening in front of the wall and gets down into the atmosphere of the house, thus avoiding the ruinous effects of cold draughts. Air can thus be given plentifully, even in wet rough weather, when it would not be desirable to move sashes, or even top ventilators. The very advantages of the system, however, demand plenty of power at command, as the air in general admitted will be warmer than it would be if admitted from the north side of the wall, or even at the apex of the roof where there is no projecting wall to reflect the sun's rays. In the case of a single house much relief could be obtained by opening the spaces above the doorway, where, in a hot day, we would expect the air to rush out with a force sufficient to drive a windmill; but in several divisions that cannot be depended on. To make all sure Mr. Watt tells us he is now introducing Moore's Patent Ventilator, the size of the square of glass, between every alternate two squares at the apex.

The second thing we noticed was that the floor was pebbled inside, and had neither stages nor pit inside, so common in vineries in Ireland. We believe that a flagged or pebbled floor is a fine thing for reflecting light and heat, especially in the case of late Grapes; but Mr. Watt will be lucky if he be able to keep the floor from being otherwise occupied. We also noticed that a paved pathway went close to the back wall, opposite the doorway at each end. This is very convenient, and in the case of established vineries brings the best bunches most prominent above the eye; but for houses to be made the most of, it would be better to have the door in such lofty houses, and the main pathway some 15 inches or more from the wall. A crop might then be obtained from the wall before the front trees monopolised the roof; and if that were not desired, a series of shelves for Strawberries, Beans, &c., could be better seen and attended to.

The only other particular thing which we discussed together was the mode intended for planting the Vines. The front wall was built solid, and small holes left for the Vines to come through. Owing to circumstances, which we could not alter without having everything changed, this is the plan we had to follow ourselves; but we by no means approve of it. In all cases, but especially of early-forcing vineries, it is important to have the stems inside of the house. The great things to be attended to in that case are to have the arches of the front wall high enough, so that the roots go out freely, and not to have the outside border higher than the inside one. The difficulty in this respect at Rockfield was the nearness of the stack of heating-pipes to the front wall. That, however, has since been overcome, by a little alteration we presume; and now, after building a four-inch wall in front of the pipes, and breaking arches in the previously solid wall, there is a space of a foot wide for planting the Vines inside, each Vine in the centre of the arch-opening.

The mode of forming the border is, perhaps, an improvement on that of Mr. Scott, of the Vice-Secretary's, Phoenix Park, as detailed in these pages, No. 5; Mr. Watt, considering the moist climate of Ireland, is no advocate for deep borders. The sub-soil is gravel, and above the drains the depth is 32 inches—12 inches of rubble and 20 inches of soil. A drain 12 inches square, and covered with flagstone, goes along the front. Two

other drains pass longitudinally along the border—one along the middle, the other close to the front wall of the house. These are all connected with cross-drains, 4 feet apart, of earthenware pipes 4 inches in diameter. At the junction of these, close to the wall of the house at every other archway, they communicate with the surface of the border by perpendicular pipes. From each of these perpendicular pipes a horizontal pipe passes inwards through the four-inch brick wall previously alluded to, and in this is fixed a circular ventilator, so as thus to admit rarefied front air when it might not be safe to open the front lights. The main deep drain is furnished with four uprights, or shafts, and these being much lower than those at the front wall of the house, a constant circulation through the border will be secured, and air admitted into the house at pleasure, rarefied by passing through the border, and more rarefied and heated by passing among the stack of pipes. The top of the air-pipes outside will be fitted with wire gauze, to keep out vermin; and in very severe weather, they can be kept open or shut at pleasure." See sections.

Section of Viney.

Section of Peach-house

End elevation.

We will just notice two more things—first, several nice plants of Figs, raised from seed from dried Figs sown by the young ladies some eight years ago, which have never yet fruited, but which we feel sure will soon do so under such glass houses as now may be at their disposal, with a little curbing of the roots, and nipping the shoots. We trust that the fruit will be worth waiting for, though in such a case it will be pretty well a lottery as to desirable qualities. The second things were several white-leaved plants somewhat like *Cineraria maritima*, but altogether distinct in habit, as having a decided trailing tendency; the main shoots being bristled all over with short, stubby, white-leaved shoots, and, therefore, would look splendid suspended from a basket. Mr. Watt informs us that some plants have shoots now

6 feet long, and thinks, as it is half-hardy, it would make a fine low edging plant pegged or laid down. The parent plant was obtained from seed three years ago, sent from the Cape of Good Hope under the name of *Arctotis grandiflora*, and the plants at Rockfield were raised from that, as every inch of the plant will grow. We rather think, however, that this trailing or hanging feature is a peculiarity, as, from what we recollect, the *Arctotis* referred to was rather upright in habit, but we may be mistaken. Such a plant of good size would form a fine feature suspended from a basket in a large conservatory. Though no doubt easily propagated, and though generally successful, we have been particularly unfortunate with this very desirable thing. Mr. Watt gave us a few cuttings, which were ruined by coming within the clearing sweep of the chambermaid at Dublin, and then,

on getting a few sent by post, they were so smashed by stamping, that we were beat in trying to get them to live. If the plant is at all common we have not seen it before; but for edgings to small beds and for hanging from a basket, we feel sure it will be an acquisition. We hope Mr. Watt will try it for different purposes this season, and report progress. R FISU.

PLANTS FOR SUSPENDED BASKETS— CAMELLIA-BUDS BROWN.

I WANT from the end of May to the middle or end of August, to have four suspended wire baskets in my conservatory, filled with some plant or plants that will be very gay and ornamental during that period. What would you recommend? I have a large *Camellia* with which I am sadly afraid there has something gone wrong. The buds have come forward to a certain stage and suddenly stopped, and are commencing to turn brown. It has been suggested to me that it was put out of doors in an exposed place too early last spring. Would such treatment cause this? —A SUBSCRIBER.

[For suspended baskets to hang—say from 3 feet to 6 feet below the basket, we question if you could have anything better than white, crimson, purple, and pink *Maurandias*—say three nice plants of a colour to each basket, if from 12 inches to 15 inches and 18 inches in diameter, and three stout plants of *Lobelia gracilis* between the *Maurandias*. If the house was kept warm and moist, we would then think of *Thunbergias* and the best *Convolvulus*. The baskets may have a stubby centre—such as four varieties of *Fuchsias*. Your *Camellia* is more likely suffering from want of water, or too much with deficient drainage. You may plant your chubbers now, but do not over-water until they are getting into fresh soil.]

EDGING PLANTS.

How close should cuttings of Variegated Balm, about 3 inches or 4 inches high, made last autumn, be planted to insure a good effect for edging this season? Also would cuttings taken this spring do as well? Will *Cerastium* that has been out all winter and turned green recover its colour? Does Purple Orach do well for ribbons or panelling, and would it agree with *Perilla*? —ISQUIBEL.

[The distances at which any cuttings or plants from last

autumn's cuttings should be planted apart depends on three things—the first of which is the size of the plants; the second the kinds of plants which stand behind, or before, or on either side of them; and the third is the eye and patience of the owner. A good eye likes things to be as they should be, and it is an eyesore to see anything as it should not be; but good patience allows good distances between bedding and ribbon plants to give the plants the proper room and strength to blossom well. Well, but Variegated Mint (we have no Variegated Balm for bedding sides), does not bloom, or is not planted for bloom, and one can go on the principle of cutting according to the cloth, and plant the Mint at 1 inch apart, or 2 inches, or 3, 4, 5, or 6 inches—the widest distance that can be allowed. 1 inch apart is not too thick planting, no matter how big the plants are; 3 inches apart are not too wide, no matter how small the plants may be.

Cuttings of Variegated Mint made at the latter end of April, if planted in double rows 3 inches apart, and 2 inches plant from plant in the row, would make extremely pretty lines like those that Mr. Eyles gave us last season in the new garden at South Kensington.

Purple Orach requires a good eye, a good hand, and a good judgment to make a splendid row of it; the contrary would only make an eyesore of it. It and Perilla would agree in making two shades of purple; but purple flowers or leaves are not very good subjects for shading or for night light.]

ABIES ALCOQUIANA.—*J. G. Veitch.*

MR. ALCOCK'S SPRUCE FIR.

AMONG the Conifers that have been sent home by Mr. John G. Veitch, is one which he has named in honour of Mr. Rutherford Alcock, Her Majesty's Minister at the Court of Yeddo, and of which we furnish our readers with an engraving drawn by Mr. Fitch. It is said to be "a noble Spruce Fir, in some respects resembling the *Abies potida* of Zuccarini, from which it differs in having much smaller cones, with scales of a different form, very small leaves, glaucous on the under side, blunt or emarginate, not mucronate, and flat, not four-sided.

Mr. Veitch found this on Mount Fusi-Yama, at an altitude of 6000 to 7000 feet. The tree is 100 feet to 120 feet high, and the wood is used for light house work.

SHADING GREENHOUSES.

THE aspect of my greenhouses being almost due south, sun-blinds will be required in the summer, and the wire trellis prevents my having it inside. I propose placing them on the outside, on a roller to be drawn up from the back, such as I saw in 1860, at Kew Gardens, but do not recollect the kind of cloth used. Would you recommend "frigi domo," "Brown's floral shading," or what other texture? Would mulling the glass with putty, putty, or whitewash answer the purpose? and if so, should it be put on outside or inside?—S. D. GORF.

[Frigi domo, or what you prefer, will answer for an outside blind. The modes of managing them have been frequently given.

For shading, the following composition is good:—One quart of jelly size, one quartern of soft water, half a quartern of turpentine, half a quartern of luscoid oil, the size of an ordinary walnut of whitening powdered small, and all mixed together and heated until near the boiling-point, then laid on whilst hot as thinly as possible with a brush, and the place dotted with the points of a dry brush to give it a ground-glass appearance. This will keep on for the season, until heavy autumn rains, and a brush with warm water will remove it when desirable.

We do not see, however, what you want a shade for a house in which Vines are grown. We would prefer more air and all the sunlight possible. Melons and everything else that are grown for fruit are better without shade; but, like rickety children, if you commence with it you must keep on. A little temporary shade is often wanted when bright sun comes after a course of dull weather.

OIL FOR A WALTONIAN LAMP—NEMOPHILA SOWING.

CAN you inform me what sort of oil should be used for the lamp of a Waltonian Case? I have tried two kinds, and both produce too much smoke and smell to admit of the Case being kept in a sitting-room. Can the flue need cleansing. If so, how is it to be done?

Can *Nemophila insignis* by repeated sowings be depended upon for making a good blue bed until October. If so, how often should it be sown?—AN OLD QUEERIST.

[*Nemophila*, blue, white, and variegated, can be had in bloom every day from the first opening in April till the middle of November, if the frost would let it go on, and people choose to take the trouble to do it so. To have it thus, however, you would need to devote five beds, if not six to it, instead of one, and five or six sowings. The first at the beginning of September to bloom in April—say to be in bloom by the middle of the month; the second bed to be sown at the end of February; the third at the end of March; the fourth on the 10th of May; and in most seasons, the fifth sowing would do any day of the last week in June; but to make quite certain we would have a sowing the last week in May. We once used to have one row of the blue *Nemophila* 75 yards long in bloom every October Newmarket day, and in most seasons it lasted out through November, and in snow it was a beauty.

Mr. Walton himself uses the best colza oil at 5s. per gallon, from Bond Street, London, and his Case is now the only one that we can have a look at. There is no soot, or any flue or chimney-sweeping about it. But there is a nicey about trimming all kinds of oil lamps which some people can never hit on, while others never meet with the smallest difficulty in doing them to the shade of a flame. The very same lamp and Case which Mr. Walton had seven years since are now at work, and look just as good as the first season. The gardener likes it, and looks after the lamp of course; but in the spring, we believe, Mr. and Mrs. Walton do most of the cuttings and sowings if all were known.—D. B.]

VENTILATING A LEAN-TO ORCHARD-HOUSE.

I HAVE an orchard-house 22 feet long by 12 feet wide. Sashes in front about 20 inches deep, which open the whole length of the house. Two apertures, one at each end, at the point of the roof, about 10 inches by 9 inches. The ends are brick about 3 feet high, above which they are boarded. It is erected against the wall of a house, so that there are no ventilating-shutters at the back. Please tell me in your next Number if this will be

sufficient ventilation. Also, please say, if Peach trees, &c., will do well, the tops of the trees being about a foot from the glass.—A. B.

[You will search the trees against the back wall. If the openings at the end were 1 yard square instead of some 10 inches, and you had two more in the middle of the roof, at the apex, you would do. At present we know you will fail if your house is a lean-to. If it were span and air on each side, it would be different. The Peach trees will do as well if 15 inches or 18 inches from the glass.]

COCOA-NUT FIBRE REFUSE.

I APPLIED in accordance with your recommendation to Jackson, of Sydenham, to obtain some cocoa-nut refuse for growing Ferns, but found that he had parted with all his stock. Could you inform me in your next Number where it may now be had?—A. CONSTANT READER.

[The Cocoa-nut is crushed for the fibre only, and that only at Kingston-on-Thames. You must not only send your own cartman for it, but he must fill his load himself, and he can put into his cart just as much of it as he likes, so that one horse can carry it, and for that 2s. only are charged. That one load would do for twelve months, grow all the Ferns in ten of the largest private Fern establishments in England, Ireland, and Scotland. Two shillings worth of it would do more good to most of the Ferns in the ten collections, than twenty loads of the best peat and two loads of Reigate sand, for this stuff supercedes all sand and peat for Ferns. Then if twenty of the large, fifteen of the larger, and ten of the largest growers of Ferns were each set separately, to club so many pence or shillings, and send one cartman for a load to be had in common, or divided by the bushel, or to be sent from London by rail, they might have it nearly as cheap as we in Surbiton.—D. B.]

CULTURE OF HERBACEOUS PERENNIALS.

(Continued from page 436.)

TYING-UP, STAKING, AND THINNING THE SHOOTS.—In order to keep the plants tidy and neat in appearance it will be necessary to provide a sufficient number of sticks for the whole. The making of these is a nice winter's job for the gardener or amateur. For the tall-growing species, of course, long sticks or stakes will be necessary. I know no stakes so good as young larches—such as are easily obtained where large quantities of that useful timber are grown. For less sizes, split red deal, I believe, makes the best sticks. The larch stakes will last longer if the part that is thrust into the ground is carbonised—that is, just partially burnt in a fire, and the bark left on the remaining part. The other kind of stick should be painted three times over with dark green, and well dried previous to using. Before commencing to place the stakes and sticks to the plants, let the operator examine the plants, and where there are a considerable number of shoots, thin them out judiciously by cutting part of them down close to the ground, or, where they will bear it, even by pulling such extra shoots clean up. The object in thinning is to obtain finer and larger heads of flower; and the sooner after the shoots spring up this thinning is done the less they will injure those that are left. If a bundle of shoots is allowed to grow up together they will be weak, leafless towards the bottom, and the flowers will be poor and insignificant; hence the necessity and advantage of the thinning process, which I fear is but seldom done or thought necessary to be done. Then place the stakes or sticks to the plants in good time, so that the shoots that are left may be early secured and protected from strong winds. I sometimes found it necessary to use more than one stake to a plant on account of the large number of shoots; but this is seldom the case—especially if the shoots are well thinned. Place the stake so that the shoots may be tied to it in a circle, without crowding or having a bundled appearance, and this tying-up must be continued till the blooms appear. The attention to this point is of more consequence than may be imagined. Tying-up a plant in a careless slovenly way not only injures its appearance, but frequently destroys at least a part of the bloom. Like all other operations in gardening it must be done at the right time or times, and done, too, in a neat manner without bruising the stems or leaves. The best material to tie with is bast mat. It should be cut into proper lengths, and fastened to

the waist of the operator. If he wears that useful article a gardener's apron, the matting can be drawn through the strings, and the apron tied-up also to hold any shoots that it may be necessary to cut off, and also the ends of the mat or any stray weeds that may be found growing at the time. All this may appear tedious and unnecessary for me to write and some to read, but I write for those who wish to learn and understand how to do everything they have to do in a garden in the proper and best manner.

WATERING.—Herbaceous perennials generally have abundance of fibrous roots, which are in fact the mouths of the plant, to draw in its nutriment. In dry weather the soil will be dry also; consequently these mouths will not be able to gather in any food, and the plant will suffer severely. Remember, the food of plants must be in a liquid state: therefore in dry seasons, if you wish your plants to thrive, you must supply them with moisture; and this is more necessary if the soil on which they are growing is of a sandy character and not very deep in staple. Loamy deep soils do not dry so quickly; but even such soils will dry on or near the surface, and the fibres in such parts will shrivel-up and the plants suffer also: therefore, understanding this, let the plants have a good soaking of water in such weather; apply it liberally, and in order that it may not evaporate too soon, apply it in the cool of the evening. A large watering-pot, with a coarse rose, is as good a utensil for the purpose as any; or what is better, a good large water-barrel on wheels with a piece of gutta-percha tubing, with a rose at one end and the other fixed near the bottom of the barrel, will water a long border more quickly, effectually, and easily than the watering-can. If the plants are not in flower, a gentle syringing will be of great service. This watering, to do any good, must be thoroughly done; mere dribbles do more harm than good. It is like giving a thirsty man a thimbleful of water when a whole pint would scarcely moisten his throat.

To prevent evaporation taking place too quickly, as soon as the surface of the border is just dry enough, rake it over and keep that surface loose; or if dry weather continue the ground will crack or open here and there in fissures, out of which the moisture will fly off into the heated dry atmosphere with tenfold rapidity. Many growers of florists' flowers, such for instance as the Dahlia and the Hollyhock, in order to prevent evaporation, spread over the ground a covering of littersy manure, which is of the greatest service—especially if water is given freely also; but this herbaceous plant-border being in a part of the garden that is highly kept, the littersy manure would not be sufficiently dry. I have used spent bark for the purpose, and where Fine Apples are grown there is generally plenty of that material which could be applied to cover the herbaceous border with good effect.

The above points being attended to properly and perseveringly, the owner may expect his border to make a goodly display of flowers through the season.

T. APPLEY.

(To be continued.)

WORK FOR THE WEEK.

KITCHEN GARDEN.

We are now arrived at the busiest month of the year, and to most gardeners one on the right use of which will greatly depend their success in keeping up a plentiful supply of vegetables for the summer's and winter's consumption. This can best be done by having the soil well drained, and ameliorated by the winter's frost and by a judicious rotation of cropping. *Asparagus*, permanent beds should now be planted and the old ones filled up, two-year-old roots are to be preferred. Give air freely to the plants in frames and make other beds for succession. *Beans*, if the weather will permit plant out these in pots or boxes. Earth them up after planting. Get in another sowing of *Windor* or *Longpod*. *Cavilflowers*, where there are more than four or five under each lanc-glass, they should be thinned out to that number and planted on a rich piece of ground; or, if the *Celery*-trenches are opened and manured, they may be planted in them, as they will be ready to come off before the trenches will be required for the *Celery*. *Dwarf Kidney Beans*, if there are any in the vinery or Peach-house keep them frequently syringed, to prevent, if possible, the appearance of the red spider; if already attacked the better plan will be to remove them to a pit or frame, where no injury can be done to other plants. *Herbs*, they should now be sown or propagated by division of the roots. *Pears*, plant out those in pots or boxes on

a south border; plant them thinly in the rows, if it should even be necessary to shake the whole of the soil from their roots. If the soil of the border is stiff or wet, lay a little leaf mould over the roots. Successional crops should now be got in; it is generally necessary to sow two or more crops at one time unless the quick-bearing kinds only are used. *Potatoes*, in planting the early crop it is of great advantage to draw deep drills, partially fill them with leaf mould, then plant the *Potatoes* and fill up with the same. *Sea-kale*, whenever the produce is cut from a root, and it is not likely that there will be more shoots from it fit for use, clear away the litter, and cut the long straggling shoots nearly down to the ground: this will keep them within the compass of a pot or box.

FLOWER GARDEN.

Complete any planting which circumstances compel you to do; but, otherwise, do not choose this season. Remember there is no time like autumn; plants then suffer but little from perspiration, and you get from the warmth of the ground an immediate root-action at that time. Sweep and roll the lawns well. Owing to the mildness of the weather our gardens are not likely to be disfigured this year.

FRUIT GARDEN.

Finish the nailing of all well trees. It is an erroneous practice still persisted in by some to cut out annually a large quantity of wood from young and luxuriantly-growing Peach and other fruit trees, instead of curtailing their roots; while, on the contrary, they leave sufficient wood in an old and weakly tree to suffice for two or three. The former practice produces disease and death, the latter small and almost worthless fruit. We do not recommend severe winter pruning of old trees, but that a much less quantity of young wood should be laid on in the spring; the fruit would then be superior both in size and flavour. As regards luxuriantly-growing trees, lay in all the bearing wood it is possible to do, and cut their roots in the autumn; or, what is better, lift them. Tie down the branches, before the buds swell too much, of the Pear trees trained *en quenouille*. Protect blossoms, much newly-planted trees, and water if the spring is likely to be dry. Prune and nail Figs. See that clay is prepared in good time for grafting purposes.

STOVE.

The plants of *Aphelandra*, *Clerodendron*, *Euphorbia*, &c., that have been cut down and are now breaking, should be shaken out and repotted in good turfy fibrous loam, with a mixture of coarse sand and a good portion of charcoal, in which these plants delight. Continue to increase the heat and humidity for the *Orchids*, and see that plants of *Dendrobiums*, *Gongoras*, *Stanhopes*, and some others that are now making their season's growth, are not suffering for want of water. It is sometimes found of advantage to soak them in a tub of warm water. Syringe carefully about the blocks and baskets that have plants of *Vandas*, *Saccolabiums*, *Sarcantuses*, &c., growing in them. Prick off carefully into small pots the various kinds of *Achimenes* as they make their appearance in the store-pots or pans, and put in another batch of *Gloxinias*, to be treated in a similar manner. They delight in moderate bottom heat at this season.

GREENHOUSE AND CONSERVATORY.

If cold easterly or north-easterly winds continue to prevail great care is necessary in the admission of air, as there is great difference between these harsh cuttings winds and the soft, quiet, gloomy weather that we have lately experienced. The different kinds of *New Holland* and other plants—viz., *Acacia*, *Eutaxia*, *Virellia*, *Templetonia*, *Brunghansia*, *Nerium*, *Laurus Camphora*, the varieties of *Cactus*, and others that have been at rest in the greenhouse for some time should be carefully looked over to see if the drainage is correct and the surface soil in proper condition, and that no plant becomes unsightly for want of water; pruning back or stopping with the finger and thumb. Previous directions to be followed up in the conservatory, placing every plant to the best advantage and clear from its neighbours; keeping well in view the judicious arrangement of colours. The creepers to be kept pruned and nicely trained, with the pathways matted dry early in the morning, that no complaints of unpleasant dampness to the feet may arise.

FORCING-PIT.

Introduce fresh plants for succession as fast as others are removed to the conservatory. Pinks which have trussed-up will be better in a milder heat, and Lily of the Valley should be removed to a lower temperature as soon as the first flowers are open.

W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

TRENCHER, turned over trenches, laid Box in five days, turned out the bottom of Celery-beds in trenching, so as to scatter the dung equally from the bottom of the trench, making the ridges in such case across the ground. Planted a few more *Cabbages* from the autumn sowing in succession, to succeed those which were planted out in the autumn. Transplanted some *Onions* that were sown in the middle of September, to get forward early large bulbs for use. Sowed a few *Radishes*, planted a few *Potatoes* as the ground was dry, and prepared by digging and turning for getting the soil into order for general crops of *Onions*, *Carrots*, &c. Potted *Cucumbers* into good-sized pots to keep them as yet in little room, and filled another box with *Asparagus*-roots, the first now showing signs of distress. Placed more *Rhubarb* in the Mushroom-house. Swept over the beds with a hair-broom, and spawned another small bed, wrapping each piece of spawn in a handful of dry short litter as the manure was wet enough.

FRUIT GARDEN.

Forked over slightly among rows of *Strawberries*, just to break and a little more the rough lumps of dung and leaf mould. Will give no dressing to the rows in the shape of removing old leaves, &c., until gentle April comes at season, and frequently give no such dressing whatever, as when the plants begin to come vigorously the fresh growth soon covers all the old, and there is no chance of fine strong buds being broken off by a careless hand, or a more mischievous rake—a tool by-the-by, which unless for specific purposes, should generally be under lock and key. Pruned, fastened, and painted *Apricots*, *Peaches*, &c., as opportunity offered. Did the same with *Currants*, *Gooseberries*, and *Pears*, and will finish with *Apples*. We have given over pruning *Gooseberries* early, on account of birds devouring the buds. Last year they made havoc even with *Apple*-buds, and this season they have commenced with *Pear*-buds. Daubing them over with a paint of soot, lime, clay, and cowdung in about equal proportions, and soapsuds as the water. It is so far a preservative that the delicacy of the morsel is for a time destroyed.

No one likes *birds* better than I do, and though we shoot at times, I neither care for the job nor for the noise the discharge makes in a garden. We have used, however, what is not much better—several windmills that kept up almost a constant clatter, and which kept the feathered gentry away until they got used to them. What with high game keeping in cultivated and woolly districts, where a boy runs the chance of being locked-up if he should peep into a hedge for a sparrow's nest, there is a growing danger that the birds will have more than their own share of garden produce, and it is more vexing to see them clearing a tree of buds than taking their own fair share of the fruit when it comes. The pretty tomit is about the greatest rascal, though not bad to poison when it is put into pieces of suet; but, then, cats too may eat it. If things go on in the same way much longer, we shall be compelled to cultivate our hardy fruit on low bushes or pyramids, so that by net and otherwise we may protect buds as well as fruit, and let the birds have only their right share.

Examined *Strawberries* in houses, cleaned them of all decayed leaves, saw there were no wormcasts in the pots, and top-dressed the surface with rich compost. Extra damp is ruinous in this dull weather and encourages attacks of green fly, which soon destroy the buds when pushing, and injures the fruit when ripening, and the flowers when setting. When the truss is throwing-up and a few appear, then there is nothing like the "Weaver" plan, "Catching and killing them"—in other words, bring the fingers and thumb in contact with them, and the slightest touch will destroy them; and then lay the pots down, and as they are turned over syringe them well with soot and lime water, rendered clear by standing long enough. When farther advanced a little may still be done with the fingers; but the great resource is tobacco smoke, presented cool and not too strong at a time. Tobacco, however, is no joke when much is wanted, and hence the importance of these preliminaries, and if not attended to until the plants are a living mass of insects, it is best to save the tobacco and throw away the plants at once. Potted *pyramidal Cherry* trees that have a fair supply of fruit-buds on them, and which had been sent in a bundle without any earth, the roots merely being wrapped in damp litter. The soil used, therefore, was rather dry, in order to get it in nicely among the roots, and these were placed so as to fill the pot pretty

regularly, and the soil squeezed tight about them with the fingers and a blunt piece of wood. The trees were then painted, to smother-up all insects' eggs, and the pots plunged out of doors into a heap of leaves, so that encouragement may be given to start the roots at once, whilst the buds will be kept back by open exposure, or even shaded from the sun if necessary, the intention being, if possible, to take these plants ultimately under glass, and get fruit from them before it can be obtained in the open air. By such a process we have had Vines in pots, well supplied with fresh sponges, before a bud began to swell; and even now there is a pot in a heap of leaves with part of a pruned-off stem in it, and a few buds exposed, showing in the open air no signs of moving, whilst roots 6 inches long and as white as milk are formed in the pot. So much for the root-and-leaf theory, showing that though for continual health there must be reciprocal action, yet to a certain extent, and for a definite purpose, the roots and buds can be separately excited into action. In the case of all fruiting trees in pots, we advocate fruiting them in these pots, in which the ball is full of roots, without shifting or repotting before the fruit is obtained; and to this there may be exceptions at times—such, for instance, as when the pot is very small for the head. In this case we would gently disengage the roots outside of the ball, place in the larger pot, and having secured the roots make the soil as firm as possible; and if it can be done, as in the case of a Peach, that a mild heat out of doors can be presented to the roots, so as to encourage rooting in the fresh soil, before the buds swell and expand, there will be little risk of the buds dropping from the change. Again, when trees with fruit-buds are obtained without balls, and it is desired to get them to fruit under glass, the extra heat at the roots, whilst the tops are cool, will be an advantage; because by the time the buds break, there will at once be a reciprocal action. With such exceptions, most fruiting plants in pots, from a Strawberry to a Vine, will do best in the pots that were full of roots the preceding autumn.

Turfed in fine days, swept and rolled walks, lawns, and attended to flowers; propagating and cold pits such as last week.—R. F.

TO CORRESPONDENTS.

* * We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the "Journal of Horticulture, &c."* 182, Fleet Street, London, E.C.

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

We cannot reply privately to any communication unless under very special circumstances.

GAY BORDER-PLANTS (An Experienced Amateur).—The best three bedding Scarlet Geraniums are Punch, Crystal Palace Scarlet, and Tom Thumb. The best three Variegated Geraniums are Alma, Bijou, and probably Flower of the Day, all things coming best three Calceolarias are aurea, floribunda; *integroloba grandifolia*, are one mainly used at the Crystal Palace, and Gaines' Improved Scolding of the same. The best three Verbenas are Robinson's Scarlet DeLancey, Purple King, and Mrs. H. Ford, white. One thousand plants of each of these three Verbenas are planted out in beds all over the three Kingdoms, for every one that is planted out of any other kind of Verbena, and it is from that fact that our selection is made, but if ourselves we have no particular choice or favourite in any of these classes, we merely echo the judgments expressed in the public gardens round London. But Mr. Gaines' Calceolaria being a new one to most people, we refer to our report of it last autumn from the Crystal Palace, where it made, most certainly, by far the best bed of Calceolarias we have ever looked upon.

FLOWER-GARDEN PLAN (H. C.).—Nos. 1, 2, and 3 good; 7 must be exactly the same as 2, being the match to it; 5 good also, but 4 not good, as Gazania looks better there without an edging. White border 2, 4, 7, 14, and 17 very good. The rest seem quite correct, and 8, 9, particularly good, though seldom seen. The row of circles under the "span-noted" bank is far more artistic than a border would be there; a ribbon-border there would be simply ridiculous, and a mixed border something more. You must have had excessive labour and thought to lay out such a situation so well.

CULTURE OF JACOBÆA LILY (A Working Man).—The Jacobæa Lily is *Speckelia tomosinifolia*. It is grown the year round exactly like Regent Potatoes in some places, and it answers the best of any way; but there are many ways of treating it, and by one of the ways it can be had in bloom from January to the middle of May, but by sowing it with the late Potatoes in the autumn, by keeping it dry and from frost like them, and by planting it

out full 4 inches deep at, and after the middle of April, it blooms naturally about the middle of May. The same treatment for forced Hyacinths will give the spring succession, and by keeping it always in pots the green-house bloom is generally over before April is out. It is more easy to do than any of the late kinds of Potatoes. We can form no idea of what your scarlet Cal Lily, or marjollyn can be; there are scores of bulbs would answer your description.

GAS STOVE IN A VINERY (D. P. Bell).—A gas stove may be used in any fruit or plant-house without any injury to their occupants, if a tube is so fitted to the stove as to convey away into the exterior air all the gases formed by burning the coal-gas. We used one for some years in a small vinery, without an injury to the vines or other persons occupying the house. The stove was at one end of the vinery, and the tube, or chimney, rose perpendicularly from the top of the stove, and when near the roof turned at a right angle, passed along the whole length of the vinery, and communicated with the open air through the end of the house.

PEACHES AND NECTARINES IN GREENHOUSES (Dorset).—Peach and Nectarines will do very well on the back wall of a greenhouse, provided you do not shade the trees with plants, and you do not keep the house above 40° in winter. If you had bearing trees there you might ripen that crop in a way, but if you also grew Melons on the roof of the house in summer, we would not give much for your Peach trees the year following. Wash and soak your Melon stems in a pair consisting of sulphur and sulphuric acid when you give fire heat place sulphur on the heating medium, provided that is not hotter than 150°; where it touches the sulphur 120° would be better.

QUEEN ANNE'S POKERY MELON (Idem).—The Pocket Melon is more pretty than any, hence, some people like it, and it looks nice on the table four or five in a dish. The thickening of the rind, and the softness of the pulp, depends more on practical skill and the season than on mere formal directions. Most Melons would have so ripened last summer in Dorset, we presume; but it was a summer amongst summers, at least with us a little north of London, in many parts the dull weather, and the late rains would have settled Melons out of doors, they did even Cucumbers. If resolved to try, we would advise having the ridge near to a wall or other fence, facing the south; give the plants but limited space to grow in, stop the plant when young, train to one stem, get the stem as soon as may be to the top of the house, and give it 4 feet of space, and at the top when the leaves, leave half a dozen at the top after shortening the shoot by tipping out its point, and the side-shoots from these buds left will most likely show fruit, which treat in the usual way. You are, however, more likely to succeed in the greenhouse. For this purpose sow in a hotbed, or a warm place, about the middle of April, in pots, and stop them when they are getting as needed, and strain a train as above, and by the beginning or middle of June the plants should be planted singly in 12-inch pots, using good loam for the purpose. These place in the house, and keep it at 60° at night, and provide the air is given early, it may rise to 75° to 85° or more during the day. The stopping &c., is on the principle that the Melon shows most freely on the third succession of shoots. There is not a Melon in all the list of our advertisers, but may thus be grown successfully; but remember, that for the time being, the greenhouse is turned into a hot-house. Thousands of places for the best bedding plants are sent to the Continent into tropical houses every summer. When growing freely give plenty of moisture, as you would do for Cucumbers; but keep rather dry when the plants are in bloom. Give more moisture and plenty of air when swelling, and keep it well watered rather dry, till the fruit begins to ripen. As to the root, you will need no pot or other support, or to prevent the fruit falling off when it is nearly ripe. Not long since fuller details were given.

NEW FUCHSIA (B. G. Hermann).—Your German friend, and many of our readers both here and abroad, are under a misapprehension on the subject of new seedlings coming "out" annually. Nobody but the owners of them can possibly know anything about them until they have been tried, and they, the seedlings, have been examined and passed by some competent judge. As that we know, therefore, of the new Fuchsias of the coming season, can only be from what we know of what the Floral Committee of the Royal Horticultural Society thought of them, that being now a recognised court of awards to seedlings about London, and as far as we can recollect, the following were the only three of the coming year which obtained first-class certificates from the Committee:—*Minnie Banks*, as the best white; *Comet*, as the best red; and *Mammoth*, as the best double Fuchsia.

ROYAL HORTICULTURAL SOCIETY (—).—We answered a similar question in our office. Write Mr. Murray, Assistant-Secretary, Royal Horticultural Society's Office, Kensington, London, W.

SEEDLING CIBERBARIA (W. and W.—B.).—Nothing novel, and petals are deeply notched.

LIQUID MANURE (Ignoramus).—Whether all the trees, &c., named by you will bear "a liberal supply" of house sewage, depends in a great measure upon the soil, drainage, &c. The Pampas Grass and herbaceous perennialis you mention will injure by an abundant supply. The others would not.

PLANTING A GEOMETRICAL GARDEN (S. E. L.).—Your planting is exquisitely good. Your regret at not being able to put more colours in, is the greatest praise you could give to the little plan. It is, often, by attempting more than the law allows that flower gardens are made vulgarised eyesores.

FRUITING GREENHOUSES OR CONSERVATORIES (Ignoramus).—For a greenhouse, except having a narrow shelf in front, you could scarcely do better than adopt some modification of the section shown at page 394. Or you might have a small border at the back for climbers with a shelf over it, a walk of 25 feet or 3 feet all round and a flat platform in the centre, or one raised in the centre and falling to each side. For a conservatory properly speaking, you could substitute a bed of earth instead of a stage. You do not give us height of back or front, nor yet what you would especially like. For varied purposes the stage or platform would be best. In a large house good variety of stages and platforms may be introduced; but for a length of 24 feet the simpler the arrangement the better.

LAMP FOR A WALTONIAN GASE (J. H.).—There is no lamp so good or more simple than the one which Mr. Walton himself uses, and which we described long since. The original lamp and the first Waltonian case ever described are now at full work in Mr. Walton's own garden at Sorbiton and nothing yet has answered better. But Mr. Walton uses a very simple street strength a very small flexible tube in one Waltonian case which stood in his

shop, and that seemed to us the most simple and safest way, and where gas can be obtained we would never use anything else for the Waltonian. But the gas is laid on at the front and the back of Mr. Walton's garden, yet he will have none of it, and never finds any trouble in trimming the lamp, which the gardener looks to.

PINKS, CLOVE, PICOETES, AND CARNATIONS (J. N.).—These are all hardy plants, but the kinds in most demand are so refined in their requirements that the very best thing that we can do for such of our readers as do not understand anything at all about Clove-pinks is to keep the names entirely out of sight, and advise them to begin with common border flowers of each kind from some one who supplies the open market. Ask for common double Pinks of three kinds of colours, also the old dark double Clove, the best of all the family, the flesh-coloured Clove, and the plain red; then three kinds of border Picoetes, and three kinds of border Carnations.

LEAVES OF CYCLAMENS (A. Rawson).—Many thanks for a sight of leaves so very different from the usual forms. No. 1, *europæum*, was never seen with a longer leaf; nor, so far as we know a persicum, No. 3, with such angles to the leaf. But No. 2, a true *neapolitanum*, is farther from all the different forms which the varieties of it produce than either of the others; the leaf being more in the form of those of the European *Asium* than that of any *Cyclamen*, besides being regularly toothed all round the edges. Such departures from the normal forms show how little faith can be placed on the descriptions of *Cyclamens* from the form of their leaves.

FRANS UNDER A GLASS (Querist).—Nothing more is required than to lift off the glass once daily to admit fresh air, and put it on again directly to keep the soil damp, not wet; to have the case in a moderately warm room, and all plants shaded from sunshine. All the species you mention are hardy enough.

THE ALANTHUS SILEWORT (A. J.).—If you apply to Mr. McGhee, Tyne Hall, Wford, Essex, he will supply you with eggs, and plants also. No other food will do well. Lady Dorothy Nevill's pamphlet on the *Alanthus* thorn will be ready by the end of the month.

POULTRY, BEE, AND HOUSEHOLD CHRONICLE.

POULTRY, &c., SHOWS.

MAY 14th and 15th. TATTON AND SOUTHSEY. Sec., Charles Ballance, Esq., Tatton.

MAY 27th, 28th and 29th. BATH AND WEST OF ENGLAND (City of Wells). Sec., S. Piman, Esq., Manor House, Taindon. Entries close May 1.

JUNE 4th and 5th. BEVERLEY AND EAST RIDING. Sec., Mr. Harry Adams.

SHELTER FOR FOWLS.

JUST recovering from a severe attack of influenza, and sneezing along perished with easterly wind, in that happy frame of mind which now and then occurs when a man really will quarrel even with his bread and butter, we thought all at once of our fowls, and wondered we did not see them. We turned to their usual haunts, but not one was visible there. We did not seek long. The bitter cutting wind met us in our teeth, got into our neck, penetrated our clothes, took the measure of our waists (now alas! the thickest part of our body), and at last fairly blew us round. "Cannot face it," said we to ourselves. "Nor can the fowls," said Common Sense. "Much warmer this way," said we, when the wind was in our back, "So it must be for the fowls." Thus we got to imagine fowls thought as we did of the weather, and, above all, of these miserable winds we may expect almost without intermission for two months. As our minds became busy, our miseries disappeared, and we set to work with a will to discover the tenants of our yard. We had not much difficulty in finding them. Wherever there was a shelter, there were fowls enjoying it. We have two yards, but only one possesses a shed, and, like many more, we do not care to incur the expense of erecting one in the other. We, therefore, sought for substitutes, and succeeded as follows:—On the open space which forms our run we have placed a number of thatched hurdles supported in a slanting position by a prop. They have proved a success. They are very inexpensive, clean, and by no means eyesore. They are useful in the garden when the fowls do not require them, and any ordinary labourer can make them. Since we adopted them, much sneezing and cold have disappeared from our yards. It is unquestionable that with fowls as with human beings, sharp easterly winds are injurious to health, and that every effort should be used to neutralise their effects. With this view all openings to the east should be carefully closed, especially at night. The quantity and quality of food may both be increased, and a little stimulant given with advantage at times. The surface of the earth supplies no food, and there is little disposition to seek it. When it can be done, it is well to leave open the doors of stables, wood-houses, empty barns, and buildings of all kinds. The birds will use them for shelter.

Care should be taken to turn the faces of the rips in which hens are confined with chickens strictly to the west, and if the

hinder part has any crack, or does not fit close, let it be covered with an old sack or something of the sort. The hurdles we have mentioned are about 7 feet in length, and 4 feet in width.

HALIFAX POULTRY SHOW.

THE Judges were Mr. Foulds, Cawthart, near Preston; Mr. T. J. Charlton, Stanley, near Wakefield; and Mr. Challoner, Whitwell, Chesterfield. The following were their awards:—

GAME (Black-breasted Red).—First, J. Fletcher, Manchester. Second, J. Dods, Ovenden.

GAME (Brown-breasted Red).—Silver Cup, First, and Third, J. Fletcher, Manchester. Second, W. Windle, Padeham.

GAME (any other variety).—First, J. Fell, Adwalton. Second, J. Hodgson, Bradford. Third, H. Mason, Dringlinton.

GAME HENS.—First and Second, J. Firth, Halifax. Third, T. Dods, Ovenden.

HAMBURGH (Gold and Silver-spangled).—First and Special Prize, G. R. Tate, Driffield. Second, H. Beldon, Bradford. Third, J. Croven, Clayton.

HAMBURGH (Gold and Silver-pencilled).—First, F. Hardy, Bradford. Second, H. Beldon, Bradford. Third, R. Hemmingsway, Shelf.

SWEETSTAKES.

GAME COCKERELS.—First, A. Aylroyd, Darlington. Second and Third, J. Fletcher, Manchester.

DORINGS.—First, R. M. Stark, Hull. Second, T. W. Hill, Heywood. Third, H. Crossley, Halifax.

COCHINS.—First, T. Street, Liverpool. Second and Third, W. Holzaad, Lightcliffe.

SPANISH.—Prize, E. Brown, Sheffield.

ANY OTHER VARIETY.—First, Second, and Third, F. Hardy, Bradford.

BANTAMS (Game).—First, J. Crossland, jun., Wakefield. Second, C. W. Brierley, Rochdale. Third, L. J. Crossley, Halifax.

EXTRA SPECIES.—First and Third, T. Dods, Ovenden (Brown Red Game and Black Red Game). Second, W. Irvine, Ovenden (three Cochins-China hens).

CHIEF POINTS IN GOLDEN-SPANGLED HAMBURGH COCK.

WHICH is considered the chief point in a Gold-spangled Hamburg cock? Would you prefer first-rate ears and a black breast, or medium ears and a spangled breast? Does a hollow in the centre of the comb take from the bird's value, and would the judges take any notice of it?—AMATEUR.

[Much would depend on the judges. Yorkshiremen love a black breast; others detest it. A blush on the deaf ear is a serious defect, in our opinion a black breast is a greater; and a hollow in the centre of the comb is almost a disqualification, because all people and all countries unite in condemning it. If such defects as you have named are found in first-prizetakers, their position must be due to the fact that in a nation of blind a one-eyed man is king.]

LOOSE CROP IN FOWLS.

I HAVE a Dorking hen that has an enlarged crop containing a thick fluid, which runs out of her mouth when held up by the legs, and has a very disagreeable smell. She seems quite healthy in other respects, and takes her food as usual. Would you inform me what the disease is, and if there is any remedy for it?—AN OLD SUBSCRIBER.

[Every fowl after drinking will turn the fluid from the crop through the mouth if held up by the legs. But from the hanging of the crop and the unpleasant odour, this is a case of disease, and is known among old poultry wives as "loose crop." If she is put where she can get at no water, and is only allowed to sip a little three or four times per day, she will recover. The crop will not become less while she has as much water as she likes.]

THE CANARY AND THE BRITISH FINCHES.

(Continued from page 447.)

REARING AND TEACHING.

WHEN the hen feeds her young ones attentively, and is assisted by her mate, but little trouble is experienced in rearing them. Although some male birds are mischievous and require to be removed while the hens are sitting and rearing their young, yet the majority will help to feed them, and many cocks will do the greater part; indeed, cocks when they have once reared young will frequently feed all that cry to them. I have at present a Linnet which was taken from the nest and put in a

age with an old cock Canary, which fed it and brought it up without any other assistance than supplying it with proper food.

This food consists of hard-boiled eggs chopped up shell and all, with crumbled bread and mawseed; also, a plentiful supply of fresh green meat, as chickweed, groundsel, seedy shepherd's-purse, and the spikes of plantain when the seed is tolerably forward.

Here, perhaps, is a good place to give a caution respecting cleanliness, for the greater number of failures arise from the presence of mites—a small species of bug which hides in the crevices of the cage and in the nest. They sadly torment the old birds, especially the sitting hen, as they increase in multitudes during incubation, and either drive the hen from her nest or much debilitate her, though more commonly they completely suck the existence out of the young.

As a preventive, I would advise the previous examination of the breeding-cage, and if any appearance of mouldiness or minute white specks of a floury appearance are perceptible about the cracks or joints, either at once to discard the cage or thoroughly clean it, then oil all the crevices to saturation, and fill them up with flowers of sulphur.

Some fanciers have advised the use of the Persian insect-destroying powder, but I have no experience of its effect. My practice has been to give the hen a clean nest, when she sat to sprinkle some flowers of sulphur in the nest, which I have generally found to be efficacious.

In the rearing of Mules from birds of a different nature from Canaries, attention must be paid to diet, to supply the old ones with food more adapted to the habits of the young. As regards the Bullfinch, it should be borne in mind that he is strictly a vegetarian, though, perhaps, from his fondness for the kernels or seeds of berries, blanched or broken almonds would as well procure an acceptable addition to their bill of fare, as well as grocers' currants.

If an attempt is made to breed from the Sparrow, he being omnivorous, the addition of bread and milk or unsalted cheese might be advantageous. While the Chaffinch and Yellow Hammer eat no green food, and I believe it is very injurious to their young—indeed, in a wild state they rarely touch even seed if they can procure insects: consequently, they would require instead of green meat, such things as sweet milk curds, unsalted cheese, &c., to rear the young on. If it were possible to induce their parents or nurses to eat mealworms, these would, perhaps, prove the more natural food. This subject of proper food is one of the great obstacles in rearing Mules from these birds which induced me to offer these remarks.

When the young birds can feed themselves they should be removed from the old ones and placed in a cage by themselves, still supplying them for a time with the soft food until they are well able to eat seeds.

Some fanciers who pay much attention to plumage, have large cages made expressly for the young birds. These are closed all round except the front, which is of close wirework, the back and sides being studded with short perches just long enough for one bird to sit comfortably on at a time, which prevents their pecking each other and pulling out their feathers. Care must be taken at the same time to so arrange these rests, or perches, that when any bird sits on a lower one his plumage is not liable to be soiled by one above.

In respect to teaching or instructing the young birds in song, it is a common practice to keep a cock or two which are good singers and whose song and execution are admired, and from hearing which the young birds take their notes. But if it is desired to teach them any particular song, the notes of other birds, or to pipe a tune, then much care becomes requisite to remove them very early from hearing any other singing birds except those they are to learn from.

The song of the Canary bears much resemblance to that of the Titlark (*Anthus arboreus* or Tree Pipit of some naturalists), with some notes resembling the Skylark, and a few of the harsher ones of the Nightingale. So strong is the resemblance, that some persons have been led to believe that the Canary had no note of its own, and that its common song was really so composed and the effect of education. This is, however, a mistaken notion, the bird having the same song in its native wilds; but, like many other birds, varying to a certain extent this natural song, it is reasonable to believe it best adapted to their vocal organs, and they learn it more readily and sing it more willingly than any other. One instance will explain this better than much reasoning. A man of whom my father was in the

habit of buying Nightingales, had a Canary with which he had taken much pains and which sung the Nightingale's note to perfection. A gentleman had a young Mule which he wished the man to instruct for him in the Nightingale's song, which the man agreed to do provided the said Mule was sufficiently young and had no song of its own. The bird was sent and placed in the hearing of its instructors; but, what was the man's vexation the next morning to hear his favourite Canary singing the Canaries' song, which he had learned from the imperfect recording of the Mule (the first attempts of a young bird to sing are termed by fanciers recording), and which it now performed in preference to the less natural notes of the Nightingale. This anecdote will forcibly illustrate the necessity of placing such birds that are to be taught a particular song where they cannot by any chance hear their natural song. On this account the more successful rearers of singing-birds prefer removing them from their parents quite young and bringing them up by hand.

There is much variety in the song of various Canaries, particularly in the length of time they sustain certain notes, the number and variety as well as the power and clearness of the voice, though the song of all bears a family likeness.

Young Grey Linnets are often taken from the nest and reared by hand with much care. They are sometimes taught the Woodlark's notes—a song which is much admired among fanciers; the Woodlark being a bird not generally successfully kept in confinement, whereas the Linnet is a much harder musician, and will sing the plaintive melody of the Woodlark tolerably well. Many, too, are taught selected songs of their own species, an account of which I copy, with permission, from Mr. Hippin's description:—

"**SONG BIRD AND BATTLING LINNETS.**—Linnets are said by bird fanciers to possess certain properties of song, which are thus denominated:—Weeting, chowing (rough and mellow), feering, laughing, piping, rattling, scrigging, wyng, and whisking. The bird that sings sweetest is said to do his song in the finest key, and if he goes through his song without stopping, to lead and finish well. If he begins imperfectly, or stops in his song, it is termed a bad lead or finish. The birds are distinguished by the terms battling birds and song birds; the former, from singing matches, and being continually carried about to rooms where birds of a similar character are brought, become lavish and hurried in their song. The latter (which are better fitted to teach young birds, and are principally kept for that purpose) are said to keep good time, and are noted for the beauty of their song; and I may mention that a song-bird Linnet, the property of Mr. R. Moody, was lately sold for £10. I now proceed to the detail of song—the jerks. Of these, of course, I can only give a portion, and those the most approved at the time I went to hear matches sung. The following are the names of a few sung by the best birds:—*Tollie tollie chay, ic ic quake aweet; lug lug arch aweet; ter weel, &c.; tollie chou, ic ic quake chow; egip egip pipe chow; ogip egip poi; tue tue fee; tue tue eizzy; and a very rare old song, as an chay chawist.* Some birds do an objectionable song called the donkey, *ic an jab*; and some, after finishing with a jerk, end with *chite chite chite*. With, with good fanciers, would, notwithstanding that they did plenty of 'toys' (a term for good song), cause them to be parted with as cast-oids, lest they should spoil their nestlings, branches, and young Linnet Mules; they were, however, readily bought for battling birds, in which this defect of song was often passed over, provided they were spirited birds. I may just mention here the Linnet's calls, as they are sometimes named at the commencement or during the song. *Tollie, tollie, pew and poi*, and the chuckle; they are so plain that any one who has once noticed them would immediately recognise them.

The acquired song of the Linnet was obtained by the old fanciers by the selection of the best birds that could be found and the introduction of certain other birds, such as the Titlark, and some say the Wren, as teachers. Thus by degrees, and by means of nestlings, which blended portions of the songs of stranger birds with their own, certain properties of song became adopted which did not belong to the Linnet naturally; but this result was only effected after a long-continued series of experiments, extending over a number of years. Many of the improvements thus introduced have now been lost, owing to various causes, one of which is said to be the purchasing of the best birds by amateurs who have not cared about preserving the acquired song. This removal of the best birds from places where they could be heard had also the effect of discouraging

many of the judges, who thereupon ceased to be fanciers; and those who supplied their place have done so with inferior birds, so that our modern specimens would only have been looked upon as cast-offs in days gone by. A few, however, of the old kind of song birds are still to be found—such are those of Mr. Moody, referred to above, but the generality of the fanciers now-a-days are unable to appreciate them, as but few are capable of reading the jerks. Of the birds of the present day it must, however, be said, that if their song is not so sweet as that of the old school, it has, nevertheless, the claim of being the more natural.

"The hybrids or Mules are, in my opinion, the sweetest song birds heard. Like the Woodlark, their notes are flute-like in tone. The greater part of the Mules sold by bird-fanciers sing the Canary's song; but I much prefer those taught by good song-Linnets; and double and even treble the price of the former will be given for the latter.

"**SINGING A MATCH.**—For the benefit of the amateur and general reader, I will endeavour to describe a match. There are three kinds of matches—"ones and twos," "most and best," and (with song birds sometimes) "best only." The match most commonly sung is ones and twos. You will notice in the song I have given above, that it is sometimes separated into two parts—the portion to the comma counting one, and to the semicolon two; but each jerk must be perfect, or not counted. The first business is to select two scorers, who are supposed to be able to read the song of any bird, however fast he may sing—as a good musician does a piece of music played in quick time; and a referee, equally efficient, is also appointed. Having settled the terms of the match and the choice of situation, the birds' cages are hung up at the places selected, and the scorers being seated, each of them prepares to score the points in the song of the bird for which he is engaged, and also to watch that his opponent scores fairly. The referee keeps an eye on both scorers, marks any wrong scoring, and decides every disputed point. He also determines when the time is up, and directs the scorers to stop—an important matter, as one bird may be singing at the time and the other not. He then counts the scores, and declares the winner. The time for singing a match is usually a quarter of an hour. Where the stakes are for a large sum the scorers are, of course, very closely watched."

In Germany, many Bullfinches are taken from the nest and reared by hand. After each feed they are covered over to keep them still and attentive, and a tune which they are desired to learn to pipe is whistled or played to them distinctly once or twice after each meal.

Sometimes a bird-organ is used, but more frequently a small flageolet. Some birds have been taught as many as three tunes; but it is better to have a bird pipe one correctly, than to jumble three in one. It takes a long time and much patience to instruct them, and the owner of a piping Bullfinch should know the air it sings, and be able to whistle or play it over to it a few times after each moult.

The Bullfinch is a very amusing bird, easily tamed and often taught to sit on the finger and fly to the hand to be fed.

The Redpoll and Goldfinch are both occasionally taught to draw their own water, to open a box, or pull up a carriage for their seed. And Canaries and other Finches have been trained to perform many little tricks, as swinging on a string, to fire a small cannon, feign death, draw a carriage, and many other little antics.—B. P. BRENT.

LOSS OF A LIGURIANISED STOCK.

SINCE my communication to THE JOURNAL OF HORTICULTURE relating my successful attempt at Ligurianising my apiary, I have been a passive observer of the numerous articles that have appeared in the Journal since that period; but I have not been the less interested, more especially since the superiority of this (to British apiarists) new species is fully established. Being yet in my minority in this branch of domestic economy—a student, and not a teacher, consequently not in a position to promulgate learned disquisitions upon apiarian science, I thought I should shut act with befitting decorum by remaining silent, until I was fairly out of this "Italian wilderness," and could fairly give my opinion pro or con, upon those which ("AN OLD FRIEND OF THE BLACK BEE," somewhat indecorously designates) "yellow foreign scoundrels."

They are certainly very showy compared with their dusky

brethren, and I should say very gallant, from the intimacy which exists between them and the "adjoining establishments." But I am digressing from the "point" now in hand, which is this:—Having been six months in the "wilderness" above referred to, I began to feel somewhat weary of the monotony, so determined upon extricating myself and getting a view of the "peep of day," but what was my dismay to find the wintry clouds had totally obscured "that orb"—in other words, my Ligurian queen is numbered with the past, and I am yet in this Italian labyrinth. All appeared to go on well from the date of my article in the Journal until a few days since. More especially in the autumn, I purposely united her unto my weakest hive (albeit it was a good one), and during the autumn I frequently said it was the strongest hive I possessed, so surprisingly they increased. A few days since upon the change of weather, I feared they were not doing well; yesterday being very mild my suspicions were still further confirmed, and I determined upon solving the problem, so I extracted all the bars and nearly all the bees were gone (that is Ligurians), save a few robbers—no queen could I find; consequently, concluded she must have died during the winter. You can imagine my disappointment: I paid them unwearied attention upon every favourable opportunity, and I looked with no ordinary pleasure upon the coming season. Nought remains but to reconcile myself to this vicissitude of fortune, and if circumstances permit to try again, aye, and yet again.—S. AMEX.

SUPER-POSING.

AFTER forwarding the remarks on the above subject, which appeared in your last Number, I have seen "A. W.'s" description of the attempted uniting two old common hives with limited communication, and at this advanced period concur in the editorial conclusion that the lower will now become the stock. Had I two such hives as "A. W." describes I should at the end of the season have felt disposed to place the two bottoms together, after the advice of the very old bee-keeper, only driving up at once the inmates of the poorest into the other, or into an empty hive first, and then suddenly precipitate them into the upper, trusting to a much more satisfactory result being effected during the bewilderment consequent on such a proceeding than the prolonged skirmishes after the orthodox North-and-South fashion of the two sections of the apiarian union.

In that case the vacated comb could be turned to a similar good account, as described by me in No. 31, or more recently and fully by that excellent apiarian Mr. S. B. Fox on page 428.

It affords me much pleasure to learn that the "erroneous construction" "A DEVONSHIRE BEE-KEEPER" put upon my meaning "was anything but wilful," and, therefore, most cheerfully do I withdraw the hasty expressions recorded at page 180, and regretted on reading his explanation that such had ever been uttered, and most cordially, therefore, accept his proffered hand over "our little differences," in the hope that any diversity of opinion we may entertain on apiarian matters may never again lead to so disagreeable an interruption.—A RENFRESHIRE BEE-KEEPER.

UNITING BEES.

"A RENFRESHIRE BEE-KEEPER" having fulfilled his engagement by replying to Mr. Hood's appeal for information on this subject in an able article describing his mode of effecting autumnal unions, I now feel at liberty to keep the quasi-promise which I made in page 140, that I would hereafter explain the mode in which I had at length succeeded in inducing Ligurian and common bees to mingle amicably together.

As Mr. Hood inquires as to the best mode of uniting bees in bar or frame-hives, I will commence by describing the method which I have found the most advisable where both colonies are located in any of these improved hives, and in the same apiary.

Commence by puffing a little smoke under the crown-board, and shifting the combs and bees of the hive, containing what is supposed to be the inferior queen, into an empty box, keeping a sharp look-out for her majesty, and securing her as soon as she is perceived.* At the same time those combs destitute of brood, and with the fewest bees adhering to them, should be ab-

* She may be kept alive for a few days, in order to provide against an accident, by being placed with about a score of her subjects and a bit of barley-sugar in a small perforated box, or in a wire-glass slightly raised on one side to admit air, and kept in a warm room.

stracted, and the bees brushed from their surfaces into the box until the remaining combs are reduced to half their original number. The crown-board may now be replaced (or all the slides pushed in, if the hive be fitted with slides), and the queenless colony allowed to retain its place for the present. Next, let the apiarian perform the same operation on the stock to which the first is to be added, removing, as in the former instance, one-half the combs, but allowing the queen to remain with her bees on the other moiety, which should be placed in the centre of the hive. The space on either side should then be filled-up with the combs and bees from the hive first operated on; stragglers brushed out, and the crown-board placed quickly over all. This operation should be performed in the middle of a fine day, when I have found it uniformly successful.

In order to recruit the population of my weakened Ligurian stocks and numerous artificial swarms of the same species, I last autumn collected all the condemned bees of the common species which I could meet with within a radius of five miles of my apiary, and having removed their queens, I, in the first few instances, introduced them to my Italian colonies* in the manner described in pages 45 and 46 of "Bee-keeping for the Many." I soon found, however, that this plan was altogether a failure † when applied to different species of bees, and am indebted to Mr. Langstroth, the American apiarian, and to my friend Mr. S. B. Fox, for hints which have resulted in such perfect success that I now take no thought for the safety of the Ligurian queen, beyond removing her adversary before introducing bees of the ordinary species.

My most recent and successful plan is to bring home my driven or "beat-out" bees, as they are termed by our Renfrewshire friend, in a common hive tied-up in a cloth, and being put in a dark place they are there left until the middle of the next day, when a little smoke is blown under the crown-board of the Ligurian stock to which they are to be united, after which it is removed and the hive temporarily deepened by a square frame, 1 inch to 1½ inch in depth, placed upon it. The bars and interstices between them having been liberally sprinkled with sugared water ‡ scented with peppermint, the straw hive is turned up, and the cluster of common bees, having been saluted with a few puffs of smoke and liberally sprinkled with the aforesaid mixture, are knocked out upon the exposed bars of the Italian stock. All that now remains to be done is to replace the crown-board as rapidly as possible, and the next day the square frame may be removed, when a peaceful union will be found to be the result.—A DEVONSHIRE BEE-KEEPER.

RAPID MULTIPLICATION OF LIGURIAN STOCKS.

I RECEIVED last summer from our worthy friend, "A DEVONSHIRE BEE-KEEPER," a stock of Ligurian bees and one queen. From the stock I had a late swarm, which leaves me at the present time in possession of three good strong stocks.

Reading a statement in the JOURNAL OF HORTICULTURE from S. B. Fox, of one of the hives in the possession of "A DEVONSHIRE BEE-KEEPER," that nine artificial swarms were created. Would either Mr. Fox or "A DEVONSHIRE BEE-KEEPER" be so kind as to state what period elapsed between the taking out of each comb; and, whether the bar was replaced with an empty comb each time, or was it only the bees upon the comb and brood in this single comb that were taken from the hive that formed a new colony, or were other bees added from another source?

I should also feel glad to hear their opinion, knowing their great experience in these matters. Would it be a safe plan to take a strong hive of the common bees and remove it some distance from its regular stand, then to take an empty hive and put into it one comb with brood and bees from one of my Ligurian stocks and place it on the stand where the common bees stood, so that the bees or part of them would return to their regular situation, and by that means strengthen the Ligurians? Would the common bees enter the hive and join the Ligurians?

* The Ligurian queen was in each instance secured until the next day in a small box over an orifice in the top of her own hive, from which she was separated by a divider of perforated zinc.

† It always resulted in an immense slaughter, and sometimes, notwithstanding all my precautions, in the death of the Italian sovereign.

‡ I do not participate in the objections to this process, which are entertained by "A RENFREWSHIRE BEE-KEEPER," as I find bees soon lick themselves and their combs quite dry after its application.

and in every case would an artificial queen be created?—A YORKSHIRE BEE-KEEPER.

[The dates of the nine artificial swarms referred to were given in page 97. In the eight first swarms, bees only were taken from the parent stock on the days indicated, brood being supplied from other hives; but quite an equal number of brood-combs were removed at different times, their places being supplied by empty combs.]

The presence of drones of the common species is the great obstacle to the success of the plan you describe, always supposing that the Ligurians are to be kept pure. We have tried to exclude them by means of a drone-stopper, but this is so great a hindrance to the entrance of the workers, that the results have been far from satisfactory to—A DEVONSHIRE BEE-KEEPER.]

BEEES DYING FROM DYSENTERY.

I HAVE lost two of my best hives, and my neighbour has lost one of his best hives in a very mysterious way, as follows:—They were in common straw hives, and have been kept quite dry all winter, and although they have now each of them at least 20 lbs. of honey in them, the bees have all died. They all had queens; but the inside of the part of the hive where they were was very dirty, from the fact of the bees having made their dirt on the part of the combs where they were. They have been supplied several times with clean floor-boards, but to no use. Of course the bees have not been kept up—that is, confined during the winter. My bees have a north aspect, and my neighbour's an east aspect.—A CONSTANT SUBSCRIBER.

Dysentery was probably the immediate cause of the loss of these three stocks. It appears pretty certain that this disease arises from confinement in a damp and vitiated atmosphere. We believe the best preventive is to be found in adequate external protection, coupled with moderate ventilation during winter.]

OUR LETTER BOX.

BRIDGING LARGE DUCKS (A Constant Subscriber).—It is always better to put your Ducks' eggs under hens; but doing so would be of little avail unless they were kept from the water. It is for this reason principally the hen is the better mother. The Duck drags her young about while they are so small and weak. She takes them under her feeding banks, and among tangled briars; their little strength is exhausted, and they perish. The large Ducks that are hens seldom see water, beyond the necessary quantity to wash in. Let a hen sit on Ducks' eggs in an old pigstye, or any shed where there is no water; and for three weeks after she has hatched let there only be a shallow vessel of water, not more than 1 inch deep. Feed on oatmeal curd, grass, gravel, tallow-chandler's greaves, and any scraps.

FOWLS PECKING EACH OTHER (H. A. H.).—All fowls will peck at a raw place, and all birds become carnivorous at the sight of raw flesh. This pecking is often lostered by meat-feeding. The Spanish seldom pick the cock's face, unless there is a spot or discoloration to induce them to do so; having tasted, they go on. But it is often caused by a bad state of body, and an entire change of food is the remedy. Fowls entirely debarred from green food, will seek for flesh as a substitute. If the laceration is extensive sew it up, there will be no scar. Let the cock be with the hens for an hour every day, and let him be watched that the hens do not damage his face. This is more than is required for breeding purposes.

CRUIVE OVER FOWLS (A Working Man).—As a generally useful fowl we consider the Cruive Crow far superior to the Golden-spangled, or any other Hamburgh. It is a bulky, crested fowl; plumage black, with a bronzy lustre on the neck and legs. The pullets make very early table birds. The hens are good layers and the eggs are large, but they are rarely broody.

FEEDING YOUNG CANARIES (A Subscriber).—The food for the old birds to feed their young or may consist of a mixture of hard-boiled egg, mawseed, grits, or shelled oats, and bread crumb, provided there is no alum in it.—P. B.

CATS (L. L. E.).—The book you allude to is "The Cat, its History and Diseases," by the Hon. Lady Cast. It is published by Croombridge and Sons, Paternoster Row.

LONDON MARKETS.—MARCH 3.

POULTRY.

The market begins to assume a clear look. Game has disappeared; Poultry becomes scarcer; and many of the fowls show the laying season has either commenced or is about to do so. Ducklings and green Geese come in scantily.

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last thirty-five years, the average highest and lowest temperatures of these days are 50.7° and 34.2° respectively. The greatest heat, 67°, occurred on the 12th in 1841; and the lowest cold, 17°, on the 17th in 1843. During the period 143 days were fine, and on 102 rain fell.

COCOA-NUT FIBRE REFUSE.

WITHOUT intending it I may have brought injury to some one; and I take the earliest opportunity of correcting an error, which I often committed by mistake, and I give it this promineny to atone for my seeming unfairness.

The good clergyman below Bristol, who first made known through this Journal the value of the cocoa-nut fibre refuse for Ferns and bulbs, tells me, in a letter just received, that he thinks that the writer at page 434 and your humble servant on cocoa-nut fibre refuse are both under a slight mistake. "I get mine from Bristol, and yet you have seen it and recognised it as the genuine article. I saw it produced from the crushing or tearing-machine preparatory to making mats and brushes, and so it is not the refuse from their manufacture, though I have no doubt the manufacturers have but one rubbish-heap for all the processes, so that there is a slight mixture of fibre with the sawdust-like stuff. I first saw it used (in Bristol) in the yard of a horse-auction, making a beautiful footing for the horses to exercise on. I at once saw it was too good for that purpose, and then came your article on its uses."

The grand discovery must, therefore, have been made by the clergyman at the same time as it was made in the Experimental Garden; and he deserves the more praise from having seen in his mind's eye how good it must be for various plants, while its goodness was only forced on our attention by the merest accident. The mills for the works were next door to the Experimental, and the stuff was used for mulching flower-garden trees and shrubs as the cheapest material we could obtain or think of. Every inch of the mulching was soon taken possession of by the most healthy roots you ever saw of Deodars, Cedar of Lebanon, and all sorts of Pinuses. That led to its use in planting such trees and such shrubs, which rooted in it faster and more strongly than in leaf mould. That being proved, it was next applied to recover the health of some very old trees which were great favourites, and which it did recover in a very remarkable manner.

There does not seem to be any godness in the refuse itself, as it were, but being always damp in hot weather, and free as feathers for the roots to run in it, they do take hold of it most greedily, and, of course, they must be new roots.* Our theory was this: Here is a stuff in which new roots come from the most unpromising stumps of old trees; and if you only can induce each tree to make roots at all, surely there will be no difficulty in feeding them from fresh soils and composts.

All this time the beds and borders of the flower garden were annually mulched with the stuff, and we could see flowering plants took to it as fast as trees, and a little of

it was used in potting flower-garden stuff. Just then a parcel of plants for the Experimental came up from Bristol way, and they were actually growing in this very stuff, and we owe to that rev. gentleman's practical knowledge all that we know of it for pot plants, and more particularly for Ferns and bulbs.

All the Ferns, and their allies, that I tried in it were different kinds of Lycopods in 1860, and lots of the new variegated *Pteris cretica albo-lineata*. I had forty plants of that one Fern sent to me before it was hardly in the London market, all little seedlings but six; and the seedlings in this cocoa-nut fibre stuff out of doors advanced so well last summer with me, that I had no fear of offering them to Mr. Eyles out of my open borders lest the frost should catch them. Another family, the fine new *Begonias*, were sent here by the dozen, and they, too, took to the cocoa-nut stuff in preference to the best compost.

So you see that all our experience of its uses in potting originated from Bristol. What made me say the refuse dust was made only here at Kingston, which was my great mistake, was this: The inventor of the process of crushing the nut was occupied in another patented process of a different kind next door to me some years back, and he told me his patent for crushing the cocoa-nut was for all England; but he has been dead three or four years, and probably the time of his patent may be run out, or a very different process may have been applied to the crushing of the nut-shells at Bristol; or the Kingston firm may let leases under the original patent, which is called after my old neighbour, Mr. Barsham, "Barsham's Patent;" but of the business part of the affair I know next to nothing. I only went once over the works some years since to see the crushing and the whole manufacture, and if anything I ever said ament cocoa-nut fibre refuse has done any harm to anybody, all I can say is that it was entirely unforeseen by me.

About Surbiton the cocoa-nut fibre refuse is being used for mulching flower-beds, borders, and window-boxes; but whether any one uses it for potting I never heard. But I have another string to my bow, which I must pull thus prominently, as if I were at match-targeting. All kinds of people from all parts of the country have been writing private letters to me about this stuff, and some even go so far as to ask me to turn out a pedlar, carry a pack full of cocoa-nut fibre refuse over my shoulder, and they would buy of me, get me customers, and provide me nights' lodgings, for all which I am grateful. But there are two great objections to that course: I am too old to carry much of a load, and peddling is down on the scale from what it was at the commencement of my journey. Another class of private correspondents suggest a sort of agency for me to buy the stuff at 2s. a-load, and sell it out in bushels to them and their friends. For that advice I am also grateful. But the truth is this: I have no time to spare for any mortal thing save my own experiments, and for short visits to shows and public places near London.

I have also an invitation from a New Jersey nurseryman, in the United States, to become one of his London

* Being vegetable refuse, by being kept moist it must give out slowly carbonic acid, and this gas is especially beneficial to plants when applied to their roots.—[Ed. J. of H.]

houses to deal with in plants, from having seen my way of packing to be, or had been, the same way as Mr. Bird's, of Stoke Newington, for his *Chrysanthemums*, and he says that is the only and really cheap and safe way of packing for the run to America. He, the New Jersey nurseryman, always packs for London as Mr. Bird does—that is, without pots, or balls, or baskets and mats, and they tell him his plants come fresh to hand; but that he never can induce the London trade to pack out of the old routine, and the consequence is, the expense is three times more than by his own plan, and more than half the plants are dead when they reach him.

Now, all our American readers will know that I am not in any way connected with trade in plants, save my own seedlings, which can only reach the market through an agency; for I could not trust myself to be agent for myself, much less to be one for the packing of plants for America, or for bushels of cocoa-nut stuff for our provincial markets.

Then, the next thing is to save our own office in London from the heavy postage charges for specimens sent us for identification from the mat and brush manufacturers. I think it necessary to state that the real stuff can be had only where the shell of the nut is crushed, and that I know only of the two places here stated—that at Bristol, and at the mills near Kingston-on-Thames. I think if Mr. Eyles approves of it in the gardens of the Royal Horticultural Society, the Society might sanction a sample of it being placed in their new conservatory on view, in order that Fellows and visitors to the garden, and to the Exhibition next summer, might learn to know it by sight. If so, I think that I could get the authorities at the Crystal Palace to do the same for their visitors, and thus to put it in a fair way of being known to all those who are bent on trying it on their Ferns, bulbs, and other plants. A sample also may be seen, I am told, at the office of this Journal, where any one may call and ascertain what is the true material by the evidence of his own senses.

The next is a very different subject, and one which goes somewhat against the grain. I am told in black and white of a "fact," that goes to prove "the present decay" of us gardeners from the attainments of a former race of florists. The gentleman writes this: "The following short extract will interest you;" it is from "The Dutch Gardener, by Van Ooeten, London, 1703." Speaking of the Sowbreads—the Cyclamens, he says, "There are several sorts—there is a double white one which bloweth in the spring, and is much esteemed, and it's said to have been brought from China; yet I believe it got from seed." I suspect, the gentleman remarks, Van Asten is speaking of the Cyclamen persicum; but it is interesting as confirming our old friend Gilbert's statement of the existence of the double sorts—a fact that our present gardeners deny. It is rather an interesting little work, and has some good ideas. It gives directions for growing dwarf pyramid Apples and Pears—the one on paradise, the other on Quince stocks. This would interest Mr. Rivers. But how will it interest breeders and the cross-breeders of the present day?

I confess myself to be entirely ignorant of the mode by which the old florists obtained double flowers, and I believe no one can now point out the real way. I look on the production of double flowers to be the end of a tether in one style of cultivating plants; and I hold it as a "fact" of the want of decay in the art of cultivation, that when cultivation emerged from the rule of thumb, to assume the natural or scientific practice now so far on the march of progress, the change was inimical to the production of double-flowering seedlings; that, like the variegation of plants, about which we have been so long and so far out at sea, the cause of doubleness was not owing to the superior cultivation of the parents, but to a long course of very unnatural way of growing plants, so to speak. All these changes I hold to have been brought about under conditions which were not natural, or likely to bring out the vigour of the parents in a natural way. I hold, also, that there was nothing accidental in the cause why double flowers or variegated leaves have been, or still are produced; that the result was owing to a sure and certain law, which would be now just as sure and certain in its results if we did not know it. And although I hold that opinions which are not backed by experiment are of little worth, I shall give my private opinion on how double flowers have been formerly obtained, without putting more stress on it than if I had never given the subject a thought.

It has often appeared to me, then, that the parent plants of double flowers have long been under a course of high cultivation

wrongly applied, if you can understand how that could be; but I shall explain by a reference to what is now very common. A fruit tree is bought and is cared for in the highest degree of cultivation, and the consequence is an immense deal of wood and very little fruit. The system is changed; lighter soil, less roots, and the lesser number of them more near to the surface—that causes a check, and fruit-buds come instead of wood ones. Then the high state of culture wrongly applied, which I assume did the same thing at the same time, stimulated the vital powers, and at the same time curbed that power unnaturally, and that brought about the derangement in the progeny which we see in double flowers. And the practice was on this wise: The composts were then of the most stimulating character, and the application of them was exactly the reverse of what is now practised. Neither pots nor borders were then much drained, and all the compost was sifted to the finest mould. Turn to that system, and in time it will do as formerly. D. BEATON.

NOTES ON VEGETABLE CULTIVATION.

(Continued from page 456.)

CARROT.—Although there is reason to believe the parent of the cultivated Carrot is an indigenous plant, yet it is far from being so hardy as some that have an origin in a more temperate climate. Be this, however, as it may; certain it is that the young seedlings are more liable to attacks from insect and other depredators than most other plants we have, especially when they are sown in the rich soil of most gardens. The soil best adapted to the Carrot is an open sandy one, deep, and not of that pernicious kind called a hungry sand. Such soils as we often see by the margins of some rivers suit Carrots best, the subsoil not being that dry impenetrable gravel so common on dry soils. The varieties best adapted to the garden are Early Horn, or its improved offspring the French Horn. James' Scarlet is also reported to be a good Carrot of an intermediate class; and the long Orange, Altrincham, or Surrey for late and general supply. But the Horn Carrot is esteemed the best, as containing least of that central pith or hard indigestible substance which comprises so much of the long varieties; the red or outer crust being the most valuable part of a Carrot, and the variety containing the greatest amount of red substance is the best article for table. For early use sow in a hotbed the middle of January; thin duly as they advance, and, as most families like them when not much larger than good Radishes, the thinning may be done by degrees. An early out-door crop may be sown on a warm border the first week in March if the weather permits; but the main crop need not be sown until the middle or end of April. Shallow drills about a foot apart will do, taking care to look sharply out for slugs and other enemies in a week or so after the seed is sown; and if you have any reason to expect these enemies scatter the ground over with soot and lime, which will keep these destroyers at bay a few days—perhaps until the young plant be able to get out of the way. Thinning and the other features of their culture, it is presumed, are understood by every one.

CARSCUM.—Although not generally ranked as a vegetable, still as an article often grown in the kitchen garden it is worthy of a notice here. There are many varieties of this article, some more for ornament or novelty than use; but we will only allude to the most commonly cultivated kinds for pickling and such purposes, and would say that the earlier these can be sown and reared the better. Sow, therefore, in a pan or pot in a hotbed in January, and keep them in that place until May, pricking-off and potting as wanted, and, after gradually hardening them off, plant some out against a sunny wall in June. Others had better be planted under glass on a rather poor soil not too deep; and if with a hard impenetrable bottom, so that the plants will receive a check when they reach it, so much the better. Those against walls ought also to have their roots cut with a spade if they show symptoms of becoming too gross, as it must be borne in mind the continued growth of the plant is against its ripening the fruit then on it. The old small Red is the best bearer, and for general uses the most convenient.

CELERY.—Certainly this is a British plant whose habits are well known, growing most abundantly on the salt marshes by the sides of tidal rivers and similar places, but by improvement in cultivation the rank flavour of the original has given place to one of a more delicate character. Notwithstanding the long array of names some seedsmen prefix to this article, there are in

reality but few distinct kinds, the old-fashioned designation of Red and White Celery being perhaps all that is needful to know. The qualifications of a good kind being solidity of stalk, free growth, not liable to run to seed, and a delicate crispness free from all approach to stringiness. Now and then new varieties named after some celebrated grower are offered to us as possessing these qualifications, which in turn are superseded by somebody else's still superior article. In the matter of decided improvement I have no hesitation in saying that Celery has certainly advanced more than many things the last twenty years, the specimens of hollow-stalked Celery being fewer now than at that time; and as names change so often it is needless here mentioning any, but I will at once proceed to the cultivation. Sow for the first crop the first week in January in some box or pan, which place in a hotbed; and when the young plants are up large enough to handle, prick them out into other boxes or pans, which in like manner place in heat again. This sowing will most likely furnish sufficient plants for early purposes; and the main crop may be sown about the middle of March on a slight hotbed, the mould being 6 inches thick and the surface made fine. Some spare lights, if they can be spared from other places, will be useful in protecting and encouraging the young seedlings, but sometimes they will do very well without. Prick out the young plants when convenient to handle into some good well-prepared bed, and at the proper time they may be planted in the trenches. The mode of doing this has been so often explained, that it is only necessary here to say that do not by any means dig the trench too deep, or, if so, be sure that the plant has still plenty of good material to grow in; for to dig a ditch as deep as the cultivated soil, and then dig in some raw dung into an obstinate unfertile subsoil and plant immediately is very bad practice, and is the cause of so much Celery running so many weeks in summer without making any progress. Subsoils require fertilisation, and until that is done the roots will not occupy it. Do not be too hasty in earthing-up, although the mode of putting that off until the plant is nearly full grown is not to be recommended. A little earthing in dry weather is beneficial. Celery is one of the gross feeders, drinking in large quantities of liquid manure like a toper. It, however, benefits much by it, and during the growing season may be treated thereto with advantage. Avoid the neighbourhood of trees, and as soon as the ground is clear dig it immediately for other crops.

J. RONSON.

ROYAL HORTICULTURAL SOCIETY.

MARCH 4TH.

FRUIT COMMITTEE.—Mr. Eddonnds in the chair. Prizes were offered at this Meeting for the best and second best three dishes of any variety of dessert Apples. The same for kitchen Apples, dessert Pears, bunch of new Grapes, bunch of late Grapes, and dish of Strawberries. In the dessert Pears, early Grapes, and Strawberry classes there was no exhibition. The first prize for dessert Apples was awarded to Mr. Hall, gardener to Captain Tyrrell, of Fordhook, Ealing, for Fordhook Bellefleur, Blenheim Pippin, and Golden Russet; and the second to Mr. Cunningham, gardener to the Bishop of London, Fulham, for Ribston Pippin, Scarlet Nonpareil, and Ord's Apple. In kitchen Apples, Mr. Cunningham was first with Northern Greening, Norfolk Beefing, and Winter Greening, or, as it is generally called, French Crab.

In Class E, the best bunch of late Grapes, any variety, there were three competitors. Mr. Tillyard sent a magnificent bunch of Muscat of Alexandria; and Mr. Hill, of Keble Hall, sent one of Lady Downe's Seedling. Both of these were very beautifully preserved, not a shrivelled berry was to be seen on the bunches, and the stalks were as fresh as they were the day they were ripened in August last. Mr. Tillery, of Welbeck, sent two very large bunches of Trebbiano, which were in capital condition, but were shrivelled, and very richly flavoured. In consideration of the fine condition of the exhibitions of Mr. Tillyard and Mr. Hill, they were each adjudged a first prize; and in consideration of the size of the bunches and rich flavour of Mr. Tillery's, the Committee awarded a similar prize to them.

Mr. Pottle, Little Bealings, Woodbridge, Suffolk, sent a dish of early Potatoes, grown in the open air in the Suffolk Crag. The tubers were planted on the 17th of October. The Committee highly commended this exhibition, and voted to Mr. Pottle the Society's Certificate.

FLORAL COMMITTEE.—The business of this Meeting was more of a routine description than of a floral display. Six new mem-

bers of the Committee had to be initiated and installed in the room of the six of the Committee who went out by rotation at the recent anniversary meeting of the Council of the Society by whom these changes are managed under the bye-laws of the Society.

A most welcome proposal was made to the Committee at their last sitting by a gentleman in the city, who offered to give a prize of five guineas for the best collection of dinner-table decoration plants, all standards, and all in pots not larger than 6 inches in diameter—that is, common No. 32-pots; the stems of such standards and the height of the pots not to exceed 21 inches. But the details were reserved for the consideration of the Floral Committee, and were now decided on as follows:—

Twelve kinds of standard plants to be a collection. The pots not to exceed 6 inches in diameter, and the height of the pot and the stem of the standard plant not to be under 20 inches, nor above 24 inches. The plants to be ornamental either in their flowers, their fruit, or their foliage. To this we would suggest, that four out of the twelve plants be in fine bloom, as many in fruit, and the remainder in beautiful and striking foliage—such would be an additional claim to the award. It was at first suggested that exhibitors should be at liberty to screen the pots in any manner their own taste might dictate; but that suggestion was rejected by the Committee, as tending to limit the competition to the neighbourhood of the metropolis, while the Committee expected from the great country party a more free expression of the dash and bearing of their family dinner-decorations when at home in the provinces, where the flower-pots are more commonly sunk in solid gold or silver vessels, than in any temporary screens or flimsy ornaments. And we may add, of our own knowledge, that the Committee were led to this point from the exhibition of so much of the plum-pudding style of the desert competition at the opening of the new gardens. As much as to say, Let us first get this grand idea fairly afloat, and then it will be sufficient time to discuss the screening portion of it. The time for this competition was also changed by the Committee from July the 2nd to some day in September, probably in order to have a better choice and chance of plants in fruit.

Among the new flowers exhibited were two which obtained First-class Certificates by the unanimous votes of all present. The one is the finest species that has yet been seen among the Cattleyas, and is named *Cattleya amethystiglossa*, a surname which sufficiently indicates the richness of the curved labellum, while the sepals are richly and evenly dotted with purple spots all over a flushed carnea ground-colour. It was sent by R. Warner, Esq., of Chelmsford.

The next was *Salpigophora chilensis*, sent by the Messrs. Veitch, supposed to be hardy, and appearing to the best practical judges present to be a free-blooming plant, and, likely to bloom in the autumn, when it comes to its natural elements. The flowers are of a rich rose purple, but small for this family. The growth and looks come nearest to those of *Tecoma* or *Bignonia jasminoides*.

Mr. Wm. Paul, of Waltham Cross, sent a large collection of cut Camellias, for which a Special Certificate was given. It contained amongst others, *Princessa Bacchiotti*, crimson with white strips, very fine; *Eximia*, fine; *Elater*, large variegated rose, very much like *Maesta Rosa*, but somewhat more pointed in the petal; *Fæstii*, very fine and large; *Fimbriata*, *Donckelaarii*, and many other fine sorts in good condition.

There was a small *Laelia* from Mr. Williams, more fit for the herbarium than a floral committee; but there was a highly interesting single Violet, and a cross-hybrid between a garden Stock and *Mithiola sinuata*, from Captain Trevor Clarke. The Violet is said to be the single form of the common double Neapolitan Violet; and a new race of Stock with a more hardy constitution than any of the present race is expected from this hybrid Stock, of which we believe Mr. Eyles has received a plant to be proved at Chiswick.

From Mr. B. S. Williams, of Paradise Nursery, Holloway, came a very pretty variety of *Cypripedium barbatum*, which received a Label of Commendation.

THE LARGEST APPLE TREE IN AMERICA.—A correspondent of the *American Agriculturist* says that on the farm of Peter Kohler, Lehigh County, Pa., there is an Apple tree which, by actual measurement just made, is 17½ feet in circumference, 1 foot above the ground. At nearly 7 feet high it is 15½ feet

around. It forks at the height of 7 feet, one branch measuring 11 feet 2 inches, and the other 6 feet 7 inches in circumference. The tree is 51 feet high, and the branches extend 36 feet each way from the trunk. An old inhabitant, of the age of ninety-three years, says the tree is over a hundred years old. It still bears every other year, the crop last year being about forty bushels of sweet Apples. Can any one excel this?

CULTURE OF HERBACEOUS PERENNIALS.

(Continued from page 162.)

CUTTING-DOWN.—As some of the flowers bloom early in the spring, others in early summer, and so on through the season, the dying flower-stems should be cut down as soon as the bloom is over. Nothing looks more unsightly than decaying flower-stalks. Even if the stems bear seed, they in that state are not ornamental; hence, not a day should be allowed to pass over after the flowers fade before the old stems are cut down to the ground, and also all the decaying leaves. Young leaves will then grow, and the plants though not in flower will, at least, appear green and slightly. Some, indeed, such as bulbs, will need to be nourished to the last as long as the leaves continue green, in order to lay up a store of sap in the bulbs for the following year; but these are exceptions easily remembered. The generality will bear cutting-down close to the ground leaves, and will be all the stronger for it the next season.

PROPAGATION.—There are several ways of propagating perennial hardy herbaceous plants—viz., by dividing the roots, which is the most common, by suckers, by seed, by cuttings of the flower-stems, by root-cuttings, and by piping. The names of the different modes all indicate sufficiently the way they should be done; however, it may be advisable to briefly describe each.

BY DIVIDING THE ROOT OR PLANT.—Take up just after flowering any plant that will increase by this method, and divide it with a strong knife into good-sized sections. Take away the old soil, and replace it with fresh of the same kind; then plant a strong section in its place, and the rest in a nursery-bed, either to supply deficiencies, or to exchange with some other cultivator.

BY SUCKERS.—Such species as throw up suckers may be increased very easily without disturbing the parent plant. Bare the sucker a little way down till roots are perceived, then cut it off below those roots, and immediately plant the suckers in a shady border for a year, when they may be transplanted into the place where they are to bloom.

BY SEEDS.—Some species do not propagate readily by the ordinary methods; hence it is necessary to allow a stem or two to produce seed where increase is desirable. If the seed ripens by the middle of July, it may be sown immediately in the same kind of soil as the parent plant delights in. The seedlings may remain in the seed-bed till spring, and may then be planted out in nursery lines for a season, and afterwards transplanted to their final home; others that do not ripen till March or April, and then sown in beds, and when strong enough, planted out and transplanted as directed above for such as are sown in the same year.

BY CUTTINGS OF THE FLOWER-STEMS.—When this mode is adopted (and it is applicable to such plants as double Scarlet Lychnis, double Rockets of sorts, and others), it is better to sacrifice one or more heads of flowers just as they are coming into bloom. Such stems have fresh leaves on them; cut them into pieces about 2 inches long, divest them of their lower leaves, and then prick them out in sand, and place a hand-glass over them shading from hot sun; they root readily, and form a plant out of the top joint of the cutting. Such plants require planting out in the reserve garden for a season, and to be prevented from flowering, in order to make strong blooming plants for the border the second year.

BY ROOT-CUTTINGS.—The common Mint affords an example of this mode of propagation. Such plants send forth underground runners, and these runners are full of eyes which, when the stolons or creeping roots are cut into lengths, start up shoots which quickly make excellent plants. This mode may be done at almost any time of the year; but the best time is about the end of May, because then the young plants become well established before winter. Plant the cuttings out in rows in the reserve garden, and transplant them where they are to bloom the spring following.

BY PIPINGS.—This way is used for plants that have jointed stems, of which the Pink furnishes us with an example. This mode is well known to florists, and is performed thus:—With a sharp knife cut off as many pipings as may be required, dress off all the lower leaves, leaving four or five at the top. Let these be left entire, and then plant in sand under a hand-light behind a shady wall until they begin to grow; then lift off the hand-light, and when they are sufficiently rooted plant them out in a nursery-bed for a year, allowing no flowers to be produced; they will then form good plants to transplant where they are to bloom.

SELECTED LIST.

Arranged according to the time of flowering, colour, and the height they attain when in bloom.

FEBRUARY.

- Red.*
Cyclamen coum, 3 in.
Helleborus niger, 9 in.
Yellow.
Eranthis hyemalis, 3 in.
MARCH.
Red, Scarlet, Crimson.
Hepatica americana rubra, 6 in.
Cyclamen europæum, 3 in.

WHITE.

- Hepatica americana alba, 6 in.

HODGIN'S BROAD-LEAVED HOLLY.

MR. FISH (see page 359), in THE JOURNAL OF HORTICULTURE, writing of the Trinity College Gardens, Dublin, says, "We have no recollection of seeing this variety before." It is much to be regretted this fine evergreen is not more generally known. Perhaps the dimensions of half a dozen of our plants may be interesting to your readers. They are all pyramidal plants on turf, and clothed with foliage to the ground.

No.	Height.	Width at base.	No.	Height.	Width at base.
1.	19 feet.	20 feet.	4.	15 feet.	17 feet.
2.	18 "	17 "	5.	15 "	18 "
3.	16 "	16 "	6.	14 "	13 "

The above are a few selections from many plants we have in the pleasure grounds here. It is very strange this variety should be so little known. We are frequently asked which Holly it is.—WILLIAM HILL, Keele Gardens, Staffordshire.

PEACH BLOSSOMS FALLING.

WHAT is the cause of my Peach blossoms falling off? I planted four years ago Peach trees at the back wall of a large greenhouse, 35 feet by 15 feet. The border in which they are planted is 5 feet in width, from the wall to the return-due. The border is made up of the best material, in which the trees have done well, having fine healthy wood, and at this moment are covered as with a sheet of bloom. Last year all the bloom fell off without one fruit setting. I am afraid of the same failure this year. There is a table stage in front 3 feet high, but the plants are low, and I think do not interfere with the trees on the wall.—PEACH.

[High plants on the stage by shading would prevent the wood hardening, and though there might be plenty of bloom it would not be perfect. If your plants are low this would not be the case to such extent. We think very likely the border was rather dry when the buds dropped last year. Examine now and see, not the surface merely, but to a depth of a foot or more. If dry, make holes and water at about a temperature of 70°, but do not saturate; let the water be given gradually, a little at a time, and two or three days between the waterings. A saturating all at once, if dry previously, would cause the very effect you wish to prevent. Lastly, if all the border is right, or made so, to make doubly sure, thin out the blossoms well where so very thick, give a little air every day, plenty when the weather is mild, and as an average keep not above 50° at night.]

MANAGEMENT OF OLD ORANGE TREES.

TRENTHAM ROSE GERANIUM NOT BLOOMING.

IN THE JOURNAL OF HORTICULTURE of August 13, 1861, *Flora* was promised further information about the management of Orange trees in boxes. The instructions then given were followed out. As much of the old mould was removed as possible, without giving a general shift, and new soil added. The mould taken out was caked and full of worms, but the plants do not look better for the good soil; the leaves are colourless and shrivelled. The trees are old, 8 feet high, in circular tubs 6 feet in circumference, and 1½ foot high. The old tubs being rotten, new ones have been made of the same height, but 7½ feet in circumference. Is this the proper season for the shift to be made? and what degree of heat will they require after-

wards? The trees are grown in a conservatory. There is no vinery to place them in after they have been shifted. How can they be managed in the conservatory?

Flora also wishes for some hints about the blooming of the Trencham Rose in beds. Last summer they were all dead instead of flower.

[If the soil was really so bad as you describe and full of worms, the less that was left of it the better. You do not say what the state of the roots is; but if well done with sweet fibry soil, they might do it carefully watered—that is, the soil not drenched until roots were working in it. The roots will suffer nothing from being carefully deprived of old worn-filled soil if they are rightly managed afterwards. Even if washed of all soil whatever it may be in the favour of the plants; and if allowed thus to absorb for ten minutes, the plants will need more syringing of the head than waterings at the root for a week or two.

We have answered the note before receiving specimens of the leaves. If only a few are so pale they will get over it, as the leaves are a good size. If many are so pale it shows that the roots are in unhealthy soil, and too much water given them for the heat. When kept cool in winter the soil should be dryish. In a healthy state we would expect plants to shed a few such leaves.

If the Trencham Rose Geranium makes so much foliage, give it poorer soil or plant it very shallow; and if that is not enough, cut the roots. With us it blooms splendidly if merely planted.]

GAS IN HOT-WATER PIPES.

I USE one of Mour's boilers for heating the hot-water pipes in my greenhouse. A three-inch T-piece supplies two four-inch flow-pipes, and there are two returns, one either side of the boiler. I have been much troubled with air in the pipes, which though let out at taps placed on purpose, accumulates so rapidly when the fire draws keen, that in a couple of hours afterwards a considerable quantity of water will, if not prevented, boil out, returning through the supply-cistern which feeds the boiler at the bottom of one of the feet. To avoid this difficulty I have had a three-eighths pipe tapped into one of the flow-pipes running up 2 feet above the top of the supply-cistern. On turning the tap at the top of this pipe last night to let the accumulated air out, I placed a taper I had in my hand to the current of air to see if it were sufficiently strong to blow the light out, when the gas (hydrogen, I suppose) ignited, burning with almost a pure blue flame. Are the iron pipes becoming oxygenised?—JUNIOR.

[It is quite likely that the pipes may become oxygenised, but without more proof we cannot be certain as to the gases. Why not relieve yourself of all doubt and uncertainty in the matter by taking your taps and using them for beer-barrels, and take a small gas-pipe right outside the house, and leave the mouth open, bending it down to prevent the dust getting into it?

There is little the matter with the Camellia leaves you enclosed. They may have had a scorching when the points of the leaves were damp. The simplest shading would be thin calico or muslin furnished with rings to hook on and off when desirable.]

TRENCHES WITHOUT MANURE.—Dig, first of all, a trench 10 feet long, 5 feet wide, and 20 inches deep. This trench forms the bed for the materials. If, however, you wish to raise the bed above the level of the soil, you can, with some stakes and old boards, build a kind of box which will hold it. This done, we strive to collect together on the spot the necessary materials to construct the bed itself. Procure, first, 300 lbs. to 500 lbs. of straw, or of old hay; or it may be of litter, or of well-dried moss. Second, 1½ to 1 bushels of powdered quicklime. Third, 1 lb. of ozs. muriatic acid, diluted in 20 gallons of water. Fourth, 1½ lb. of saltpetre, dissolved in 27 gallons of water. Fifth, a new broom, or one nearly new. Spread over the bottom of the trench a layer of straw, or whatever the material may be, about 8 inches or 10 inches thick; sprinkle it with the quicklime; dip your broom into the vessel containing the muriatic acid diluted with water; then sprinkle this first layer, after which you must make a second one of the same thickness. You scatter upon it the lime, and sprinkle the diluted muriatic acid in the same manner as before. Make at last a third layer of straw, of less thickness than the first two—say 4 inches or

6 inches only, and wet it with the water in which you have dissolved the salt-petre; but shake up the bed often, and pour it upon it, so there may be absorption by the lime, which will evaporate a good part of the liquid in parting with the bed. After this operation, the frame can be placed upon the bed, a few inches of earth spread inside, and as soon as the extreme heat has subsided, which will be in two or three days, it will be ready for use. Beds formed in this way will maintain their heat from four to six weeks.—(*Revue Horticole*.)

LADY DOWNE'S GRAPE.

We have received from Mr. Thomson, gardener to His Grace the Duke of Buccleuch at Dalkeith, a bunch of Lady Downe's Grape, which is one of the largest of the kind we have yet seen. It measured 10 inches from the shoulder to the point, and had one large shoulder. The bunch was well set with large, round, jet-black berries beautifully covered with bloom. The crop has been hanging since September last, and the fruit is now as plump and fresh, with stalks as green as any new Grapes possibly could be. The fine trace of muscat flavour is quite distinct; and altogether this bunch is almost as remarkable an instance of skillful gardening as the Black Hamburgs ripened on the 1st of January, and which were noticed in the February Number of the *Florist* and *Pomologist* as "the most masterly example of Vine-forcing that has yet come under our notice."

From all we have seen of Lady Downe's Grape, we have no hesitation in pronouncing it one of the best, if not the very best, late Grape there is in cultivation.

CRACKING OF GRAPES.

A SUCCESSFUL experiment which I made upon the Chasselas Musqué variety of Grape the present season will indicate the remedy, and perhaps serve to explain the cause of the cracking to which this variety is peculiarly liable.

About the 15th of June, after the berries had attained their full size, and before they had commenced to colour, each bunch was carefully suspended from the trellis wires, so as to relieve the stem as far as possible of its weight; then, with a sharp, thin-bladed knife, an incision was made in the stem, with a sloping, upward cut, about three-quarters of an inch in length, and to the depth of about one-half the diameter of the stem. This checked the exuberant flow of sap to the fruit; the berries ripened perfectly, and hung upon the Vines, plump and sound, until the 15th of November.

This delicious Grape, which has no superior in flavour, has been banished from most vineries on account of its almost universal tendency to crack. When the Vine is grown in an inside border, and the watering judiciously managed, this may be sometimes prevented, although it not unfrequently cracks even when grown in pots. It would seem that the sap in this variety flows with unusual freedom, and with undue determination to the fruit; the skin being thin, cracking and bursting of the berry necessarily follow.

For its earliness, abundant bearing, and high musky flavour, this variety is worthy a place in every vinery, and will repay the small amount of time and care required to insure a perfect crop. It is called by the English Joslyn's St. Albans, and in America, Muscat Blanc Hatif.—JAMES MATHESON.—(*American Gardener's Monthly*.)

NEW BOOK.

IMPERIAL LIBRARY ATLAS.*—The first part of this work is just published, and the portion of England, the France, and the Switzerland comprised in it are excellent. The maps include all the new lines of railway; and being fully coloured, greatly facilitate reference by the readiness with which the boundaries of each county, department, and province can be appreciated. They are on imperial folio sheets of drawing-paper, and when completed will form a very handsome volume. They are prepared with great attention to accuracy.

Phillips' Imperial Library Atlas of the World, &c. By J. Bartholomew, F.R.G.S., and W. Hughes, F.R.G.S., &c. London: G. Philip & Son, 32, Fleet Street.

GARDENING IN BURMAH.

EXTRACT of a letter from Tavoy, Tenasserim Provinces:— "Preventions against frost are here unnecessary, but we have as much to guard against the scorching rays of the sun. This luminary must be carefully guarded against in the middle of the day, or it would as surely destroy vegetation here as frost would do in England. I am, of course, only speaking of plants introduced into this country, and forced into life and activity when other vegetation is in a dormant condition. We can only grow English vegetables in the dry season—November, December, and January; and at this time all the leaves in the jungle are falling, and the trees are quite bare until the beginning of May, when the monsoon commences.

"I have begun to raise a few things under my house ready to put out as soon as the monsoon has abated—such as Beetroot, Turnip-rooted Cabbage (a delicious vegetable), Cauliflower, &c. I get these plants about 8 inches or 10 inches from the ground, then put them out, as they can then stand a good storm of rain, which we generally have with thunder at the termination of the monsoon. I have adopted a novel plan of growing these plants. I have a strong plank with four small wooden wheels running upon two pieces of timber, so that I can push it into or near the direct rays of the sun, and then at night, or when it rains, I can pull it under the house. The seeds are sown in common packing-cases cut down, and they answer the purpose very well. By adopting this plan I procure things a month earlier than my friends in Moulmein. I have Asparagus now growing well in my garden, and intend trying Rhubarb and other things, many of which have never been seen in Burmah. Have you seen the Celery? It is the German Celery, and is boiled like Beetroot, and eaten with salad. Its advantage is that it is much more wholesome than Celery eaten in the raw state.

"I am now a member of the Horti-Agricultural Society in Calcutta, and procure almost all kinds of seeds of the finest description, especially vegetable. Many thanks for the seeds you sent me. I should be glad of some first-rate Fuchsia seed, or the seed of Myrtle. I think I have almost everything else I require. I am now growing a new kind of Dianthus, Roses, Statice, Gloxinias, Picotee, Cinevaria, &c.—indeed, I find I can grow almost everything I wish, although I had doubted if I should succeed with many things which grow as well or better here than in England.

"I have succeeded in budding Roses almost beyond belief. Some buds were put in about six weeks since, the same buds are now shoots 18 inches in length! and will soon be in full bloom. I much regret not having any Fuchsias; although I have sown seed repeatedly not one has come up. I received some excellent seeds from London, and amongst them some Fuchsias, but not one came up. Some seeds of Fulgens would be thankfully accepted, or of any other good kind. By the last mail I sent a sketch of my house, so that you will understand better how I can grow my plants, as I say 'under' the house. This style of building is most convenient in this country, forming a promenade in the wet weather, and is the coolest in the hot season.—*Tavoy, Tenasserim Provinces, Burmah, August 15th, 1861.*"

THE VERBENA.

A FAMILY so numerous as the one intended to be treated of, and which plays so extensive a part in the flower-garden decoration, may very justly be entitled to a separate chapter, especially as its cultivation is, perhaps, more widely carried out than that of any other species of plant now used in the parterre, and to meet the increasing demand propagators have industriously tried to supply us with an infinite variety of tints, all more or less good, so that the public taste has become very fastidious; and after trying and rejecting many new kinds of a merit that would have commanded great attention and a good price twenty-five years ago, they have in some instances fallen back again on old but discarded favourites. But as this is the age for seedlings, and new varieties when really good seldom fail to meet their deserts, we now and then meet with one which retains a good place in public opinion for perhaps a dozen years. Very many are lost sight of in less than the half of that time; and some encountering a snow storm from some exalted power on their entrance into public life, rarely ever rise above the misfortune. But the endless varieties that take their place puzzle all but the ardent cultivator who follows up the series of new kinds which year after year are offered to his notice.

Leaving, however, this part of the subject, let us see in what light the Verbenas were held years ago, when its varieties were limited to some three or four.

My acquaintance with the parents of the present extended group of bedding Verbenas commenced about 1830. *V. chamedrifolia* or *V. melindres* (for I believe they were identical) being the first of the family, and for some years was kept as a choice greenhouse plant tied up to a stick, and now and then favouring us with a truss of flowers of a more brilliant scarlet than anything with which we were then acquainted. The only regret being, that the habit of the plant did not conform to a better shape, the method of training at that time being in a great measure confined to upright tying. By-and-by, however, it was tried out of doors in a favoured place, and I well remember the delight it caused in a flower-border in the vicinity of a mansion, whose owner was one of the first members of the Horticultural Society. The summer being a fine one, it bloomed as well as I have ever seen Verbenas do since, and after supplying innumerable cuttings to the gardener of its worthy owner, as well as to many friends, it was thought worthy of a covering, and a low glass frame was made to fit the place it occupied, and placed over it before frost set in; and though the situation was one where severe frosts generally occurred, it lived the winter and flowered early the ensuing season, and its adaptability for flower garden purposes was thus established. This was to the best of my belief sometime about 1837; and about the same time, or before that, *Verbena pulchella*, another useful kind (and one which I use to a greater extent now than any other, except *V. Purple King*) was added to our lists. I am not certain whether this one, or *V. incisa*, a pink-flowered variety, came into notice first, but these two, with *V. venosa*, became pretty plentiful before 1840, at which time *V. teucrioides*, a white sweet-scented variety of strong growth, came before us with a high sounding name; and as a year or two before that we were favoured with a crimson variety of neat habit, called *Tweediana*, we became possessed of almost all the tints we thought could be had in *Verbena*. And although we had several additions the next few years, I do not think we had any really useful good kinds until 1845, when *V. Emma* again attracted attention to the *Verbena*, and the mixture varieties were again called into requisition, improved and sought after with an avidity which continued some years, but latterly has subsided into a more steady demand for kinds possessing distinct qualifications fitting them for bedding purposes.

Now, in the above historical notes on the *Verbena*, I by no means affirm that the dates given were the first at which the kinds mentioned were known: on the contrary, they might have been in the hands of the favoured few a year or two before that. Neither do I assert these to be the only kinds then known, but they were undoubtedly the leaders in the way. One of the most popular kinds about 1845 being *V. Charlwoodii*, followed by *V. atro-sanguinea*, which if still in existence is far from being a despicable one now. A pink under the name of *Beauty Supreme*, retained a place for many years, and I believe the "*White Perfection*" of the present day to be more than a dozen years old. But I will not attempt to follow up the advent of new varieties after 1845, or rather after *V. Emma* became common, for the name would be legion; rather let me point out some remarks to the uninitiated in the way of selecting from the formidable lists we now have the kinds best suited to adorn the flower garden.

It is needless here to say that the requirements of the times have called into existence a greater number of kinds, and a greater diversity of tints of colouring into the *Verbena* family than into any other that I am acquainted with, the *Dalilia* alone excepted—from white through all the gradations of pink, rose, scarlet, crimson, maroon, to nearly a black, with some also approaching blue and purple; and a clear bright blue will, perhaps, be forthcoming some day, certainly we have not got it yet. Yellow, unless bright and clear, seems not so desirable, although I hear of inquiries made that way, and last spring I had one sent me under the name of "*Welcome*," said to possess that colour, but it turned out to be nothing more than a sport from *pulchella*, and a very indifferent one, too—less of a yellow than many *Roses* and *Carnations* that have been called by that name. A much better yellow *Verbena* existed at least eighteen years ago under the name of sulphurea, but it was not of much account, and I can hardly bring myself to the belief that a yellow *Verbena* can be much of an acquisition, while a blue of the same colour as *Salvia patens* would be a boon. However,

setting aside these ideal wants, let us see which are the most useful amongst those we possess, and which kinds we ought to dispense with.

Notwithstanding the relationship existing between the florist and the extensive flower-gardener, there are times in which their views differ widely, and in the matter of the *Verbena* this is very often the case. The florist or exhibitor of *Verbenas* at a show wants a large truss of bloom, each individual plant being also large and bold, and very often with an eye differing in colour from the limb of the corolla: the whole to present a sort of Mushroom-headed outline, so that five or six such trusses may make a good-sized bunch capable of being examined closely, and their marking, or cloudings, if they be required to have such, may be seen to every advantage. The plant which produces these blooms may be as unmanageable as Couch Grass for anything the florist cares, so long as it produces blooms of the kind that will tell at a show. Now, this is widely different from the requirements of the flower-gardener who has studied the effect of *Verbenas* of various kinds in the flower garden, and the number of varieties approaching that standard of his wants is much less than many suppose—in fact, I confess that amongst some sixty or more named kinds, I have only two or three that approach what I want a *Verbena* to be in the flower garden. This, however, I will explain.

It being generally admitted that flower-beds are seldom immediately under the eye of the spectator—more often they are from ten to a hundred yards from him: consequently the flower, if composed of two distinct tints, becomes blended in one intermediate one, which, however, is sometimes pleasing enough, but in a general way is the reverse, two bright colours neutralising each other, and producing an uninteresting mixture differing widely from each. An example of this is recorded in a Number of this Journal, where a correspondent complains of a bouquet being found fault with that was composed of exactly the same colours as were admired in a bed at Kew Gardens—*Verbena Purple King* as a centre, edged with *Geranium Flower of the Day*. The complainant, making the bouquet of the flowers of both, was censured for doing so, while the bed was admired. A very little consideration would tell how this is accounted for—the flowers of the *Geranium* blended with their own leaves, and formed that pleasing tint or mixture which the flowers in the bouquet could not do alone: hence the objection to it. Now, the effect produced by a striped, clouded, lemongeared or white-eyed *Verbena* with the colouring of its other parts, is just such a mixture as the two colours would make when mingled together, and is often far from what is wanted or sought for. On the contrary, clear and distinct colours are preferable, and not such as require to be handled to be admired.

I regret my acquaintance with the latest varieties is not sufficiently extensive to enable me to give many examples; for of late years I have planted *Geraniums* more extensively than *Verbenas*, where *Scarlet* and the other colours that *Geraniums* represented could be made to do, and the result of the present season's experience has rather confirmed me than otherwise in the superiority of the *Geranium* for the many purposes of flower-gardening. In saying this I expect some one will be exclaiming, "Look at the gorgeous mass of bloom in so and so beds in August last." This I freely grant; but look at those same beds at the end of September if they be in the south-eastern counties in a dry situation, and have not been supplied with water. Even with all this assistance they would be inferior to the *Geranium* at the time I mention, although the latter received no assistance whatever beyond, perhaps, the very simple process of picking off a few dead flower-stems. Some will also be saying that I may perhaps not possess the good varieties of *Scarlet Verbena*. This, possibly, may be so; for I have not yet met with one that meets the requirements I expect of it, although such kinds as *Robinson's Defiance*, *Mrs. Woodroffe*, *Vulcan Superb*, *King of Scarlets*, *Miss Trotter*, and other kinds that way, have passed through my hands. I may doubtless be called fastidious, and in some other colours am still more so than in *Scarlets*; still there are *Verbenas* that I admire, and I trust similar ones will be forthcoming some day in the *Scarlet* way.

Of all the *Verbenas* I have seen, there are none that come so near my idea of perfection as *Verbena Purple King*. An upright and not a rambling grower, it confines itself without mechanical aid to the spot allotted for it, and whether in a bed or in a line, edging or stripe, requires but very little after-care when once planted and started into growth. The flowers of a good blueish-purple and a small dark eye, not a staring white one, present as

a whole an excellent and useful colour, which we do not possess in anything else. True, it is possible, perhaps, to brighten and improve this colour, which I should be glad to see; but I am satisfied with it until this is done. And as the limb or petal of it is more robust than some, it stands longer than most kinds, and does not so soon burn, bleach, or flag with the sun as some kinds do, especially those of the mulberry, maroon, or crimson class—most of which fade very fast under such a sun as we had last August. I hope some extensive Verbena-growers took note of which kinds comforted themselves best under such an ordeal, and will favour the readers of THE JOURNAL OF HORTICULTURE with the result of their experience. My own, I confess, has suffered some change in that respect, as a plum-coloured variety called *Ariosto*, which I have grown and admired for some years, succumbed sadly to the sun, and presented anything but a lively appearance.

Burning with the sun is not an evil confined to the class of dark-coloured Verbenas. Scarlet is likewise affected that way, though much less so than the maroon; there being something in the colour rendering the latter more susceptible to injury than the former. The paler kinds stand better, and pale blue is perhaps the best of any; but it is pitiable to see the outer edges of flowers like that of Lord Elgin fade or bleach into much the same colour as that of the eye; and all dark-coloured ones that I am acquainted with are liable to this, and I fear it cannot well be avoided. Greater substance of petal may, perhaps, withstand it longer, as the leathery form that florists called into their service in the Pansy enabled that flower to withstand wind and weather better than before, although the constitutional vigour of the plant was thereby impaired. Verbenas, I hope, may be likewise improved in texture of flower, and are more likely to be so if the anxiety to have large pips and trusses be abandoned.

Having already stated that my second favourite Verbena is the old cut-leaved species called *paluchella*, which has been discarded in many places, but which I am glad to own as one of the most useful. I have two varieties of it—one having a darker hue than the other, but both approaching the lavender blue of the original. No variety that I am aware of covers a bed more speedily; and although its trusses are small compared with that of others, it compensates for that by the abundance of them. It looks best when seen at a distance of 50 yards or more, and no Verbena that I am acquainted with presents such a mass of colouring, and of a hue we have not many good examples of. The striped variety *V. Imperatrice Elizabeth* is a useful kind for planting close to a window; but at a very short distance its otherwise beautiful stripes become mixed and confused.

Having in some measure stated my dislikes in Verbenas, I will now endeavour to explain what I want in this extensive family. First of all, I want a good bright scarlet Verbena, with the eye of the same colour as the rest of the flower, habit much the same as *Verbena Purple King*, and a constant bloomer. I do not dislike a small dark eye in a Scarlet, it gives greater depth of colouring, but large white or lemon eyes are objectionable. I also want a good dwarf Scarlet of the *paluchella* habit, the colour as vivid as the brighter Scarlet we now have. This dwarf one and the upright one would suffice in that colour. I also want a clear bright blue—not a dark dull blue or purple neutralised with a white eye, presenting a sort of grey colour, but a clear blue like that of *Salvia patens* or some *Campanula*. A medium spreading habit would do for this; but if an upright one could be had so much the better—*Blue Bonnet* was a sort of example this way, but it wanted improving. I have before stated that I would like to see greater substance thrown into the petals of the maroon-tinted ones, so as to enable them to withstand the sun; habit here may also add improvement, and the other colours might also receive a helping hand in the same way. White Verbenas I have little regard for, as we have such an abundance of variegated plants all in some degree more interesting than the Verbena, that a white one is hardly needed except for variety.

It is needless here to enter into the culture or propagation of this class of plants, since so many papers bearing on this matter have issued from the pens of Messrs. Fish and Beaton. Suffice it to say that the most difficult matter seems to be to save as many plants through the winter as will suffice for a good batch of cuttings in the spring. Some of the varieties being so subject to mildew, the white ones especially being liable to this malady, which is by no means easy to prevent, but I believe is often considerably encouraged by a too close and warm atmosphere,

for the Verbena is much more hardy than is generally supposed, as I have repeatedly kept plants in a healthy state in a cold pit covered only by a single mat over a light, and that only in the coldest weather. The plants being in the ground and not in pots, this method, however, does not furnish so many spring cuttings as when the plants are more portable and can be placed in warmer quarters; but it is a very convenient way to those having no better way of keeping them. As this and other subjects connected therewith probably may be treated of hereafter, I will add no more on that head, but again invite the aid of raisers of new varieties to try what can be done in supplying kinds better adapted to the flower garden than those we now possess, and leave the florist to contemplate his rambling plants with their large trusses wide apart to his heart's content. I would also present him with all the fancy kinds, both clouded, white-eyed, and striped, and let me have a few simple but compact flowers growing on plants of compact habit, with constitution proof, if possible, against mildew in winter, and the flower of substance enough to withstand the hot sun of the dog days, and some half-dozen kinds possessing all these qualities are all I want.

J. ROBSON.

BANKSIAN ROSE INJURED BY THE FROST.

My Banksian Rose, covering the south front of the house, 30 feet high, was greatly damaged by the severe winter of 1860-61, and most of it died off during last summer; parts of it are alive and the main trunk threw out young shoots about 8 feet from the ground. Please tell me how to treat it. Should I now cut out all the dead parts?—B.

About the middle of April prune out all the dead wood, cutting to sound fresh parts. After that, nail in the young wood of last summer at full length; and, if the young shoots seem too crowded in any part, thin them by cutting them clean off. Then, as you do not mind flowers so much this season as the filling-up of where the old parts died, the strongest of the young shoots of last year that are within 6 feet of the bottom may be cut back one-half or one-third their lengths, in order to get sufficient wood to cover the wall; and, having them first in the proper places you will see exactly where young wood is most wanted, and you will cut in accordingly.]

STRIPED BORDERS—BOX EDGING.

In No. 47 there are two subjects treated of—viz., "One-sided Striped Borders," and "Box-edging," on which, with your permission, I would say a few words by way of a practical hint in regard to each subject; and as my plan is both cheap and most effective, I cannot but hope it will prove acceptable to many of your readers.

A portion of the kitchen garden here abuts on the shrubberies and walks, whilst an Oak-wood opens thereon, and a broad walk skirts this latter, the said kitchen garden being on the other side. Now, a few years ago, Colonel Austen erected along all this exposed kitchen-garden boundary, which forms a curve, a very light five-barred iron esplanade, composed of hurdles, 5½ feet long and 5½ feet high, each with an upright bar midway, extending in the aggregate and continuously about 70 yards; and as every one admires the result of the flower-fence and border, I will describe how both are furnished. Opposite to each hurdle subdivision of 2½ feet, there is planted a dwarf *Géant des Batailles* Hybrid Perpetual Rose the whole length of the border, and to each hurdle of 5½ feet long is trained also a Hybrid Perpetual Rose, the *Chénédoie*, whose brilliancy of colour and profuse blooming harmonise well with the Rose ribbon on the border below it, and in June and July the effect is truly glorious. The fence is kept gay till the beginning of November by Sweet Peas and *Tropeolum canariense*—the one sown on the border side of the fence, and the other on the side facing the kitchen garden, the whole of which it thus screens from view with massive gorgeousness. The five-foot-wide border itself is laid out thus:—all along its outer edge, and within a foot of the Box-edging, runs a row of *Polyanthuses* and Sweet Williams, both of the crimson shades, planted alternately a foot apart, and they succeed each other well on this loamy soil, being followed late in the summer by a ribbon of bloom running along the whole border, produced by *Campanulas* at 2 feet apart from end to end thereof, all of one sort—the darkest blue. Now, this is a cheap, and at the same

time a most showy border-and-fence garniture, and I can assure your readers that they may feel confident that I am competent to give an opinion on floral effect, when I tell them that I have lived as under gardener both at the Duke of Somerset's and at Lord Tredegar's. The iron fence itself (flexible), and made by a Chichester ironmonger for £5 in all, is kept bright and black by a coat of patent asphalted tar mixture every two years.

As regards the Box-edging here, I never saw any more effective and even, and I find that my predecessor here Boxed the whole 1600 yards thus:—A neighbour gave Colonel Austen three barrowfuls of old Box over a foot high, the upper 6 inches of this were chopped off, and the head trimmed and pressed into a trench made by a spade all round the garden, kitchen and Dutch flower-parterres alike, in the month of October, just before the rains set in, which being warm and the ground also at that time, favoured its establishment most effectually; indeed, no failure occurred, and now being kept about 3½ inches high and well trimmed, such of your readers as admire this most beautiful of edgings, would envy this one here.—T. VICKARY, *The Pavilion, Aldwick.*

THE MANETTI ROSE STOCK.

THERE is to a certain extent such a want of accuracy in your answers to correspondents, page 445, about this stock, so unusual in your columns, that I feel compelled to notice the subject.

First let us talk about "suckers," of which there are two kinds, not hitherto distinguished by proper names; so we will call them stem-suckers and root-suckers—the former springing from the stem below the bud or graft, the latter from the roots, often at a great distance from the tree. The Dog Rose is liable to both these evil habits; the Manetti Rose, as far as my experience has gone, to the former only, although one would suppose from what you say about never being "free from Manetti suckers as long as you live," the contrary to be the case, and that it suckers like Raspberries. The writer of such words must cultivate a most peculiar soil, for I have seen the Manetti Rose growing in all descriptions of soils, from a blowing seaside sand to a stiff clay for many, many years, and never saw it make root-suckers. I have a plantation of Manetti Roses used for propagation; the "stools" are 3 feet apart row from row, and fifteen years old—not a root-sucker is to be seen. Dog Rose "stools" under similar treatment would long ago have formed an impenetrable thicket of brambles, formed by root-suckers.

Your readers may pick out, or cut out, the buds of the cuttings as advised. They will find it avail but little if they are unwise enough to graft or bud a weak-growing variety on the Manetti stock, for it is not one bud but a cluster of buds (the germs of which nearly surround the bud picked out), which at once start into life, if the sort budded has not rigour enough to pump up the sap, which in summer is so abundant in this stock.

To show you that I speak from experience, I will in a few words tell you what has been my custom for the last twenty years (it must be thirty since I used to mould-up my cuttings, which I found not to be good practice).

My cuttings are made as follows:—A shoot of the current year's growth, and which is often from 6 feet to 7 feet long, is made into cuttings 9 inches in length; the only care taken in cutting them is to have the cut at the bottom as little sloping as possible, and close to a bud. Cuttings are made and planted during the month of November, the earlier in it the better. In planting them one bud only is left out of the soil, so that 8 inches of the cutting are buried. They are planted in rows, and the earth is pressed very firmly to them. The buds in the stem, owing to being thus firmly covered, all die.³ When the cuttings have been a year in the ground—i.e., the November twelvemonth after planting, they are ready to transplant for budding. A few, very few, roots will be found on the stems (for most of them are like the specimens sent—as smooth as your hand), and a tuft of roots at the bottom; these, in transplanting, should be placed 4 inches deep. The following August (budding time) the earth is slightly scraped away, and the bud inserted so as to be within 2 inches or 3 inches of the bottom of the stock.

Under this simple management I find no root-suckers, and after the second year no stem-suckers; but then I only bud varieties that are tolerably free in growth, and mostly Hybrid Perpetuals. I had some pillar Roses of free-growing Hybrid

Perpetuals, which were killed by that fatal Christmas frost of 1861; they were nearly twenty years old, and I never remember to have seen, after the first two or three years, either a stem-sucker or root-sucker. They were budded on Manetti cuttings, prepared exactly as I have above described.

The paragraph in page 445 is so contrary to my experience, that I have been tempted to trespass on the patience of your readers. I feel quite certain there is some mistake, and equally certain that you will insert this, although ~~correction~~.—A NURSERYMAN.

[The answer about the Manetti stock was given by me, and I maintain, from my own experience, that it is perfectly correct, and I hesitate not to say that "A NURSERYMAN" is perfectly wrong, both as to the fact of the case and to the theory by which the fact is supported. Moreover, I pledge myself to prove both points to the full satisfaction of "A NURSERYMAN" himself in any London nursery, or in the garden of the Royal Horticultural Society at Chiswick this spring and next summer. But to make plain work of it, I will disbud any Rose-shoot of last season's growth even if it be 20 feet long, or the leading shoot of any tree or plant in our climate, and I will challenge, after doing it, all the practice and all the science of Europe to get one single cluster of buds to grow from any one of them as "A NURSERYMAN" says they grow on disbudded Manetti stocks.—D. BEATON.]

NEW AND RARE PLANTS.

STANHOPEA OCTALATA (*Eyed Stanhopea*).

Nat. ord., Orchidaceæ. Linn., Gynandria Monandria.—It has also been called *Ceratochilus ocellatus*. Native of Mexico. Flowers lemon-coloured, with lilac spots and yellow eye. They are almost too powerfully fragrant.—(*Botanical Magazine*, t. 5300.)

JOCHROMA GRANDIFLORUM (*Large-flowered Jochroma*).

Nat. ord., Solanaceæ. Linn., Pentandria Monogynia.—This stove plant has also had the specific name *Warzewiczii*, and the generic name *Cleochroma*, with its present specific name. Native of Ecuador and Peru. Flowers large and purple. Blooms in November.—(*Ibid.*, t. 5301.)

LIGULARIA KEMPFERII, AUREO-MACULATA (*Golden-spotted Kempfer's Ligularia*).

The well-known *Farfugium grande* proves to be no other than this plant recorded as a Japan plant ever since the days of Kempfer; but described under many other names, such as *Tussilago japonica*, *Senecio Kempferii*, *Arnica tussilaginea folio*, *Doricum tussilaginea folio*, and *Farfugium Kempferii*. Dr. Lindley first called it *Farfugium grande*. Flowers yellow, blooming in December.—(*Ibid.*, t. 5302.)

ENTOMOLOGICAL SOCIETY'S MEETING.

THE Anniversary Meeting of the Entomological Society was held on the 27th of January, and we have to regret that we should have to record that the usual unanimity which has prevailed at the anniversary meetings of this Society was not maintained on the present occasion, the nomination of Officers, and the alteration in the Council, proposed by the Council at the previous meeting of the Society, having been out-voted, and Mr. Frederick Smith, of the British Museum, having been elected President, and Messrs. Sheppard and Dunning Secretaries for the ensuing year.

J. W. Douglas, Esq., whose period of office, as President (confined to two years by the bye-laws of the Society), had expired, delivered an address on the state of the Society, and on the progress of Entomology, which was ordered to be printed.

The February Meeting was held on the 3rd ult., F. Smith, Esq., the newly-elected President, in the chair. After returning thanks to the Society for his election, the President nominated Messrs. Pascoe, F.L.S., John Lubbock, F.R.S., and Wm. Wilson Saunders, Esq., F.R.S., Treasurer to the Royal Horticultural Society, &c., to act as Vice-Presidents for the ensuing year.

Mr. Stainton made a personal explanation with reference to the result of the election for the President and Officers at the anniversary meeting, which was considered highly satisfactory by the numerous members present; and the President announced that the Council had resolved not to accept the resignation of several of the members which had been forwarded to the Society, trusting that Mr. Stainton's explanation would induce them to

³ I enclose a one-year-old cutting, one out of 300,000. You will see that I "speak by the book."

withdraw their proposed notice of secession from the Society. It is, moreover, understood that the state of the Society's collection will undergo a rigorous investigation, so that no ground may remain for the complaints which have lately been made by various members upon that subject.

Mr. J. Lubbock exhibited a drawing of a very remarkable dipterous larva, which he had found under decaying logs of wood. Professor Westwood, to whom it had been submitted, suggested that although of an unknown form, it appeared nearly related to the genus *Platypeza*.

Mr. Stainton exhibited the pupa of one of the species of the curious genus of little metallic Moths named *Micropteryx*, which had by some authors been regarded as probably belonging to the order Trichoptera. The pupa in question, however, satisfactorily determined the lepidopterous character of the genus.

Mr. Janson exhibited seven species of minute coleopterous insects new to this country.

Captain Russell gave an account of the capture of several species of *Lepidoptera*, of very great rarity in this country, including *Argynnis Lathonia*, *Eulepia cribrum*, and *Callimorpha Hera* (a beautiful kind of Tiger Moth), of which he had captured five specimens on a Bramble bush between Rhuanon and Wrexham, in North Wales, on the 27th of July, 1859. One of these specimens he had presented to the British Collection in the National Museum. He also exhibited a beautiful variety of the common Tortoiseshell Butterfly, resembling that figured by Mr. Humphries, in "British Butterflies," pl. 13, fig. 13, taken in Suffolk. A variety of *Lycæna Phlæos*, with longitudinal pale stripes on the lower wings was also exhibited.

Mr. Rye read the descriptions of a species of Rove Beetle (*Lathrobium geminum*) hitherto unrecorded as British, although long confounded with the common *Lathr. elongatum*.

Mr. Crotch also described a species of *Dermeetes*, *D. Frieschii*, allied to *D. vulpinus*, new to this country, of which he had taken a specimen in the New Forest, under a dead horse.

ORNAMENTAL PLANTS.

DIPTERACANTHUS SPECTABILIS (*Handsome Dipteracanthus*).—*Nat. Ord.*, *Acanthaceæ*. *Linn.*, *Didymia Angiosperma*.—This is the largest-flowered and most showy of the genus, and

is deserving of cultivation by all who have a stove or warm greenhouse. Its flowers are deep purplish-blue, with linear markings of a still deeper hue. It was sent to Messrs. Veitch from the Andes of Peru, by their collector, Mr. W. Lobb.

Mr. Smith, of Kew Gardens, has published the following directions for its cultivation:—

"A soft-wooded plant of herbaceous aspect, growing from 1 foot to 2 feet high. It is a native of the temperate climate of Cuenca, in Peru. It is found to succeed in a temperature intermediate between that of the stove and greenhouse, and grows freely in any kind of light garden soil. Like many of the tropical *Acanthaceæ*, after flowering it soon becomes thin and naked. It propagates freely by cuttings. The young plants should be kept in small pots during winter, and receive very little water. In the spring they require to be shifted into a large pot, where they will soon make rapid progress, and produce a succession of large fine blue flowers."

LIMNANTHES ROSEA (*Rose-coloured Limnanthes*).—*Nat. Ord.*, *Tropæolacæ*. *Linn.*, *Decandria Monogynia*.—A hardy annual plant, with prostrate branches, bearing leaves of variable form,

the parts being all linear; sometimes they are quite simple, sometimes pinnately divided, and at other times cut in a bipinnate manner. The flowers are axillary, growing singly on longish upright stalks, and consist of five obovate petals, of a pale dull rose colour. It is not very showy, and should be grown in a dampish, cool place.—From California: swampy places in the valley of the Sacramento; introduced in 1848, by Mr. Hartweg.

If sown in the autumn it flowers in the May following, and if sown in the spring flowers during the summer of the same year.

A FEW DAYS IN IRELAND.—No. 16.

(Continued from page 460.)

BALRATH.

ON returning to Kells from Lough Crew we took a different route, and crossing a corner of Westmeath, found that it pretty well equalled Meath in the luxuriance of its grass meadows. The numbers of cattle that not only feed but get fat on a certain limited space would thoroughly surprise some of our English and Scotch farmers. We noticed on the drive little of agriculture in the general acceptation of the term; little of arboriculture as developed in woodland scenery, except near the residences of gentlemen; and although we saw much in the state of the fences needing improvement, whether regarded as effectual divisions of fields, or as reserves of timber and fuel, we could not but admire the fine macadamised roads kept up without

in height and 50 feet in diameter of head—a dense, symmetrical mass, with the lower branches resting on the green lawn.

This beautiful grass terrace, level as an unruffled lake, and almost as smooth as a polished slab of marble, is 216 feet in length, and 60 feet in breadth, and 30 feet more from the slopes to the elegant iron fence which surrounds the more ornamental grounds. The walk proceeds on this lower level, and at the south-west corner turns round a fine Copper Beech tree. There was just to us one drawback as we looked upon the rich views from it, and enjoyed the carpet-like tread upon it—the terrace is so elevated as to be not only higher than the sloping park, but considerably above the base of the lower windows in this principal and more private front of the mansion; and this necessitates at present a longish slope of turf from the level of the terrace to the wall of the house. We know that the terrace is as comfortable and dry as possible—a great thing in such a dripping climate; and we saw abundant signs that it forms a favourite game and romp ground for the junior members of the family. Being on the same level as the gravel at the north entrance is also an advantage, because no steps or slopes are needed in passing from one to the other; still, it can hardly be doubted that the raising the terrace so much above the base of the lower windows, whatever the use to which the rooms inside are applied, and whatever the other advantages of the terrace itself, just lessens so much the architectural dignity of the mansion.

We recollect visiting a celebrated place, the mansion of which being in a low position, and the approach rather descending to it, dignity of expression was sought and said to be given to it by raising the ground sufficiently in front so as to make the entrance-hall on the first floor instead of the ground floor as before. Perhaps we expected too much, or were too ignorant sufficiently to admire the much-lauded performance which seemed a somewhat bungling affair at best; not that we did not like the raising of the entrance. What seemed to us unfinished was, that the raising was confined chiefly to the centre, and the ground sloping on each side from it. The windows on the lower floor were not only seen from a distance, but some of these from the sloping ground were cut by the ground level into triangular instead of square shapes, so as to give to the whole a make-shift unfinished appearance. Either the ground should have been raised along the whole front, or a balustrade should have been raised sufficiently high to conceal the windows and the area in front of them; or, if part of these were shown at all, something like a level architectural line ought to have been observable. Now, there is nothing of this diagonal cross-cutting of windows to be seen from the level terrace at Dalrath; but we could not help wishing either that the terrace had been lower, or that instead of the deep slope of turf now seen to the wall, an ornamental balustrade should have been built there to conceal these slopes altogether; or, in other words to conceal from the terrace an open area there. A similar-styled but low balustrade round the terrace would give a uniqueness and high-finish to the whole, and then this beautiful terrace might remain lawn as it is, or be turned into a paddled artistic flower garden.

The position of the present flower garden, north of the mansion (see section), full of overflowing with lacer beauty, is another of the striking singularities of Dalrath. If flower garden there is to be near the house, we would, perhaps with preconceived notions and prejudices, wish to see the positions reversed in order to secure grandeur of effect. Many things, however, ought to be considered before that fine grass terrace is broken up into a flower garden. It is almost a relief to find a place now not surrounded with flowers. The principal rooms are, we presume, on that side of the mansion, and at present will have all the advantages of privacy and repose. The rich woodland scenery may also be more thoroughly enjoyed from there being nothing more gaudy near at hand to arrest and divert concentrated attention. Leaving summer out of view, hardly any possible arrangement of flower-beds in winter could be more pleasing to the eye when seen continuously day after day, than a green level lawn in the foreground. Any flower-beds should be sunk in panels so as not to interfere with the more distant scenery. The feeling of privacy will be best secured by a lawn, as the necessary work may be all done in a morning. These are not the days for solitary hermitings, still the very increase of the bustle and activities of life render it alike pleasing and desirable, that opportunities be given for retiring from communings with man, and amid the soothing and hallowing influences of the beauties of nature, to hold unrestrained questionings as to the feelings and desires of our hearts, the conduct of our everyday life, and how

these affect our thankfulness and submission to Him who gives to providence its laws, and to nature its rules as well as its splendours.

The width of the gravel, 50 feet by 120 feet, at the north entrance, gives the impression of ease and roominess. It is on the same level as the grass terrace, and, notwithstanding the recent rains, was firm, dry, and level. It is bounded on the north by the flower garden, but separated from it by a handsome wall some 4 feet in height, and an upright iron pallisade on the top of it, altogether more than 8 feet in height. This wall is 196 feet in length, and is covered from end to end with a dense clothing of the *Cotoneaster microphylla*, pretty at all times, but chiefly beautiful in winter when studded with its red Holly-like berries. The flower garden is 120 feet deep from south to north, in front of the width of the fence, and 260 feet at back. The kitchen garden lies north of the flower garden, and is a square within walls of 100 yards to the side, with half as much more of a slip on the east side, and is well cropped and managed.

Eastward of these is what is called the grove—apparently an old wood some 500 yards in length, and 160 yards in breadth, from which all the trees except the finest specimens have been removed, and the ground cleared and enriched and turned into an American garden. This is surrounded and also divided into four parts by massive hedges of the common Laurel, ranging from 10 feet to 14 feet or more in height. The first division is devoted to scarlet *Rhododendrons* well stored with flower-buds, many of them are 9 feet in height, and from 10 yards to 15 yards in circumference at the base. Here is a magnificent plant of the common *Rhododendron* that threatens some days to monopolise the division to itself. It was, on the 16th September, 13 feet in height, 56 yards in circumference, at the base sweeping the ground, and so compact and full of flower-buds, that in all that space there was scarcely an opening to let the hand in. The subdued shade of the Laurels and a few larger trees seemed to suit these plants well. The second division was devoted to *Kalmias*; the third to *Azaleas*; and the fourth to different coloured *Rhododendrons*, *Andromedas*, &c., in beds.

The north side of this grove is bounded by the *Rhododendron*-walk more than 100 yards in length, and which communicates with the kitchen and flower garden on the west side. The *Rhododendrons* are not the sole features here. A lofty Laurel-hedge, not stiff and formal, but with a sweeping, graceful outline, bounds the walk on the south side, leaving a wideish, irregular verge of lawn between it and the walk. On this verge, at something like regular distances, stands a row of fine old Thorn trees; and these, either from training or from the free access to light on the north side, bend and droop over the walk something like a regular archway. The north side is ornamented with a dense mass of *Rhododendrons*, and a sunk fence separates them from a rich paddock in which favourite stock is reared. This is bounded by the road between Nava and Oldcastle. That walk must be picture in early summer. We may here mention that south-west of the mansion the plantation between it and the deer park is being thinned out for introducing more masses of *Rhododendrons*, which, as they thrive so, may well be favourites.

On entering the Kitchen garden, among other objects of interest is an ancient Peach tree, which has a house for itself 32 feet long, 12 feet high, and 7½ feet wide. The age of the tree is uncertain, but it has filled that house and produced unusually heavy crops for more than forty years. Mr. Ramsay assured us that to his own knowledge it had been heavily cropped for ten years, and yet produced fruit from 6 ounces to 9 ounces in weight. It is the Royal George kind. On measuring we found the girth of stem fully 3 feet. We were sorry to see signs of giving way on one side.

Lower down southward is placed the middle range of houses, 108 feet in length, 10 feet wide, and 10½ feet high inside. This is divided into three divisions. The centre used to be a conservatory, with a Peach-house on one side, and viney on the other. The centre is now also turned into a viney, but has a fine old white *Camelia* in it, with rich shining foliage, height of head 6 feet, diameter of head 8 feet, full of strong, healthy flower-buds. The Peach trees had beautiful wood, and the Vines, if anything, too heavy a crop; but we can say little on that subject, being a very frequent transgressor. Both Peach trees and Vines in these houses are very old, not even the "oldest inhabitant" can tell anything of their age. Will nobody tell us the secret, not so much as to their age, but as to how to get the trees, Peach trees especially, to live so long, and thus continue healthy, seemingly, for ages?

The kitchen garden is divided from the flower garden by a beautiful hedge of Cotoneaster microphylla, about 5 feet in height and 130 feet in length, which has a very striking effect, and by one house more 52 feet in length, 13 feet in width, and 10 feet in height, and which is noteworthy as the oldest viney in Ireland. The exact date of its erection is lost amid the mists of the past. The house has been recently thoroughly repaired, and fresh vines planted, which are doing well. Besides frames, the only other glass structures we noticed were the brick pits 50 feet by 8 feet, used chiefly for bedding and other plants in winter, and Melons and Cucumbers in summer. We also noticed what was not less useful—a new soft-water tank, 33 feet by 10 feet, and 8 feet in depth.

Further than the allusion already made to the rich masses of bloom, we must not linger on the flower garden placed in this somewhat singular position. It struck us that few ornamental grounds would be more improved by the introduction of some of the more spiral of the Pine tribe. Perhaps we failed to see them, or as yet they may be so small as not to arrest attention, but certainly we did not perceive that charm of variety which they always produce among flat, lumpy-headed trees and shrubs. Variety is ever delightful. We could live but poorly on poetry and song, but both do much to enliven the prose of existence.

It struck us that among the labourers and workmen there was the appearance of a cheerful, active, well-to-doism, creditable to their own thrift and self-denial, and indirectly showing how much the landlord and his family are interested in encouraging whatever will increase the comfort and happiness of their humbler neighbours. Facts bearing on social economies may be mentioned at some future time, without specifying directly persons or places. Wretchedness and misery exist but too truly, and that in all lands, and quite as much in Britain as in Ireland. But for infringing the above rule, and so far breaking confidence, we might have shown that these workmen at Balrath, and many more or less like them, paying their three-halfpence per working day for a comfortable home and a large garden (no rent being charged for Sundays and holidays), possessing a cow and their young stock, so as to be able to sell a two-year or three-year-old beast yearly, paying £3 10s. for grass for cow, and in proportion for younger cattle, and hiring land for hay and other purposes from farmers at a price which we hardly could expect to be credited if we mentioned it, and making all subservient to their comfort, and the stepping-stones to still greater improvement; and then it might be apparent that there were growing and general exceptions to that wretchedness which some still delight to gloat over, just because they will see nothing but darkness in sunshine, and can perceive no means for raising themselves into notoriety but by croaking and prophesying about misery, and invoking others to lessen the wretchedness which they themselves will do nothing to alleviate. Talk, talk—words, words—are empty froth. We want the benevolence that speaks in deeds, and, though never insensible to the wail of woe, is less anxious to assist providence than to encourage self-reliance and manly independence. But we must finish by saying that the few hours we spent at Balrath will be sunny spots in memory's recollections.

R. FISH.

MISTLETOE CULTURE.

THE Mistletoe may be grown in any climate upon the Apple and Crab stock, if rightly sown. The seed should be squeezed fresh out of its capsule and applied to the smoothest, healthiest part of the bark. No incision should be made near it, nor should it be secured otherwise than by its own natural gluten, which hardens and fixes the seed in a day or two. It is about a year before it shows its two first leaves. Many seeds are rubbed off by accident, and many more are taken by the birds; but if plenty of seeds are sown in the manner I describe, I feel sure your correspondent of February 18th, will in a few years have plenty of Mistletoe. It grows well on Poplar and Hawthorn, but on the Oak it is very shy, as it wants a soft wood as well as bark, as the roots penetrate into the very heart of the tree, and often the tree on which it lives is killed by the roots passing through the pith. I have seen twice a large Apple tree killed by one root of Mistletoe, which in each tree was sown on the main stem, and I should always sow on the branches on this account. I speak from experience, having grown the Mistletoe in moist and dry climates.—HENRY WILLIAMS, *Croxtan Vicarage, Thetford.*

THE CALIFORNIA CONIFERS.

No other State of the Federal Republic can boast of such magnificent and grand specimens of trees of the order Conifera, or Pine family, comprising Pine, Cypress, Yew and Cedar trees, as California. The twisted Pine, *Pinus contorta*, a specific name suggested by the appearance of the trees, is of moderate size, conical figure, branches numerous and small, leaves in twos, short and of yellowish-green colour; cones of about an inch in length. The tree grows to the height of about 60 feet, with a trunk about a foot in diameter 3 feet from the ground. It is found scattered and dwarfed to the altitude of 6000 feet; it resembles the Jersey Scrub Pine, *P. inops*, common on the barren and sterile hills from New Jersey to Kentucky.

The western Yellow Pine, *P. ponderosa*, is the most common of the Pine family in both California and Oregon, and in some localities it is the only species of the Pine found. Its range is from New Mexico to beyond the Columbia River northward, and from the Pacific to the Rocky Mountains eastward. It is a noble tree, though never rivaling the gigantic Sugar Pine; it is often found 6 feet or 7 feet in diameter 3 feet from the ground. Near the base of Mount Jefferson, in Oregon, one was measured 3 feet above the ground, that showed a circumference of 25 feet. The leaves are in threes and from 4 inches to 10 inches in length, and radiating in all directions, giving the branches of trees a tufted appearance; colour a yellow green. The cones are from 3 inches to 6 inches in length and of ovoid form. The seeds are about the size of Apple seeds. The bark of the trunk is a yellowish-brown: the wood is resinous and brittle.

Sabine's Pine, also called Nut Pine, or Withe Pine, *P. Sabiana*, is not an important tree in a timber point of view. It is disseminated over California; but nowhere forms forests of its own species. The tree is not of conical form like most of the Conifers, but is divided into spreading branches, and resembles somewhat the Oak in form. The leaves are a pale bluish-green: cones solitary and of ovoid form, as large as a man's head, and are covered with spurs. The seeds are the size of large Beans and quite palatable, and find a place among the delicacies of the table. The Indians depend largely upon the cones of this species of Pine for the means of food, after their more desirable aliment, the grasshoppers, have disappeared. It is recommended as an ornamental tree, and as being worthy of cultivation.

The Sugar Pine, *P. Lambertiana*, is a magnificent tree, and is disseminated between the Pacific and the Rocky Mountains, and from the Mexican line to near the Columbus River; it is found mingled with other species, but nowhere forming a forest of itself. It is closely allied to the White Pine, *P. strobus*, of New England, though greatly superior in its symmetry and perfection of form, as in size and vigour of growth. They grow to the height of more than 300 feet, and are found, though rarely, of more than 20 feet in diameter. 200 feet in height and 10 feet in diameter are common dimensions of this magnificent species of the Pine family. Its foliage is light, and the branches are sparsely set, resembling the festoons of Ivy which wreath the columns of the ancient ruins of the old world. Its leaves are in fives, and are almost 3 inches in length, and of a dark blue green colour; a forest of such trees would constitute the lumberman's paradise. The resinous exudation is transparent and white, like that of the common White Pine. It is sweet, and hence the reason for the name, which is common throughout the Pacific region. It is, however, said to be used more frequently as a cathartic than as a condiment.

The American Cembra Pine, *P. cembra*, grows to the height of 50 feet, with a diameter of 2½ feet; the bark of the trunk is white, rough, and thin, resembling somewhat that of the White Oak, *Quercus alba*. The wood is flexible and tough, the leaves in fives and of a bluish-green. The cones are small and not easily found. It abounds only at the extreme limits of vegetation, at an altitude of 6500 feet and upwards.

The western Balsam Fir, *Picea grandis*, is found in the Sierra Nevada of California, near the southern line of the State, and as far north as British America. It is more spreading than most Firs, less conical and broader near the tops. The trunk is straight and smooth in dense forests, and furnishes lumber of good quality. It is called the White Fir on the Columbia and Willamette, to distinguish it from the Red Fir, *Abies Douglasii*. The lumber exported from Oregon is derived largely from these two species of the Pine family. The former species grows to the height of 200 feet.

The White Fir, *Picea nobilis*, is a large tree; branches short, rigid; leaves in rows, short, curved upward, rigid, and of a pale green colour. It is not deemed valuable for lumber. It has been introduced into England. The western Silver Fir, *P. amabilis*, is found in the Cascade Mountains. The wood is white, and is inferior for timber. It is an inhabitant of the almost inaccessible mountain regions. The tree in form is a dense, slender spike of dark green foliage, is of great arboreal beauty, and is cultivated in England as an ornamental tree.

Williamson's Spruce, *Abies Williamsonii*, is a tree of large size and of alpine habits; foliage resembling that of the Larch, leaves pendent, $1\frac{1}{2}$ inch in length. It is the finest Fir of the genus, and extends to the line of perpetual snow. It grows to the height of 100 feet. Douglas's Spruce, *A. Douglasii*, is large, and one of the best-known trees of the Pine family on the Pacific coast. It formerly attracted the attention of the exploring botanist, and was sent to England, where it has been cultivated. The cones are pendent. It is one of the giants of the forest: it attains the height of 300 feet and more. It forms forests of the most extraordinary density. Its foliage is confined to a tuft at the top, its trunk being as straight as an arrow. The lumber per acre of the Douglas's Spruce is said to far exceed that of any other equal area on the globe. In the Willamette valley a Spruce of this species, 6 feet in diameter at the stump, measured 216 feet where the top had been burned off, and was 15 inches in diameter at the extremity. The wood, as is true of most of the Spruces, is harder to work than Pine, but is excellent timber for planking, joist, &c. The Douglas Spruce covers the western slopes of the Cascade Mountains, and the banks of the Columbia River. It extends northward on the Sierra Nevada, and to the line of Mexico.

Menzies' Spruce, *Abies Menziesii*, has been introduced into Europe, where it is cultivated. It is not so large as *A. Douglasii*, but is a symmetrical and beautiful tree. Its foliage is rigid, and pricks when brought into contact with the skin like needles.

The great Arbor Vitæ, *Thuja gigantea*, is said to be the finest species of the genus known to the botanists. Its foliage is beautiful. It is abundant in Oregon. In size it is scarcely inferior to the Sugar Pine or Douglas's Spruce.

The Redwood, *Sequoia sempervirens*, is only second in size, and is called the first in importance of all the trees in California, though not far surpassing the Sugar Pine. It is said to nearly equal the *Sequoia gigantea*, designated the "Mammoth Tree." Professor Lindley, of England, considered the latter as forming a new genus, and called it "*Wellingtonia gigantea*." It makes excellent timber. Its foliage, as common among its congeners, is dimorphous on young trees—i.e., assuming two crystalline forms, leaves long, resembling those of the Cypress and Yew trees. Its cones are elliptical, and 2½ inches in length. Its timber is valuable. It splits well, and may be converted into plank without a saw. Resinous like the Cedar, it is, therefore, very durable when exposed to the weather. It is regarded as one of the most extraordinary trees of the Pacific coast.*

The Western Juniper, *Juniperus occidentalis*, closely resembles the *J. virginiana* of the Atlantic States, differing from it by bearing larger berries, producing more glandular and resinous leaves, being also less acute; the wood differs by being white, thus not resembling the fragrant wood of the Red Cedar. Its diameter is 3 feet near the ground, and is 40 feet in height. Its fruit is sought by some species of birds.

The Western Larch, *Lasix occidentalis*, is large, tall and slender, branches short and small, leaves long and delicate, cones ovoid, 1½ inch long. It is unlike the Haematack of the Atlantic States in its general appearance. It grows along the streams, and also rises to the height of 150 feet, with a diameter of 3 feet; foliage light and feathery, and a pale bluish-green.

The Western Yew, *Taxus brevifolia*, differs essentially from the Atlantic species in its arboreal habits, frequently growing to the height of 75 feet; foliage thin and a yellow green. It differs also from the arboreous Yew of Europe. It is found on the Sierra Nevada, down to the southern part of California.

* The *San José Tribune* says that Colonel Howard, who has recently visited the locality of the "big trees," has furnished that paper with the accurate measurement of some of these vegetable monsters, which with their respective names are as follows:—

Heracles, 27 feet 10 inches diameter; Pioneer's Cabin, 27 feet; Pride of California, 25 feet 3 inches; Mother of Forest, 20 feet 8 inches; Guardian, 20 feet; Miner's Cabin, 19 feet 5 inches; Big Tree, 8 feet from the ground, 21 feet 8 inches; 30 feet from the ground, 14 feet 5 inches.*

These measurements were fairly made, a sufficient distance above the ground to truly indicate their size, and may be relied upon as correct.

The California Nutmeg tree, *Torreya californica*, is a rare tree in California, growing to the height of 75 feet, and resembling the Yew. Its fruit is used as a condiment. It is a graceful tree and will be introduced into cultivation.

The Naotka Cypress, *Cypripinus nutkotensis*, is a tree of moderate size, branches sub-erect. It is found in the Cascade Mountains, and resembles the *Thuja occidentalis*; the trunk is gradual and twisted, and set with dead limbs; foliage sparse and rugged, and presents an uncomely appearance. Its habitat is near the snow line.

The California White Cedar, *Libocedrus decurrens*, is common over California and South Oregon. It rivals the Sugar Pine in diameter though not its equal in height. It attains the diameter of 7 feet. It resembles the *Thuja occidentalis* about Lake Superior. It seems to be affected by a kind of dry rot, whereby its trunk has a honeycomb-like appearance, rendering it valueless for timber. Its fruit is pendulous.

In preparing this sketch of the Pine family of the Pacific coast, we have been indebted to Dr. Newberry's botanical report, a part of the Pacific railway survey. All who have read of the mammoth trees of California have become interested in the wonderful Pines of the auriferous State. The grove of mammoth trees is situated on the ridge between the San Antonio branch of the Calaveras river, and the north fork of the Stanislaus river, lat. 38° north, and long. 120° west, at an elevation of 4370 feet above the level of the sea, and ninety-seven miles from Sacramento city. Some of our readers may recollect of having read accounts of a cotton party of thirty-two persons, engaged in dancing four sets of cotillions at one time on the stump of the "mammoth tree," *Sequoia gigantea*, besides musicians and lookers-on. The stump, 5½ feet from the ground, measured more than 28 feet across it. Five men were employed twenty-two days in felling the tree with pump-augers. When cut off, so erect was the trunk that it stood upon the stump; and about two and a half days were spent in driving wedges until the monarch of the forest fell. It is supposed to have stood nearly 3000 years. The "Mother of the Forest," as it is called, had its bark removed to the height of 116 feet, and now measures 81 feet at the base; 20 feet from the base it measured 69 feet; 70 feet from the base, 43 feet and 6 inches; and 116 feet upward, 39 feet and 6 inches. Its height was 321 feet; and the tree is estimated to contain 537,000 feet of inch lumber.

The "Father of the Forest" lies partially buried in the soil, and was the largest tree of the group. In circumference at the roots, this tree measured 110 feet, and 200 feet at the branches. It is estimated to have been 435 feet in height; 300 feet from the roots, and where it was broken off in falling, it is 18 feet in diameter. Near by are the "Husband and Wife" leaning against each other. "Hercules" another giant, is 320 feet high, with "I. M. Wooster, June, 1850," cut upon the trunk, showing that he had the precedence over Mr. Dowd in the discovery of the famed "mammoth grove." The "Hermit," a lonely old fellow, is 318 in height, and 60 feet in circumference. The "Old Maid," a stooping forlorn-looking spinster, of the big tree family, is 261 feet in height, and 59 feet in circumference. The "Old Bachelor," a lonely and solitary specimen, exceeds the "Old Maid" in size, being 298 feet in height, and 60 feet in circumference. Besides these there are the "Pioneer's Cabin," the "Siamese Twins," the "Guardian," the "Mother and Son," "Horseback Ride," "Uncle Tom's Cabin," the "Pride of the Forest," the "Two Guardsmen," the "Three Sisters," or as called by some, the "Three Graces," the most beautiful group in the grove. Could this wonderful historical group turn historians, they would a marvellous tale reveal, far more interesting than the delightful one of Mr. Tirrell, the artist, from which we have drawn the foregoing statements of the dimensions of the mammoth grove of California, which so far exceed that of any other of the explored regions of the globe.—(*Boston Cultivator*.)

WORK FOR THE WEEK.

KITCHEN GARDEN.

THE recent dry frosts and cutting winds, though unfavourable to vegetation, have afforded a very seasonable opportunity for forking over ridges, wheeling on manure, and trenching-up vacant pieces of ground. As the soil is now in fine condition, the committal seed to the earth should be vigorously followed up on all suitable occasions. *Artichokes*, make new plantations, and fill up old ones. *Broad Beans*, the advancing crops to

have more earth drawn up to them. *Brussels Sprouts*, make a small sowing, as also of *Borecole* and *Green Savoy*. Attend to the pricking-out *Canilliflowers*, *Cabbages*, and *Lettuces*, as they are likely to be very much in request by-and-by. *Carrots*, the main crops may now be sown where the ground has been trenched and the surface soil is in a mellow state. Keep up successional sowings of *Lettuces*, *Radishes*, *Spinach*, and small salading. *Mushrooms*, keep up the heat of the house, if the beds are in full bearing, to about 60°; retain a moist atmosphere by watering the paths and flues. *Onions*, sow the main crops, as also *Farnsips* and *Leeks*. *Peas*, the advanced crops to have more earth drawn up to them, and some branches of spruce fir or other such sheltering material stuck in on the windward side of the rows. *Potatoes*, attend to the planting while the ground is in such a fit state for so doing. *Rhubarb*, make fresh plantations, as also of *Sea-kale*. *Turnips*, sow the Early Dutch in a warm situation.

FLOWER GARDEN.

Get soil and pots in readiness for potting *Carnations*, for which mix up three parts good turfy loam, two parts well-rotted cowdung, and one part rough sand and charcoal together, and remove it into the potting-shed. Lawns, or portions of them, that are apt to burn in summer, would be benefited by a top-dressing of some good strong soil in a well-pulverised state. The pruning and top-dressing of *Roses* will require attention. Plant *Lily of the Valley*. Plant out *Pansies*, *Carnations*, *Wall-flowers*, *Sweet Williams*, *Canterbury Bells*, *Daisies*, *Pinks*, *Scarlet Lychnis*, *Columbines*, &c. Sow *Wind Anemone* for autumn blooming, and attend carefully to the sowing of showy annuals and perennials. Do not forget *Mignonette* and *Sweet Peas*. Look over all recently-planted trees and shrubs, for the purpose of ascertaining whether they are securely tied and staked; for if such operations are neglected, and they are blown about by the boisterous winds of this month, they will suffer irreparable damage at the roots. Proceed with all operations that involve the necessity of wheeling or removing earth. Roll and sweep lawns; clean, or turn gravel walks where necessary. To eradicate weeds there is nothing like hard labour. Fork over flower-beds, to get the soil in good condition for the reception of the bedding-out plants. On the first dry day the *Tulip*-beds should be carefully gone over, breaking the surface soil with the hand, so that all interstices may be filled up.

STOVE.

Continue to increase heat and humidity, making use of the engine or syringe pretty freely. Stop in time all rank and unruly-growing shoots. Clear away dead leaves and faded blossoms. Water with care, and give air at all favourable opportunities. Make cuttings of the various sorts of *Begonias* for blooming in November and December. The *Amaryllids* in flower will require a rather liberal supply of water; but great care to be taken not to overdo it. Growing *Orchids* will require shading for a couple of hours during bright sunshine.

GREENHOUSE AND CONSERVATORY.

Any *Camellias* that have bloomed in the conservatory, if misshapen or getting too large, may now be cut-in; and, if afterwards placed in a sweet, growing, moist temperature of from 50° to 65°, they will soon break fresh and make fine plants; syringe them daily once or twice, and, if necessary, give a little manure water. The same treatment may be adopted with the *Chinese Azaleas*; and, if the shoots are stopped twice or thrice during their growing season, fine bushy plants will be produced. Heaths may now be shifted; use plenty of drainage and sandy heath soil full of fibres, the ball to be thoroughly moist before shifting. *Pot Cape* and other bulbs as soon as the foliage is getting strong; use chiefly loam, leaf-mould and fine sand. The *Cinerarias*, herbaceous *Calceolarias*, *Pelargoniums*, *Fuchsias*, &c., to be shifted forward as soon as they fill their pots with roots. Proceed as diligently as possible with the repotting of such of the hard-wooded plants as require it, so as to give them time to make a vigorous growth. Be careful, however, before potting to put the ball in a moist state, and avoid giving large shifts to weak growers.

PITS AND FRAMES.

Maintain a kindly heat in the cutting-frame, top the cuttings that have taken root and are beginning to grow; but if more are wanted they may be allowed to grow until they are of sufficient length to furnish a fresh batch of cuttings. Continue to put in cuttings as previously directed. The *Calceolarias* for bedding-out purposes, if well established, may soon be planted

out in a turf-pit in some good sandy soil, where they can be protected from frosts and cold cutting winds. Let the air in favourable weather circulate freely among the *Auriculas*, *Carnations*, &c., in frames.

W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

TURNED over ground roughly to get the benefit of the frosty nights. Put more *Sea-kale* and *Rhubarb* into *Mushroom*-house. Will bring the next forward out of doors by covering with pots and boxes, or hand-lights. Earthed-down the last made-up *Mushroom*-bed, using, as we generally do, stiffish fresh loam for the purpose, digging down to the understratum of the kitchen garden, if other material cannot be got, placing it on from 1½ inch to 2 inches thick, kneading and beating it firmly, making it as smooth as possible, and then watering all over; after which, by heating with a clean spade, and drawing it along at the same time, a fine smooth surface is left. We have frequently used turves reversed for the purpose, and some finer soil to fill up all cracks and cover the surface: this plan always answered well if the mere grass was first pared off and set aside for other purposes, and care was taken to know that no spawn of other fungi was in the turf. Before spawning we like the bed to be about 85°; and, if after a few days it does not get any warmer, we earth-up as above. We frequently make bits of beds, because, though I am not so particular about the materials as some writers in the *Journal*, I am generally so short of it that I can only make small pieces at a time; but these generally yield us an every-day supply. A heap is now preparing for another small bed, two parts of which may be horse-droppings, one part long dry litter cut to three-inch lengths, with a handbill over a block, and one part dry fibry sods: such a mixture makes a rare bed, and, well managed, may be expected to yield a white sheet of *Mushrooms*. Put in a light of *Asparagus*, which must be the last forced this season. And planted another frame of *Potatoes*, sowing *Radishes*, *Lettuces*, and *Canilliflowers* between the rows.

FRUIT GARDEN.

Looked to *Strawberries* as last week, noticed some fly appearing on them in the *Peach*-house, still in bloom. Was unwilling, therefore, to smoke with tobacco if possible. Applied the thumb and fingers, and with a small spring-hair brush, rather more virily than a camel-hair brush, scattered a little powder of white hellebore over the trusses and where a fat gentleman had escaped the thumb on a leaf-stalk, and the remedy seems to have been pretty effectual. Noticed a twig or two of the *Peach* trees with several fly on them, and scerred them the same. An ounce would do ever so much thus tenderly used. I have an objection to smoking much until the blossom begins to fall, some buds fell before opening from getting too dry last autumn. When we gather the fruit we are sometimes not so thoughtful of the trees as we should be, though it is always bad policy then to forget them. Others, however, we had to thin a good deal. When *Noblesse*, &c., come extra thick, it is always best to thin them pretty severely. There is then more certainty of setting well than if blossoms are left so thick; and it is just as easy thinning-out the bloom-buds when far enough advanced, to make sure that the flowers left have male and female organs, especially the latter, all perfect, as it is to thin out the fruit afterwards. Watered the soil, to keep up a healthy growth, but disapprove of anything like saturating when the trees are in such a condition. Examined trees in glass-covered case, and gave several water, being afraid they were rather too dry to sustain the swelling buds. Will give a little to more in a week or so, but will devise some means by which that watering will give warmth to the soil instead of taking it away by evaporation afterwards. No better weather could be for such cold fruit-houses, which have been kept with all the air possible on night and day, except in one tempestuous windy night, so as to keep the blossom as backward as possible, so as not to be injured with frost afterwards. With a glass covering the air-giving and air-regulating will pretty well determine the fruit-ripening time afterwards. Our *Peach*-buds in such a position have yet no signs of opening, though swelling. I do not envy some friends who say that theirs in similar circumstances are in full bloom. Despite of windmills and daubing the buds of dwarf *Pear* trees we have been obliged to use the gun among the tits and bullys, and we fear that in this or next year we must resort to netting. It is such annoyances to have nice trees well supplied with fruit-buds,

and to find that as they swell the heart is nipped out of them. Pruned and nailed Apricots, the buds now swelling, though the wood has that hard appearance that says the trees have not quite recovered from the severe biting frost of last winter. As an evidence of the coldness and exposure of this place, I may mention that Apricot bloom is often open in the neighbourhood a fortnight before ours are pleased to do so.

PLANTS.

Amongst flowering plants watered with care, ringing the pots to see how they are for moisture before wading the water-can. Find a little fly coming on the Cineraria in the conservatory, will take them out and syringe well with lime, lye, and soft water, clear, and then with clean water, and place in house to avoid smoking if possible. The pots were not set on moss this season, and hence, I presume, the fly. The Cineraria dearly likes a cool, moist bottom to stand on, and with plenty of air will scarcely ever then show a trace of the fly. Shifted large-Fuchsias that had been pruned and put into heat as previously described, shaking most of the soil from the roots, and replacing with fibry loam and a portion of rotten leaf mould and old Mushroom dung. If the roots were dry they were soaked in a tub before potting. Most plants had then a little water given near the collar or stem, and the tops were syringed, and repeatedly in sunny days, to prevent the young short shoots flagging. Water at the root is sparingly given until the roots work into the fresh soil. Reputed Begonias, sowing the old ones much in the same way, and giving more room to young ones. Potted Geraniums and other bedding plants to be afterwards turned into temporary beds. Propagated Dahlias, and made preparations for sowing *Lobelia speciosa*, and lots of other things next week, &c.—R. F.

TO CORRESPONDENTS.

* * * We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to The Editors of the "Journal of Horticulture, &c.," 162, Fleet Street, London, E.C.

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

We cannot reply privately to any communication unless under very special circumstances.

ADDRESS R. F. — His address is Mr. Watts, Old Kent Road, S.E.

EDUCANDA MOUTBATA ALBA (*A. Subseriata*). — It cannot be an old plant yet, therefore it is not desirable to give it the least forcing, this spring, and the "outs" are now on the move, therefore it would be a good plan to shake them out of the dry balls, and to put them into small pots. This seed does not seem so free in rooting and filling pots as the old Atholpi.

HYDRIC FERN (*Idem*). — There is not such a thing as a Hybrid Fern, so far as we know.

SPIRÆA VESUSTA NOT FLOWERING (*Idem*). — If your plant is that which is of the same section of the family as *filiflora*, or *flora* in the Meadow, with tall spikes of purple flowers, it requires the same deep, light, rich, friable soil as the best new *Flotoxas*, a good open situation, and not to be disturbed other than once in five or six years. It is a very good herbaceous plant; but there are several *Spiræa vesustas* among popular names down in the country.

WET CORNER OF A PLAT-BED (*Idem*). — One corner of a peat-bed, in which Heaths and Azines are growing is "unavoidably" very wet. What will grow in the wet corner? Nothing better under the circumstances than the English and the American Cranberry (*Oxycoccus patens* and *O. macrocarpus*). On the edges of the way wet part the two native varieties of *Erica tetralix*, *nuba* and *alba*, will grow better than in the dry parts. We have seen *acris* covered with this little Heath, along with *Rubus*, *Carex*, *Cotton Grass*, *Pinguicula*, *Drosera*, and some others where a sleep could not graze without being bogged—that is to say, without sinking in the bog. The double-flowered *Galium palustre* would also grow there to perfection. *Euphorbia* and *Lythrum* would also do there; but being too high for the rest of this family bed, we would not attempt them.

MELONS (*P. L. E.*). — Any of the popular Melons may be so grown, if the season has plenty of sun. See answer about Melons last week. In case the summer should be cloudy, plan so that you can earth the roots. For ridges, sow in April under protection, pot off and keep in four-inch pots, and see what the plants will do, then transfer to six-inch or seven-inch pots, and keep them out of doors well watered. Some plant out and carefully hit a fortnight or three weeks before sowing, so as to be well established in the pots. Some even take up a few days beforehand, but just as a rule that it is a sham.

PERCIVAL PUMPERN (*A. Subseriata*). — It is an old-fashioned Cape bulb that is worth a keep in a pot, and is grown in a pot, and is a good subject for the front wall of greenhouses, where it will live and bloom with some covering, as with ead ashes or tan, from November to May. But you might first bloom it in a pot, and see how you like it. The same soil as for forcing *H. aurantiaca* will do it, but it will grow in anything, and will do with the same treatment as *Tom. Eschschol*.

SEEDLING CYCLAMENS (*Idem*). — Your best about seedlings of *Cyclamen persicum* is the most difficult thing we ever hear of. They are coming into bloom in the pots they were sown in, and now you want to divide them into single pots, and place them in a Cucumber-frame at 65° of heat! If you want to do this, they would not see six or seven seasons for the next seven years. You may leave them exactly they are till the middle of next September. In the meantime keep them as cool and airy as if they were Cape Heaths. Towards the latter part of May the leaves will be decaying, and in the first week in June turn the balls entire out of the pots, and plant them in a greenhouse in a north one, and let them out at the end of the ball of the bowler to over the tops of the balls. There let them take their chance till September, and when you see the first move for growth up with them, shake the balls, and put the roots into separate small pots; then if you could give them one month of mild bottom heat of 60° to 70°, and not more than 40° to 50° of top heat, you would have the best set of *persicum* in the country.

PROMOTION OF NAMES (*A. Subseriata*). — There is no work giving the pronunciation of plants in the same mode that Walker's dictionary explains the pronunciation of common words.

GAS LIQUOR (*H. F.*). — It is a very powerful application, and we cannot give any general rule for using it as a manure. Buy a pamphlet published out of Oxford, and see the full details. It is the "Liquidum" of the *A. monicalia* of the Gas Works, price 1/6. It contains information about the use of the refuse lime.

GERANIUMS AFTER WINTERING IN CELLARS (*Idem*). — The question about the right time to get out old Geraniums from cellars and other parts, depends entirely on what circumstances one has to grow them properly afterwards. The best way would be to have them up from the middle of February till now, or second week of March; to cut off all their very small roots which are dead, or ought to be; to cut out any dead or damp parts; to pot them in small pots as their roots could be put into without cramming; to then plant them in a pot for a week or two, and then to put them in a pot at the top heat of from 50° to 55°, and a little air on in the middle of mild days; after the roots begin to fill the pots, to renew them to a dry greenhouse for another month. But there is not one in a thousand who can do anything of the kind for want of room; therefore, the best way for them is entirely out of the question in most places, so that every one does them in the next best way he can afford. And some cannot touch them before the middle of April, and then only to put them out of doors without pots in some warm corner, and cover them well from the frost, so that they will be done in many ways, and each way is, we shall say, the best for that place.

CARESSING ROSE (*H. Wood*). — The best time for doing this is during showery weather in June.

PLANTING A FLOWER GARDEN (*A. Constant Subscriber*). — We are sorry we cannot do as you wish. We only point out the errors and improvements in proposed planting submitted to us.

PLANTING VIOLETS IN VIBRIF (*A. Seven-year Subscriber*). — At the warmest soil plant the Muscats, then the *Gas Colman*, *Flemingians*, *Sweetwaters*, and *Muscadines* in the order we have named them.

MANURE FOR AN OLD SUBSERIATA (*ogr*). — Poultry Book for the Many will direct you as to soil management. Figs you may learn how to feed from the book you have. Cows and dairy operations are now being discussed by "The Doctor's Box," and how to cultivate small plots is taught by an "Allotment Gardening for the Many." Any special questions we shall gladly answer these communications.

CROSSING FINEE REPTER (*Sr. Mary's Church, Torquay*). — You will see what Mr. Beaton says to-day. It can be had at Kingston-on-Thames, Bristol, and other places where the Cooper-nut shells are crushed. See an advertisement to-day of a retailer of it. (*Frugiter*) — It is not the right method, nor anything like it.

GRASS PLANT (*T. Lincoln*). — Your planting is good so far as is indicated at the plan. Any one of the methods indicated in our No. 416 would send your beautifully-cultured borders, and, of course, the one you think the best will, therefore, be the best for you to adopt; but No. 2, in fig. 7, is chiefly omitted for such a scale as your garden is on; and No. 2, in fig. 6, will make you a better border.

VARIETY *H. B.* — The blue of the Cooper-nut makes an excellent drainage for the plants we are now mentioning, and is the most totally different from the reddish ones, which is best for growing Ferns, &c. The end of September and the whole of October is the latest period to sow *Spigularis*; but it is best from spring seedlings from a sowing any day in April. The beginning of October is the best time to get in *Conifer trees* in pots from the nurseries, and April is the worst time, as the first severe frost-acted principle has run them down to the worst and weakest parts. Always recollect, October is best for all pot plants from the nursery, and do not forget that November is best to obtain Roses. Which ever *Cypress* is the cheapest, is most certainly the best for putting into flower-beds in winter. A sixpenny *C. p. nana* is not just as well as a shilling one, and a shilling one is not quite the cheapest kind; but the varieties of sempervivens ought to be the cheapest. *Gonioma*, *Lambertiana*, and *macrocarpa* are very nice kinds and very reasonable in price.

HEBEN-ROSE (*Inquirer*). — The Musk Mimulus will not do at all as you intend it; but as it is desired to have the Musk seed we would plant the Musk in a pot, and get it to germinate in the way directed. Any sun, and allow the two full 10 inches in spread, and clip down the Musk; it will get in excess. Then you should put Peas where you intended the Musk, and the Purple one at the back next the wall. The best thing to do with the seeds of all the kinds of Hebeas, which is a common name, is to sow them in a pot, and to give them to the tows, for there is not one out of all them that is worth the value of a straw in this country. We had scores of them through our hands in a Melon house of the very best kind. Even the Spanish and American water Melons are not one-half so good as a slice of raw Turnip or Potatoe. The *Ladan* *Hapharis caudata* is a coarse rubbish not worth sowing.

VARIETIES (*An Old Constant Reader*).—If your burnt earth is free from ashes, and it is in little hard lumps something resembling broken pieces of pots, it will be good for lightening the soil in pots, and act much as rough sand or pebbles would do. If mixed with the dust or very dusty, you had better use it on the ground out of doors. The plant called the "Bear's-foot" is the *Helichrysum* species, but that cannot be what you mean. The Bear's-foot Fern is the *Pavalia canariensis*, but we are not sure if that is the Fern you have. We cannot tell what is the matter with your *Aecia*, it should flower by-and-by on the growth of best season, if the wood was at all well ripened in the autumn. (Give it plenty of water now, and manure water as soon as it shows the flower-lods. The compost will do for *Begonias* admirably if the manure is old and sweet.)

SWEET-SCENTED ANNUALS (*Lee*).—We confess we have not given the subject sufficient attention, and the time you have given is so short, and, then, perfume is so deceiving, that to what some people like others dislike. We have in the market, and that cannot be what you mean. The *Hare's-ear* annuals with perfume. Those to be sown in heat or green-house.—*Datura Wrightii*, *D. meteloides*, *D. coronata*; *Dianthus Helledwegii*, &c.; *Mimulus moschatus*; *Martynia fragrans*; *Nicotiana glauca*; *Petalonia*; *Salpiglossis*; *Schizanthus*; *Verbena* varieties; and some would say *Balsam* of colours. Out of doors.—Sweet *Alyssum*; *Candytuft* of colours; *Catlyps* of colours; *Clarkias ditto*; *Indian Pinks*; *Erysimum Peroffskianum*; *Mignonette*; *Peas*, Sweet, of colours; *Nasturtiums* of kinds; *Piblox Drummondii*, varieties; *Stocks*, Ten-week, &c.; *Virginia Stock*; *Wallflowers*.

PLANT ON THE REINS OF LONDON (*Reactor*).—The plant which came up so abundantly among the ruins of that part of London destroyed by the great fire of 1666 was *Stegobrium Iris*, or *Boal-leaved Hedge Mustard*. It was in such quantities that Morison, who was a contemporary, says it could have been moved. One of its popular names, London Rocket, alludes to the circumstance.

SEEDS IN STRAWBERRY-BED (*Idem*).—Two or three soakings with lime water will give them a quietus.

COCA-SALT FINE REFUSE (*An Old Constant Reader*).—The refuse from the mat and brush-makers is of no use for Fens, &c.; or, rather, it would destroy them if used as a substitute for soil. We have so many applications on the subject that we must make arrangements for the easy supply of the demand. See advertisement.

SCORPION THRIFT (*J. L.*).—We do not know a plant so named. If you send us a specimen of the flowers and leaves we may identify it.

HEATING SEAM-ROOFED GREENHOUSE (*An Amateur of Peabrook*).—Of three-inch piping for hot water you ought to have a flow and return pipe on each side.

SHADING FERRET IN GREENHOUSE (*T. Best*).—The best temporary shade you can adopt is by painting the inside of the glass with a creamy mixture of whitening and size. If a little Prussian blue is ground in with it the colour is agreeably tinted.

PANTRY GLASS (*A. F.*).—It is quite hardy. Only remove the dead leaves, do not cut it down. See-glasses may be obtained of any of the dealers in glass who advertise in our Journal.

NAMES OF PLANTS (*P. M., Ireland*).—It is only *Gymnogramma sulphurea*, perhaps a dwarfier variety than usual, if its present size is not the mere result of the treatment it has received. (*H. Woods*).—1, *Pernettia imbricata*; 2, *Gerardia dipetala*; 3, some *Anacardium* species plot, utterly indeterminate by a leaf. (*H. W. H.*).—It is *Saxifraga ciliata*. It is a native of Mussooree and other parts of the low ranges of hills in Northern Hindostan. (*J. M., Guernsey*).—*Narcissus olerius*.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

POULTRY, &c., SHOWS.

MAY 14th and 15th. TAUNTON and SOMERSET. Sec., Charles Ballance, Esq., Taunton.

MAY 27th, 28th and 29th. DAY and WEST OF ENGLAND (City of Wells). *Steward*, S. Pilsam, Esq., Manor House, Taunton. Entries close May 1. JUNE 4th and 5th. BEVERLY and EAST RIDING. Sec., Mr. Harry Adams.

EGG-HARVEST DEFICIENT.

WHETHER from atmospheric or other causes we cannot tell, but we have many complaints that fowls have not laid well, and that sitters have been scarce. As it is very essential to have early chickens, whether they are intended for table or for exhibition, our readers, like ourselves, will be anxious to get forward. Just as extravagance is mostly justified on the score of economy, so we are never so impressed with the necessity of being beforehand as when the fact of being all behind has rendered it impossible. We have had two chickens instead of forty, and as it is proverbial, "busy as a hen with one chick," so we gave all our energies and attentions to two promising individuals, both of the masculine gender, one a Cochins, one a Spanish. The reflection if we had but pullets to match incited us to exertion. We like March chickens, they are generally hardy, and are, if defective, good eaters and saleable at market. We have, therefore, tried with our hens' eggs that which we have practised for many years with our Pheasants. It would perhaps be more correct if we said we had partially adopted it, and thanks to the thought, we have several hens surrounded by broods of from twelve to fifteen chickens. We put two or more hens on eggs on the same day. When within four days of hatching, we try all the eggs in warm, not hot water; a bowl with 3 inches of water is enough.

The eggs are taken from under the hen, and put in the water; after floating for a few minutes, one and then another will begin to "waggle" or "wobble" in the water, some of them almost violently, and all that will hatch will make a sign of some sort sufficient to indicate vitality. It is seldom at this time of year all the eggs that make up a sitting are good, and, therefore, out of the thirty-three or thirty-nine eggs that have been under three hens, those that give evidence—say twenty-two or twenty-six—are put under two of the three. They bring them all out, and take to them. The third hen, like *Corny Delany's* mother, who was persuaded it was Lent during five years, because they could afford to buy nothing but herrings, is persuaded she has still three weeks to sit, and is supplied with fresh eggs. She lends herself easily to the deception. As these large broods require much warmth during the night, we not only cover them closely, but we put them in an out-house every night.

PRESERVING EGGS.

EGGS preserved according to the following directions are good for puddings, omelets, cakes, or poached eggs even, at the end of the year.

To one peck of fresh lime put three pails of boiling water; stir it well up; let it stand twenty-four hours. If an egg when put in sinks to the bottom it is ready; if the egg floats, the lime is too strong.

Six score eggs put in an earthen pot holding a pail and a half of water and half a peck of lime will supply a family of four to five persons well for the year in puddings, &c. I have ever found the eggs perfectly sweet. I put them up in February, March, and April, as I find I can spare the eggs.

My poultry are Duckwing Game, and Pheasant fowl. The Game eggs are very rich, and afford excellent birds for table; so do the Pheasant fowl.

I feed my February-hatched chickens upon boiled rice, barley-meal, and meat chopped fine. The rest of my poultry have barley (morning feed), scraps from the kitchen, and the rest they find in two paddocks. I never have my birds ill, they never become overfed, and having plenty of room to go about.

I rear pullets early, to lay in winter, and the older ones for summer, so I have eggs nearly every week in the year.—ISABELLE DE ROUBIGNÉ.

HALIFAX POULTRY SHOW.

THE first annual Exhibition of this Society took place in the Riding School, Halifax, on the 1st instant.

Originally, we believe, the Show was only intended to be for single Game cocks and pairs of Game hens. However, a wish having been expressed that it should be extended, two classes for Hamburgs were included, as well as sweepstakes for Game cockerels, and single cocks in Dorkings, Cochins, Spanish, "any other variety," and Game Bantams.

Encouraged in the attempt to establish an exhibition at this time of the year, the one we note having proved successful financially as otherwise, doubtless a much enlarged schedule, embracing the principal varieties of fowls, will be adopted next year.

The sweepstakes classes were very poorly filled, although many of the birds were of considerable merit. The pens belonging to Mr. Turner, of Sheffield, were need.

Too much praise cannot be given to the President, Vice-Presidents, Committee, and the Hon. Secretary (Mr. J. W. Thompson), for their admirable arrangements, and the careful and able manner in which they were carried out. The Riding School is very spacious and lofty, with a temperature during the day rather colder than suitable at this season. We doubt not, however, the Committee will remedy this slight defect on a future occasion. We merely mention this, not by way of complaint, but as an improvement necessary to the comfort of the birds.

The Single Game Cocks were divided into three classes—namely, Black Reds, Brown Reds, and "any other variety;" the two former containing many perfect birds, while the latter were only indifferent.

Black Reds numbered twenty-four, Mr. Fletcher gaining first prize with an excellent bird, closely pressed by Mr. Dodds for that honour; the third prize being awarded to a well-known old

cock shown by Mr. G. Hellowell. The highly commented cocks of Mr. C. W. Kellack and Messrs. Julian and Boys were also very much admired.

Brown Reds numbered fifteen; Mr. Fletcher winning the first and third prizes, the former with a magnificent bird, which also won the silver cup for the best cock in the Exhibition.

In "any other variety," Duckings took first and second, the third prize falling to a White.

Game Hens formed a very fair class, numbering twenty-two pens. J. Firth, Esq., the President of the Society, was successful in securing first and second positions with good Brown Reds and Duckings respectively.

Both varieties of Spangled *Hamburghs* competed together. A good pen of Gold were first, also winning Mr. W. Leeming's special prize; Silver second, and Gold third. Pencilled *Hamburghs* were likewise classed together, the Gold variety taking precedence.

The sweepstakes for *Game Cockerels* contained thirteen entries. The first prize was awarded to a good Brown Red belonging to Mr. E. Aykroyd, which, however, changed owners, having been claimed.

The *Sweepstakes* class for Dorkings does not require particular mention. In the similar classes for Cochins and Spanish Mr. Stretch and Mr. E. Brown each sent a good representative.

The *Game Bantam Cocks*, although a small entry, were of especial merit, the first-prize bird, a Black Red, belonging to Mr. John Crosland, jun., being a gem, and in miniature a perfect Game fowl.

We published the prize list last week.

BIRMINGHAM PERIODICAL POULTRY AND PIGEON SALES.—The Sale on Tuesday last was attended by fanciers from all parts of the country, attracted, no doubt, by the disposal of Mr. H. Tomlinson's surplus stock of Buff Cochins. These birds, twenty-five in number, made from 30s. to £5 each. There were some very fair pens of Spanish fowls, and some good Aylesbury Ducks, which realised remunerative prices. The Pigeons were not in such force as usual, but comprised some good Dun Carriers and Fantails. No pair, however, made over £5. Mr. J. B. Lythall, the Secretary of the Birmingham Cattle and Poultry Show, officiated as Auctioneer.

CAN POULTRY BE KEPT TO PROFIT?—"Fifteen Silver-pencilled *Hamburghs* laid, from the 1st of January to the 31st December, 2764 eggs—about 180 per fowl—the market value, £7 12s. 3d., and the cost a fraction over 3d. per pair per week, or £5 10s. the lot per year. These were kept under many disadvantages—a small yard, with only now and then a run into an orchard and field; and everything, except green vegetables, to buy at the dearest rate. I do not think that, under any circumstances, fowls can be kept in good condition for less than this; and no one kind of food can ever be called the best, for change of diet is their very life, the very thing they need, either as laying hens or chickens growing up for the table. Their food should be of good quality, and they should be well supplied with clean water. The Silver-pencilled *Hamburghs* are small, plump birds; when three months old equal to a good Partridge. The flesh is white and delicate as that of a Dorking. There can be no doubt they might be reared at small cost."—(J. M. Matthews, in *Mark Lane Express*.)

AUSTRALIAN GRASS PARROQUET BREEDING IN ENGLAND.

The Australian Grass Parroquet breeds freely in confinement in this country. The cage should be square, of a middling size—2 feet 6 inches by 2 feet by 15 inches, with wire front only. Place at one end a rough box about 18 inches high and 7 inches square, covered with dry moss to represent an old stump, and having a hole large enough to allow the birds to have easy access. Place a tray or half a cocoa-nut shell inside, containing the nest already shaped, composed of dry moss, grass, and wool, similar to what Canaries build with, with some loose in the cage. Place the cage in a retired situation. Feed the old birds on canary seed; when they have young add boiled egg, millet, and maw-

seed, and when long grass is in seed let them have a bunch of it hanging up. The price is about 25s. per pair.

I do not know of any instance of Love Birds breeding in confinement.—W. G.

APIARIAN NOTES.—No. XVI.

MY APIARY IN 1861.

(Continued from page 128.)

No. 7.—I have stated in No. XIV. of these notes (page 347), that this hive perished from an attack of wasps, after the loss of all the queens on the issue of the second swarm. A few days ago I paid a visit to an apiary of mine at some distance from my residence; it is under the care of my man, and most useful assistant in all appertaining to apian matters, which will partly account for my not having been there for some months. There was one stock working most beautifully, carrying in great quantities of pollen which fairly puzzled me. What hive could that be? The adjuster No. 7; but that I thought was dead. Then my adjutant came to the rescue of my bewildered thoughts. Yes, certainly, he had obtained leave from a cottager to drive a lot of bees doomed to the brimstone-pit; these he had brought home and had transferred to this box of empty combs. I now also remembered that, having previously broken up No. 1, (the united half-straw and octagon-box described in page 346) the bees of which went to strengthen an artificial swarm, the upper straw half, containing more than 20 lbs. of sealed honey, had been made use of for the purpose of supplying No. 7 with sufficient food for the winter. I was rather curious to see where the inmates might be collected, and accordingly turned up the super. I am bound to confess that the greater portion of these were in the super, and it appeared very evident that breeding had commenced there. We should expect this would be the natural result when there is no honey at all in the lower compartment. The bees are already clustering down through the central communication, and I do not think it will be very long before the breeding will be almost entirely carried on in the lower box. But I must admit, in accordance with the views of your northern correspondents, that during some part of this winter the lower hive might, in all probability, have been removed quite destitute of bees.

No. 8.—A Langstroth frame-hive, is tenanted by an artificial swarm. On the 9th of August I removed a frame from my Ligurian-hive, containing brood in all stages after brushing off the bees. This with three others was arranged in a four-frame nucleus-box; and having removed No. 11 (a strong colony) from its stand, the nucleus, being substituted for it, received the bees which returned from foraging. On the 14th a royal cell was in progress, and another brood-comb was given. The small box was then sent out to my friend, Mr. Woodbury's apiary, in order that the young queen might be properly impregnated by a true Ligurian drone. His pugnacious bees made such a vigorous onslaught on the intruder that he was obliged to request their removal, and they returned with woefully diminished number.

Being absent from home on a fishing excursion, the box was left undisturbed until the 27th, when I found not only a sadly reduced population, but very little honey—thanks to the robbers. There was a particularly poor-looking royal cell, from which I supposed nothing very good could be likely to issue; however, on the 31st I was gratified with the sight of a very fine queen. I now sent the hive out to the garden of a relative in the vicinity of Mr. Woodbury's drones, and on September 13th the queen had commenced laying. As there was a great deficiency in bees on the 14th, I drove No. 1, captured the black queen, and united the bees to No. 8. I had previously secured the Ligurian mother, which was confined in a small perforated zinc box inserted among the combs. On the 15th the frames and bees were transferred from the nucleus into a full-sized hive; some combs, obtained from No. 1, having been temporarily suspended in the frames, were added to the four already in the possession of the bees. The queen was liberated on the 16th, and I have no doubt was immediately killed. It is probable that she was retained a prisoner too long, and was weakened by her confinement.

On the 20th many royal cells, occupied by the brood of the defunct Ligurian queen, were in progress, and on the following day the hive was again sent out to the garden adjoining Mr. Woodbury's apiary. A queen emerged about the beginning of

October, but I had no hope or expectation of her becoming a fertile mother, as there were very few drones left in my friends' hives; the few there were had been chiefly bred in worker-cells by drone-breeding queens, and the weather was rather unfavourable for the flight of drones. The hive was allowed to remain for some weeks, when it was brought back to its stand in my town garden. The bees that were the progeny of the monarch which had such a very limited existence, were very good and fine Ligurians—so I trusted that the queen, if fertilised, would turn out all right and true; but no sign of breeding greeted my inquiring eyes at any time during the remainder of the year. On the 1st of February, I carefully searched every comb and could find no trace of a queen of any sort; so concluded that having remained unimpregnated the bees had destroyed her, or that in some way she had become lost. Possessing a tolerably large number of inhabitants, I resolved to unite them to a neighbouring hive, and, on the 20th, actually removed half the frames, brushing off the bees for the purpose of compelling them to occupy as small a number of combs as possible. Fortunately I could not decide at once which of my hives most needed an addition to its population, so the union was delayed for two days; when, on again inspecting the frames, I was gladdened by the sight of sealed and unsealed brood and a quantity of eggs. On another comb I discovered a somewhat diminutive queen. My resolve was quickly taken; so, instead of uniting these bees to others, I removed five frames with all the bees of the next box, No. 10, which, as I have previously stated, had become minus a queen, and added them to those of No. 8. A small amount of fighting ensued, but there is every reason to hope that the union will be the means of establishing one of the strongest colonies in the apiary. The foregoing case is chiefly noteworthy, owing to the very late period of the season when the queen was raised. It also proves the dangers to the queen which attend the joining of bees; the energy with which they set about repairing their loss; and the careful search which is necessary before deciding that no queen exists in the hive.

No. 11.—Early in the season this was a common straw-hive, marked down in the list as in good condition. Having completed two Langstroth-boxes, I was anxious to see them tenanted. As my apiary contained several straw hives, I resolved to transfer both combs and bees of some of them into these new boxes.

On May 4th I commenced with No. 11, from which all the bees were in a few minutes effectually driven out. The combs were cut out with considerable difficulty, owing to the presence of two horrid sticks thrust across the hive by its original proprietor. By means of a little paring, and by the aid of small sticks and wire, the combs were fastened in the frames. The box was put on the old stand, the bees were knocked down by a rigorous stroke on the upper surface of the bars, and in a few minutes had disappeared among the combs. During the succeeding week, at intervals of one or two days, the frames were taken out, the artificial supports to the combs removed when practicable, and the combs themselves pared where too thick, or where the bees had united them together; so by degrees the frames were brought to occupy their proper positions. A comb full of brood was taken away at the time of the transference; again on the 24th; and lastly, on August 14th. Also to strengthen another stock (No. 6). See page 347) a transposition between it and No. 11 was effected on May 15th, greatly to the gain of the former. It was once more removed from its stand for the purpose of obtaining bees to form the nucleus of No. 3, as already described: nevertheless, in spite of all these deprivations, I obtained in supers 24 lbs. of beautiful honey; and it remained at the end of autumn, and is at this present time a fine populous stock.

No. 12 was also a common straw hive. My friend Mr. Woodbury having presented me with a supermumery unimpregnated Ligurian queen, I was anxious to put her at the head of a stock. Confined in a small perforated zinc box, I placed her under a tumbler over the central hole in the top of a hive until I could succeed in preparing a proper habitation for her. Thus she remained one night, and in the morning was in a sad state from the condensed moisture and vitiated air. Although a pouring wet day, I drove No. 12, and with very little trouble succeeded in dislodging all the bees. The swarm was put into a frame-hive, No. 14, which occupied the old stand. The straw stock, No. 12, which contained a large quantity of brood was removed to another apiary. The queen-box with the imprisoned Ligurian was secured among the combs. Owing to the state of the weather no bees were out, but it was necessary to obtain a

sufficient number to bring the brood and eggs to maturity. A hive was taken away and No. 12 substituted for it. The first was turned up, a great many bees took flight to resent the insult. A few tapers and enough soon found their way into No. 12.

The following day the queen was liberated, but was lost either at this time or soon after. From the immense quantity of brood the bees soon became very numerous, so that on the 19th of June it was in a condition to part with sufficient bees to people No. 13, by transposition, after that hive was driven to form another artificial swarm. I do not think there could have been any queen at this time as so many of the bees left it, that it was necessary the following day or so to rechange the two hives. I was not at this time aware of there being anything amiss, but having waited in vain for any signs of young bees with the Ligurian type, it was at length very evident that the Ligurian queen at any rate had never become naturalised at the head of the colony. A common queen from a cottager's doomed hive was at length added, and was at the head of affairs on the 13th of August, when Mr. Woodbury in the course of one of his driving operations, at a place fully two miles off in a straight line, discovered that the young queen in one of the stocks must in one of her rambles have met with one of his Ligurian drones, many of the young bees bearing unmistakable evidence of Ligurian blood. Anxious to see what this queen might turn out in the future, he requested me to put her at the head of one of my colonies. Fixing on No. 12 for this purpose, I determined on establishing another Langstroth-hive. The bees were expelled, the queen secured and destroyed, the combs cut out, and four of the best secured in frames. No brood was visible, therefore two brood-combs were taken from No. 6, the little box with the queen tied to one of the frames and all left for that day. On the following, the slide was drawn and the prisoner liberated, in this case to be joyfully received by her new subjects. On the 27th, I discovered her to be quite safe, and she had laid a great number of eggs. I had the pleasure of again seeing her yesterday (February 22nd), she is a very fine queen, and has deposited a considerable quantity of young brood. Some of the bees hatched last autumn have the Ligurian marks very decided, though not nearly so good a colour as the true breed, or of the progeny of a true Ligurian mother impregnated by a black drone. All that I have had an opportunity of seeing of these latter are, in appearance, quite equal to those brought forth by queens true in every particular.—S. BEVAN FOX, *Exeter*.

(To be continued.)

BEEES DYING FROM DYSENTERY.

Just eleven months ago I penned the following passage which then appeared in your pages. "I never in my life had dysentery in a hive, and know nothing practically regarding it." I now regret to say that this blissful state of ignorance exists for me no longer. My acquaintance with this formidable enemy commenced this winter; three of my hives having been attacked. In spite of a prompt exchange of floor-boards, and afterwards of boxes, the first queen succumbed on the 17th of January, when those of her subjects which survived were united to one of the other infected stocks. Ten days later the queen of this colony likewise met the same fate; when the whole of the remaining bees were united to the third diseased stock. Upon this, the sole surviving remnant of what were originally three good stocks, I tried every remedy which my acquaintance with bee-books, or the experience of apianian friends could suggest. The floor-board was changed morning and evening, and the hive itself more than once; syrup flavoured with rum administered, and salt strewn on the floor-board; but all to no purpose—the rate of mortality remained unchecked, and it appeared merely a question of a few days as to when the queen herself might share the fate of the majority of her subjects. Under these circumstances I resolved to abandon the colony to its fate, and remove the queen with nearly all the brood-combs to a healthy stock whose sovereign (a drone-breeder) had previously disappeared. This resolution was carried into effect on the 3rd of February, when the surviving queen was introduced to, and cordially welcomed by, her new subjects. Notwithstanding this deprivation the colony still survives, and the mortality has greatly diminished; although it is difficult to say whether the decrease in the number of deaths is to be attributed to the virulence of the disease having abated, or to the few victims which it finds among the present scanty population. On changing the floor-board,

on the morning of Sunday the 16th ult., I found the detached covers of two queen-cells, one of which was so attenuated, that there appeared little doubt that the royal occupant which it had protected had arrived at maturity; whilst the other, retaining its full density, afforded presumptive evidence that its unfortunate tenant had met with an untimely end. A careful inspection of the interior of the hive, which I made next day, proved these inferences to have been perfectly correct. A virgin queen was discovered perambulating the combs; whilst one naturally-opened cell, and the mangled remains of three others, showed that she had lost no time in gratifying the remarkable instinct which impels a queen bee to the remorseless slaughter of her younger sisters.

Next followed an examination of the hive to which the queen and most of the brood of this unfortunate colony had been transferred. A number of young bees were found to have issued from their cradles; whilst the queen had not only supplied their places with eggs, but had extended her ovipositing to the adjoining combs. This leads me to remark, that all the queens of these infected stocks manifested the most remarkable fecundity almost up to the very hour of their decease. It would appear as if, whilst the colony itself was threatened with extinction by the ravages of this fell disease, nature impelled the royal mother to the utmost efforts to recruit the fast-diminishing population.

A distant correspondent, who had written to me for advice in a similar emergency, says, "I think I shall save one of my infected stocks. The other is hopelessly gone—not a bee left, but about half a dozen pounds of honey. The queen, I conclude, had fallen a prey to disease and died. The other I took up, and on examination discovered not to be so bad; and since I gave them a good dose of Mr. Bevan Fox's cordial,† they have recovered from their supineness, and now take the food from the bottle at the top, resenting every insult, so that I begin to think they are not valiant! I hope to be able to bring my three stocks through, since it is very disheartening to see a fine colony or two swept from before your eyes without being able to rescue them."

I shall be heartily glad to learn that my correspondent's hope has been realised, and that his experience of the effects of dysentery has been less fatal than that which has so recently fallen to the lot of—A DEVONSHIRE BEE-KEEPER.

RAISING AN ARTIFICIAL LIGURIAN QUEEN.

IN reply to "A YORKSHIRE BEE-KEEPER," he will probably see in a chapter of "Aparian Notes," already in the hands of the Editor, a description of the mode in which my No. 8 hive was established. The plan adopted was much the same as he suggests, and a sufficient number of bees were obtained. Whether the Ligurian workers are retained on the brood-comb or not, is, I think, a matter of little importance. In the instance referred to, they were brushed off prior to removal, and none but black bees—returned from foraging—with the brood-comb and two empty combs, constituted the nucleus from which sprang the future stock. After the lapse of two or three days the combs were inspected near dusk, the presence of a royal cell ascertained, and every black drone caught and killed on the spot. The hive was at once closed-up and transported to an apiary which contained none but Ligurian drones. In this way the young queen was properly impregnated, and would most probably have been the best Ligurian queen in my apiary had not the unlucky accident occurred to her as related. The queen raised from her brood is living and breeding, but it remains to be seen what her produce will turn out.

If "A YORKSHIRE BEE-KEEPER" wishes to maintain an un-mixed apiary of Ligurians, let him send away all black bees from their vicinity. He can then remove a brood-comb, best, probably, with the bees adhering; shift a strong common stock, putting the nucleus in its stead. Feed the nucleus with boiled white-sugar and water. At the end of three days inspect, destroying all black drones. If one or more royal cells are in progress, confine the bees, and remove to the apiary of Ligurians. As

Her majesty had evidently a very lively recollection of the fright she had previously sustained in being caught and transferred to a strange hive, I could not find her on any of the combs; and at length, when all had been removed, I discovered her almost alone, trying to hide herself in a corner of the box.

† Syrup flavoured with rum is dignified by my correspondent with this title, in consequence of Mr. Fox having suggested it to me as a remedy for dysentery.

soon as he has ascertained that the queen has commenced breeding he can strengthen the hive by giving brood-comb from his hives of the common bee, which he will find much safer than to attempt any subsequent joining of adults.—S. BEVAN FOX, *Exeter*.

BEEES IN COURT.

DEVON INTERMEDIATE SESSIONS.—Before Sir John B. Duckworth, Bart.

Charles Hill, a carpenter, was indicted for stealing on the 3rd of February, a hive of bees, half a pound of honey, and a stand, the property of George Ellis, yeoman.

Mr. Holdsworth prosecuted, and Mr. Carter defended.

Prosecutor stated that he saw the hive quite safe on the 2nd of February, and missed it the following morning. On the 10th of the same month he saw it in the shop of Mr. Edmund Whitmarsh, ironmonger, of Newton Abbot, and recognised it as his property.

Mr. Whitmarsh stated in Court that he wanted some honey, and for that reason purchased the hive, giving 7s. 6d. for it.

Mr. Carter asked the prosecutor how he became possessed of the bees; and, if he bought them, did he remember the saying that bees never thrived if they were bought or sold? Prosecutor replied that he found them.

Q. Did you find the owner? A. No.

Q. Did you try? A. Well, any one might have had them if they could recon them.

Q. Well, I suppose they were not ear-marked. (Laughter.) Cross-examination by Mr. Holdsworth elicited that prosecutor did not find the butt, but only the bees—the former he purchased. Mr. Carter: Then did you put the bees into it? A. Well, I shook them into it. (Laughter.)

Here the prosecutor was about to remove a part of the stand from the butt, when several of the bees escaped from "durance vile;" and, much to the horror of those present, flew about the court with great activity. The Hon. Chairman, after a short time, succeeded in obtaining silence, and the case was proceeded with.

Mr. Carter thought it preposterous to attempt to identify bees, and assured the bench that the butt was no agreeable sight in Court, seeing that so many of its inmates had escaped.

Verdict, "Guilty." A previous conviction having been proved against the prisoner, he was sentenced to twelve months' imprisonment with hard labour.—S. B. F., *Exeter*.—(Western Times.)

OUR LETTER BOX.

ELIAS IS POLLTRY (*Constant Subscriber*).—The hen, in all probability, has no access to dust, which is the cure for all vermin. It is most essential that, during the short time a hen is off her eggs she should have every comfort and convenience. Food and water are essentials—the dust bath is necessary. No hen will sit closely and well if she has vermin. Let a heap of dust be placed close to her food and water, and if she is much troubled, mix to a bushel of dust half a pound of black sulphur.

DEFORCED FOWLS (*Regular Subscriber*).—The only method we know of correcting a crooked tail, is by fastening the rump so that it must remain straight. This can be done by strapping, or by a piece of silver wire passed through it and fastened. It is rendered much easier if the tail-feathers are pulled out before the operation.

SICKLE-FEATHERS OF BUFF COCHIN-CHINA COCK (S. H.).—The white edge of the sickle-feathers are no disqualification. The tail of a Buff Cochin cock may be black, or nearly so; or black edged with white, or mixed with white. The shape of the tail is more important than its colour. If we were asked to state the most desirable shape, we should say a rich red bronze, like the side of a Golden-pencilled Hamburg cock's tail. In all varieties the tail becomes white as the bird gets older.

POLLTRY-KEEPING (Z. A., *Dartmouth*).—Your hive will be quite large enough for six hens and one cock. Let the floor be the earth levelled and covered 2 inches or 3 inches deep with sand, so that the dung, &c., of the fowls may be readily raked off. The nests are best on the ground, and may be either made of wood or wicker-work. The perches are best made of larch or fir-jules about 3 inches diameter, sawn down the middle, and fixed with the round side upwards. A small glazed window is always desirable. A coloured Dorking cock, and six Buff or Partridge-coloured Cochins-China pullets, would suit you best, as you require them for use and not for exhibition.

In our "Foultry-Book for the Many," which you can have free by post from our office for seven penny postage stamps, you will find full directions for making nests, feeding, &c.

PIGEONS (*Pigeon*).—The true Blue Rock is too wild and intractable, and, therefore, rarely found in Dovecotes. Try the Rants, they are the largest variety and not bad eaters.

YIELD OF BETTER (*Overdressed*).—Mr. R. White upon the Oakley Park farm found that in summer, when the pastures were in best condition, that the average yield from eight Alderney cows was 1 lb. 8½ ozs. of butter from three pints of cream; and from eight Kerry cows 1 lb. 4½ ozs. from the same quantity of cream, 16 ozs. to the lb.

METEOLOGICAL OF THE WEEK.—At Chiswick, from observations during the last thirty-five years, the average highest and lowest temperatures of these days are 50.9° and 33.7° respectively. The greatest heat, 67°, occurred on the 19th and 20th in 1836; and the lowest cold, 17°, on the 20th in 1845. During the period 133 days were fine, and on 92 rain fell.

CROCUSES.

HE other day I had a most capital text from a reverend gentleman, whose interesting letter will be found in another column of this Number. It was in these words: "I have two beauties now out, one is *Crocus lagenaeformis*, a glorious deep orange yellow, and would be most valuable to those who grow shaded ribbons, as it would shade off with the common yellow and Cloth of Gold, and they are all three out together

—that is to say, on the 1st of March in the west of England. Although we have done more for the Crocus in these pages than most of our day and calling, that text tickled the ruling passion to such a pitch that I could not get it out of my head without an attempt at discoursing on it in all its bearings.

In the first place, the word Crocus has not found a place in any living language except our own since the Latin ceased to be such. It was given by Theophrastus, and the next we hear of it is as the name of a love-sick swain from the same race as Garibaldi. The lady love was a beauty supreme, and her name was Smilax, but she was more daff than the lady who refused the laird of Cockpen, and the Italian Crocus was less fortunate than the Scotch one. He died broken-hearted. The notion at that time—the time of Augustus, second Emperor of Rome—was, that when the body died the soul went into something else, and it was said that the soul of Crocus went into a pretty flower which carpeted the Campagna of Rome; and that flower holds the name to this day.

What an absurd story, most would say; but when I assert it is taught in the best modern schools of Europe and in those of the Federate and Confederate States, and that no man can get into holy orders in the Church of England, or in the Church of Rome, or yet in the Kirk of Scotland, unless he can repeat that story better than I can; and, moreover, that there is nought against it in the "revised code," there surely must be something in it, if not the spirit of Crocus, and my attempt will be to find out that something, and tell you all about it.

The story about Crocus did not attract the attention of botanists earlier than the time of Linnaeus in 1737, and he only knew two kinds of them—*vernus* and *sativus*, the spring and autumn Crocuses, which he included as two varieties of one species. In 1797 Willdenow formed these two into two distinct species, and we have them now as he then left them. But long before those periods practical men took to the family of Crocus, and we find that Parkinson, in 1629, described twenty-seven kinds of spring Crocuses, some of which have been lost; and Miller, in

1763, described four wild species of them, with twelve varieties of spring Crocus and four varieties of autumnal ones. His fourth species, *biflorus* (*spatha biflora*), is the biflorus of the present day, and the Scotch Crocus of the trade, Miller being the first authority in print for the English name. He describes the Scotch Crocus "with very narrow leaves; out of the sheath arise two flowers. The flowers are of a dirty white outside, with three or four stripes in each segment, the inside of the petal is of purer white." Weston, in 1771, compiled a list of which forty kinds were of spring Crocus; but it has not been received as genuine. Dr. Goldbach, in 1817, published a monograph of the genus in the *Memoirs of the Imperial Natural History Society of Moscow*, vol. v. M. Bouche made the same attempt in 1826 in "Linnaea," but subsequent discoveries soon rendered both incomplete. M. Gay, of Paris, had long been preparing a monograph of the genus, collecting from all quarters and cultivating them in the garden of the Luxembourg under his own eye, which monograph was published in 1831 in the "Bulletin de Ferrussac." In 1826 Tenore and Bertoloni published papers on Italian Crocuses, and additions were since made by various botanists between Madrid and Athens.

Here, in England, Mr. Haworth published, in 1809, a paper on the cultivation of Crocuses in the "Transactions of the Horticultural Society," vol. i., page 122, in which he described thirteen species and varieties of Crocuses, eight of them being then considered as species. In 1828 Mr. Sabine, the Secretary of the Horticultural Society, began publishing his papers, on spring Crocuses only, in the "Transactions" of the Society, after being a collector and grower of them for thirty years; but, like a great practical gardener as Mr. Sabine certainly was, he confined himself almost entirely to garden seedlings and spring-flowering Crocuses, and said little or nothing of autumnal kinds, or about wild species. "Those spring plants," he said, "of which I propose to give an account may all, with the exception of *Crocus pusillus* and of the native British *C. vernus*, be considered as garden productions, or if not originally so they have been so long in cultivation as to have very much deviated from their native types. . . . Those I propose to describe, and under which the varieties in the garden of the Horticultural Society have been arranged, are *C. Susianus*, *C. sulphureus*, *C. stellaris*, *C. lagenaeformis*, *C. luteus*, *C. biflorus*, *C. argenteus*, *C. pusillus*, *C. versicolor*, and *Crocus vernus*; all without doubt, with the exception above stated, ancient occupiers of the flower-border, but only recently distinguished and separated from each other."

Mr. Sabine divided all the spring Crocuses into three classes. In the first class are all the yellow and cream-coloured sorts, twelve in number, beginning with the Cloth of Gold, and as far as I can make them out, the whole of the twelve are referable to *Crocus lagenaeformis* of Salisbury in his "Paradise Londinensis," 1805, except the Cloth of Gold; and *lagenaeformis aureus*, one of the twelve, is the very plant named in my text. It was afterwards figured by Sir J. E. Smith in his *Prodromus*

of the "Flora Græca," vol. i. fig. 21 (perianthis aureo concolore) it is also figured in the "Botanical Magazine," t. 2986, in the "Botanical Register," and in "English Botany," t. 2616: so that my text plant can very easily be verified. Dr. Sibthorp says it grows in sand upon clay; and Dr. Herbert adds, "Certainly all the varieties of this species (*lagenæiflorus*) seem to prefer a very light soil upon a clay subsoil, being planted 5 inches or 6 inches deep. *Aureus* so treated produces seed abundantly; planted near the surface upon sandstone, or in a damp situation, it thrives ill, and often perishes."

This last quotation is worth a cloth of gold. I have only studied *Crocuses* for the last six years, and I feared we were out of seeding kinds of *lagenæiflorus* altogether. And as the Dutch growers seem to have only the *lagenæiflorus luteus*, the large Dutch yellow *Crocus*, which is as barren, from long propagation from roots only as a rule, we were not likely to get much improvement from Dutch culture into our very earliest spring *Crocuses*; for the yellow kinds of this *lagenæiflorus* and of *reticulatus*, to which Cloth of Gold belongs, and that Cloth just as barren from the same cause, are the first to bloom of all our spring *Crocuses*, just as the purple sorts of *Crocus vernus* are the latest we have to bloom in April; and the rage for large kinds of the breed of *versicolor* by the public is fast depriving us of all our very late *Crocuses*, and confining the blooming season of *Crocuses* to the month of March only. Then having a good seeder in my text plant, which is of the truest and earliest kinds of all shades of yellow, we ought not to lose sight of it, and every seed it produces ought to be saved as carefully as those of any plant in the garden until we have a whole race of February flowers from them, and get the best of them into the Dutch market, from whence they would soon get into great favour with the public. On the other hand, the very late varieties of *Crocus vernus*, as *aprilis* and *tardiflorus*, and some others of Sabine, ought to be sent into the trade exactly in the same way. Then suppose all that done, we should then have full three months of the spring as gay with *Crocuses* as we now have them for six weeks only. But I would yield at much higher game, for I am persuaded there are materials within our reach to render the season of *Crocuses* as gay and as full and varied from the 1st of September to the middle or end of May. Before I am done with my text, I hope I shall be enabled to prove this point to the satisfaction of most of those whom I should like to bear a hand in the application of my discourse.

The second class in Mr. Sabine's arrangement includes all the "spring *Crocuses* with varied coloured flowers (not yellow), having the mouths of the tubes without hairs." For this class eighteen kinds could then be found to answer to the "properties," the chief of which was the absence of hairs in the throat, the best feature by which they could be parted from the great mass of *Crocus vernus*, the varieties of which are readily distinguished by having the mouth of the tube, or the throat, filled up with hairs. The great mass of the Dutch *Crocuses* now in the market fall into this smooth-throated class. Our best white, best purple, and best feather shades from white to lilac belonging to it, and they all of them bloom in March, and are all referable to *versicolor*, which is a native of Nice and other places on the borders between France and Italy. When I tell you that the gentleman who first brought this fine *Crocus* into notice in 1808 is still hale and hearty, and, as I have just said, that *Crocus* is the parent already of all our best new *Crocuses*; moreover, when I affirm the fact, that there are twelve more kinds of wild *Crocuses* just as good as this *versicolor*, and some of them much better and blooming from November to February, I hope you will agree with me in my idea of having *Crocuses* eight months in the year as plentifully as we now have them in March.

J. Bellender Ker, Esq., then the "Mr. Gawler" of the "Botanical Magazine," and the "Dodman" of recent date, was author of *versicolor*, "Botanical Magazine," 1110. Dr. Herbert who studied the genus for thirty years with the keen eye of a practical botanist, says that *versicolor* and its allies—that is to say, three more kinds which grow near Naples, in Corsica, and in Sardinia, and called *Imperatorius*, *sarvæolens*, and *insularis*, like the wild *lagenæiflorus* like to have their bulbs or corms deep set in the ground. The prevailing colour of these wild kinds of *versicolor*, like that of their great grandchildren now in our gardens, is white, sometimes suffused with purple, and generally more or less richly streaked with purple on the outside. And six more kinds of the same breed as the Scotch *Crocus* (*annulatus biflorus*), make up this second class of Mr. Sabine's arrangement. His third and last class consisted of "spring *Crocuses*

with various coloured flowers (not yellow), having the mouths of the flower-tubes hairy." Thirty years since the great bulk of the *Crocuses* belonged to this last class, all of them derived from *Crocus vernus*, and from a few of its wild varieties. Mr. Sabine had fifty-seven kinds of them, which he divided into seven sections according to the colour and markings of the flowers. The seventh section of which, however, is of any value in these days, and I want most particularly to inoculate the genuine spirit of a thorough-bred florist into every single individual reader of this Journal, if I knew where to get the inoculating lymph, in order to set us all running and racing after the April, the May, and the June-flowering wild kinds of *Crocus vernus*.

All the very late spring *Crocuses* are of some shade of purple up to lilac, and are descendants of two or three wild kinds of *Crocus vernus*, natives of the south of Italy. The smallest kinds are from *Crocus alpinus*, first mentioned by Mr. Sabine, and possibly yet in Middlesex; and it would be an excellent one to get seedlings from.

Crocus vernus aprilis of Sabine is admitted by that name by Dr. Herbert, as a true wild kind of *vernus* without any locality being assigned; but it must be in the south of Italy, and, probably, on some of the sub-alpine ranges going into Calabria. Mr. Sabine says of it, "Too much cannot be said of this variety. During the whole of the first part of April it renders the garden gay with its richly coloured and numerous blossoms." The "rich colour" being a fine violet purple tint. This, also, was a seeder and would be most valuable now. *Crocus vernus neapolitanus* of Sabine, was a garden plant and figured as such in the "Botanical Magazine," t. 2240; but the wild Neapolitan *Crocus vernus* blooms in Italy as late as June, piercing through the snow. Dr. Herbert says, "The finer purple Neapolitan variety inhabits the loftiest mountains of Calabria and Lucania, not descending lower than 5000 feet. On Monte Polino it flowers as late as June and July, reaching an elevation of 6000 feet. On the Wengern Alp its flowers actually pierce the remaining snow in June." Now, who will join in an excursion next August to the top of Mount Polino, and get a quart measureful of the seeds of the finer purple Neapolitan *Crocus*, and a basketful of the "roots?" or shall we let M. Louis Van Houtte, of Ghent, steal a march on us and bring it into the Belgian market first, or is it already in England? Dr. Herbert had it at Spofforth, but what became of his rare collection of *Crocus* I never heard.

Dr. Herbert's enumeration of the whole family, as far as they were known up to 1846, was his last contribution to practical and to scientific botany, and one of the most really useful of all his labours in that line. It was just ready for the press when he died, and it was edited by Dr. Lindley, and published in the Journal of the Horticultural Society at the end of 1847—a very unfortunate time for the family of *Crocus*, for, what from being then at sixes and sevens amongst ourselves, and from all our subsequent "proceedings" being on the sliding-scale system downwards till a recent period, the public at large took very little heed of our "Journal," and I mean to try and see what can be done for this alpine family in THE JOURNAL OF HORTICULTURE, as soon as it can find room for me and them, or most of them. Meantime I would propose a regular hunt for all the very early and very late spring *Crocuses* from the end of January to the end of August.

They were to be had in England in plenty as late as thirty years back. Now, there are hardly half a dozen species in the hands of the Dutch growers for supplying all our wants, and of them most of us are content with the strain of three of these species. First, they have the Saffron *Crocus* (*sativus*); secondly, the *vernus*, then *versicolor*, the pride of our pluck; after that *lagenæiflorus*, and last of all, *biflorus*, or Scotch *Crocus*, which, by the way, is not a species but one of the varieties of *Crocus annulatus*—not a rap more to go to market for. But if I could get the steam on I should have "a Sardinian correspondent" for my own self; another at Trieste, to hunt up and down both sides of the Adriatic, and cross it as far out to sea as the season suggested, searching the Ionians from either side as the wind permitted. But the best wild kinds of *Crocus vernus* are from the steppes behind Odessa.

One would think that *Crocuses*, which are all so much alike and which, in a wild state, appear to have a decided preference for calcareous, and hilly or alpine regions, thus exhibiting one constitutional tendency, would readily cross and be improved that way, but the contrary is the fact; no one has yet succeeded in getting hybrid *Crocuses*—that is, between distinct wild species.

There may be cross-bred varieties, and Dr. Herbert thought he had succeeded in getting a few hybrids, but only one or two that he was sure of, after an experience of thirty years.

I have had a touch at them, and I have now in bloom evidences that the best pure whites, the best purple, and the best feathered purple, lilac, and white of the Dutch growers come just as true from seed as the species—that is to say, that 75 per cent. of their seedlings are just as the parents, and the rest improvements on or inferior to their original kinds. No one of them comes more true than Sir Walter Scott and Queen Victoria. From a patch of either of these seeds enough will ripen to produce a row of the sort one mile long. I made that calculation, reckoning twenty flowers in the patch. The easiest way to fill the three king-ions with Crocuses to line both sides of all the railways would be this: To mark the best flowers now; to gather the seed at the end of May or before the pods burst; to keep it in the pods one month, and at the beginning of July to draw drills exactly as for Sweet or pot Peas; to sow the Crocus seed about as thick as garden Peas should be sown in January—that is, pretty thick, to allow for a picking to the birds, and to have a full crop besides; to drive down a stake at each end of the rows, as for marking Asparagus-beds; to let the “roots” flower before they are disturbed; and to pick out all the bad ones, leaving the best to finish that season’s growth. Many will bloom the third season, and some not until the fourth; but much depends on the goodness of the soil, and it cannot be too good for them. The seed-pod is always underground, and comes up to the surface only when the seeds are ripe, and that generally when the leaves are ripe also, and as some of them seed like weeds, the pods should be caught as soon as their heads appear, to destroy them if the seed is not wanted, for nothing spoils effective arrangements of the flowers so much as self-sown seeds, unless the roots are taken up every year. Many kinds of the very old Crocuses are now quite barren from having been propagated only by the roots.

None of the Crocuses are natives of England, though in some places, as in the extensive meadows at Nottingham, they have taken the same hold of the soil as native Crowfoots, having first escaped from cultivation. In the same way, the most tiresome weed in the market gardens between Richmond and Battersea, is a native of Mexico, escaped from Kew Gardens within the memory of persons still living there. No one knows where the Saffron Crocus (*stivus*) is a native of; but as Saffron first acquired celebrity in Asia, it is presumed to be a native of some parts bordering on Syria. The Arabic name, *Zafaran*, and the Moorish and Spanish names, *Azafran* and *Safra*, go a good way to uphold that opinion. The Italians call all Crocuses *Zafferano*, and the French *Safran*, so that a Sardinian correspondent, if sent from Sardinia, would need to know all that, if only to assist him with the natives in hunting them out. If ever I send out a collector of Crocuses, I shall first tell him where to begin on the coast of Portugal, thence to both sides of the Pyrenees; and Italian Alps; then on to Dalmatia, the Banat of Hungary, and the Balkan to the Bosphorus; back again to the blue bells of the Carpathian ridge and South Podolia, thence by Odessa to the Alma, Inkermann, and Kertch; then across to Caucasus, to the head of the Caspian, and lastly to turn to the right to Mount Taurus, return by Damascus, and take all the islands of the Mediterranean on his way home, after picking up the only sort in Africa on the hills near Tangiers.

D. BEATON.

THE CAMELLIA AND ITS CULTURE.—No. 4.

TEMPERATURE.—It is really wonderful, so to speak, how accommodating Camellias are. In some places you will find them growing and flowering in delightful profusion among a miscellaneous collection of plants—such, for instance, as those possessed by your fair correspondent “A. Z.,” who, with praiseworthy zeal, has managed for a number of years to have many choice flowers to please the eye, while at the same time and in the same house she has been able to obtain fine fruit to regale the appetite. Here is a fertility of expedient, and a practical exemplar of what can be done by those ladies who take a lively interest, as this lady has done, in the doings and success of cottage garden societies. In order to set ourselves right, however, with your fair correspondent, while applauding her efforts and success, we beg to remind her that now-a-days it requires all the efforts of first-class gardeners, with first-class accommoda-

tion, to produce first-class samples of either fruit or flowers in return.

There can be no better place, then, for cultivating Camellias to the highest state of perfection than a house specially set apart for their use. Comparatively, few private places in the country can boast of such a structure, and yet there are not many species of plants under cultivation that offer a better speculation with the same amount of care. The demand is almost unlimited, from the positive large to the superlative largest, from the two-shilling up to the twenty-guinea plant, and why? because the plant in the three-foot or four-foot tub is just as healthy and as likely to be so for half a century to come, as the plant in the 6-inch pot. Those that have houses of the above description will have the very important advantage of letting the plants have the temperature best suited to their wants. There will also be less manual labour required; for, as is well known, where the accommodation is limited and the demands for space from other subjects entitled to your distinguished consideration equally pressing, it is then absolutely necessary to be fertile in expedients—moving this section here *pro tempore*, and that section there, and maybe balled to meet your requirements in such a way as you would wish. Such is no exaggerated picture of the majority of garden establishments from March till May.

But observe, that if there is a demand for a succession of bloom for a period of eight or nine months in the year, one house will not be sufficient. One uniform temperature for the entire collection throughout the season will not be effective in its results. You may select early-flowering sections and late-flowering sections, and after bud-formation keep some of the earlier in-doors, and some of the later out-doors, and by this method occasionally secure a six-months succession, which, in many cases, will be all that is requisite. Much, indeed, depends upon climate. In this cold, northern locality upon the banks of the fresh-water Clyde, where we have a long winter and short summer, and all the evils concomitant with an excessive rainfall, it is highly injudicious to place Camellias out of doors; for even with the best drainage and most careful attention they will get so saturated that you cannot depend upon them retaining their buds. I agree with your very able correspondent “D. Deal,” that this is one of the prime causes of failure. I may add I am very much pleased—indeed, it would be the merest affectation to conceal it that some of my remarks have met with the approbation of a gentleman of his philosophical and practical knowledge. It was our practice for a number of years to place them out of doors as soon as their buds were properly developed; but we never could count upon that success which has uniformly attended our efforts since we kept them at all times under glass; not that it is absolutely necessary to do so where climate is favourable and rainfall moderate. It is our opinion, that at that particular period of annual development they require all the solar light possible, without, recollect, being subjected to the direct rays of the sun; so that, if all other things were equal, a shaded, sheltered situation out of doors would undoubtedly be preferable.

In order to insure a lengthened period of bloom, it is necessary to divide them into three sections—the early, the ordinary, and the late. Some may be inclined to combat this point, and lead respectable proof of certain results with less systematic appliances. If you wish to make certain secure, we always think it is wisdom to work on a preconceived plan; to adopt that which experience proves effectual, and to modify or discard altogether that which may not be suited to localities, circumstances, and such like. Our plan, then, is to select a batch of those which have a tendency to bloom early and to bloom successfully; for if you attempt to get Duchesse d’Orléans, Teutonia, Valteverado, and some others before Christmas, they will not expand to the very centre of their bud; at all events you cannot depend upon them (some of the varieties even with the very best treatment, flowering at the most suitable time, have a tendency in this direction), whereas Fimbriata, Alba plena, Imbricata, Lady Hume’s Blush, Saccio nova, Henri Favre, and some others will bloom well at any time they are called upon and prepared for. We have a batch of the above that bloom from the end of September up to Christmas. These are what we call the “early section,” and this the prescribed time. They are cleared out of the conservatory as they are done blooming, and transferred to a cool vinery. The vinery in question, we begin to force never earlier than the third week in January, and never later than the first week in February. This batch has a clear month’s rest, some of them move at a minimum temperature

of not less than 31°, and not more than 45°. The wood-buds began to be pretty prominent just as the house is prepared for forcing, and they come away at a gradual rise of temperature suited to the progress of the Vines. I may here state that this section scarcely, if ever, drops a bud. Many of them, on the contrary, have freely to be disbudged; and I can, with the greatest confidence, rely on them if they are in proper condition at the root.

I now redeem the pledge I gave in one of my contributions to THE JOURNAL OF HORTICULTURE with reference to variegation in flowers. I mentioned that I had hit upon a plan for insuring every individual bloom of *Camellia Imbricata* to come blotched, and not only does *Imbricata* come so, but all those which have the least disposition to variation. In the course of experience, I observed the flowers that had a tendency to sport were very much superior as sports if they happened to be in bloom during December and the early part of January. I noted the fact particularly, and further observed those that unfolded their petals in March and April had very much less inclination to sport; many of the plants showing a large majority of self flowers, and those that were blotched only very partially so. I resolved definitely to test the value of the hypothesis formed within my own mind, and selected three or four plants of *Imbricata* that had done blooming in the beginning of March. These were placed at once into a temperature ranging between 50° and 60° during night, and 10° or more higher during the day; they were subjected to strong heat, and proportionate abundance of moisture until they had formed their flower-buds, and were then transferred to a house where they had abundance of air during the day, and a moderately warm temperature, caused by early shutting-up the ventilators during the night. This treatment continued to the end of August, after which they had free ventilation both night and day. They succeeded quite as satisfactorily as their congeners, showing abundance of bloom, and some of them opened their first flower early in October, continuing to bloom until new year's day. I need only add that every individual bloom was all that could be desired for sportiveness, and gave the most unqualified satisfaction. Poverty at the root, in general, is one of the best means for promoting variegation in leaves. The plants that produced these flowers were as liberally treated as the most robust samples in the collection, and the foliage was rich in chlorophyll; on the contrary, one or two tiny examples of the same variety produced small flowers with no disposition to variation. Several authorities in chemistry aver that plants give off oxygen by decomposing carbonic acid during the day, and absorb the latter again at night; whereas flowers perform a somewhat different function, by absorbing oxygen at all times and emitting carbonic acid. It is true, nevertheless, that flower-buds do not differ essentially from leaf-buds, and in many instances, the apportioning of them is within the control of the cultivator. Such is an epitome of our practice with reference to those classed under the "early section," which includes all the varieties that we wish, and can trust being speckled and spotted.

Those classed under the "ordinary section" are placed in the vinery mentioned above, as soon as they are blooming in the conservatory. The last flowers, especially during March and April, are not quite expanded when the leaf-buds burst and the young leaves are in process of elongation. By this time the Vines have made considerable progress, and afford by their leaves sufficient shade to the tender shootlets from a scorching mid-day sun.

Those classed under the "late section" require to be treated as much as possible consistent with success in blooming them. A sprinkling of *Camellias* in bloom during the month of May is certainly, as they always are, a nice feature in a mixed collection of plants. The length of the day, however, and the great call upon the physical energies of the plant render the blooms comparatively short-lived. It is absolutely necessary, in the first place, in selecting a batch for flowering at this period to fix upon *bona fide* late bloomers. As I suggested in a former communication, *Bealii* is one of the best for this sort of work, along with which might be named *Candissima*, *General Zucchi*, *Princess Barchiochi*, *Duchess of Buccleuch*, *Cap of Beauty*, *Archiduchesse Augusta*, *Rubini*, *Cavendishii*, and *Festivi*. They should be wintered in a temperature at a minimum of 34° and 40°. On one occasion, I retarded *Bealii* in a house where the temperature occasionally fell to the freezing-point, until the second week in June, some stray blooms remaining ten days longer. I opine that most people know, that as the *Camellia*

will stand as much heat with superabundant moisture as any plant under cultivation, so will it also live and thrive in some way when subjected to rigorous cold. I have known *Camellia*-stocks to live over a severe winter out of doors uninjured, when the young shoots of the Portugal Laurel were nipped. It is not advisable, albeit, for those who wish to grow them as decorative plants, to subject them to a temperature under the freezing-point. From March till the time of flower-buds expanding, this batch ought to be kept as cool as possible, with rather an over than an under proportion of moisture in the atmosphere. An exact counterpart of an atmosphere that is required to winter successfully soft-wooded greenhouse plants. It is almost unnecessary to mention, that that part of the house where they are located should be shaded from midday suns to modify the temperature. By following up this method with two years' preparation, you may calculate upon being in a high degree successful. The stated period of retardation, and the sequent process, mark you, is after their buds are properly formed. There must be no "hungering" them of temperature at the proper time. They require when done blooming as high a temperature as any of the other batches, as many of them will not bloom annually otherwise, and some of them cannot be coaxed by any means.

It remains for me only to state, that the temperature for their successful cultivation throughout the year, should not be a sudden transition from a low to a high, and *vice versa*. It is necessary that this should be thoroughly understood, for inattention to small matters, and this among the number, at a certain stage, is also one of the causes of bud-dropping. A low temperature during the development of the young shoots, as well as during the greater part of the process of consolidation—at all events until the foundation of the structure so rapidly called into being exhibits some degree of strength and flexibility—is inimical to bud-formation. You may err as much as you please on the side of heat, with corresponding moisture and proper shading, with desirable results; but by all means try to place them in an atmosphere between 55° as a minimum for night, and 90° as a maximum for day temperature, and if you are right in all other respects you will have flower-buds in abundance.—JAS. ANDERSON, *Meadow Bank, Uddingstone*.

COMPARATIVE COST OF WOOD AND IRON FOR HORTICULTURAL ERECTIONS.

I WRITE to give my experience as to the above.

Having a wall of brick already erected (which must be taken into account as between a span-roof and a lean-to) 300 feet long, I wished to have 50 feet glazed as a lean-to, and having been told that iron houses were the best, and were made and sent ready to be fitted together, I applied to a builder of that sort of houses. The estimate sent was an uncertain one, from £110 to £120. I then applied to our own carpenter, who contracted to make it of best Dantzic timber for £110s., and not to exceed £12. Of course, I chose the latter, and the house was commenced ten days ago, and is nearly finished. One-half of it is glazed. I sent exactly the same measurements to each party. The iron builders' estimate included ventilation. The carpenter's did not, so I must add that to the sum of £12. Ten of Moore's patent ventilators at 14s. each will be £7, making the total cost £19, instead of £110 or £120.

I have a wooden vinery, and added an iron one to it of same pattern. It was done by our country whitewash at a much cheaper rate than that of the estimate of £110, comparing length and breadth of the two.—A SUBSCRIBER.

CYCLAMEN EUROPEUM.

MR. BEATON desires us to thank "T. C." for the anomalous *Cyclamen europæum* which he sent. Mr. Beaton says he never saw the like before, and was not aware that the European *Cyclamen* ever assumed that character, or that it was a native of so far south as Genoa. It has been often asserted that it did not extend beyond the Po. Have you seen it in flower in Savoy? If not, depend upon it the plant is verum. This plant was dug up in 1860, in a rocky district ten miles south of Genoa. The leaf is exactly that of *europæum*; but the species is very variable in the form of the leaves, and it has the gouty spur on the top of the bulb which is the chief characteristic of *verum*; the leaves and the flowers come from that spur and not from the body or crown of the bulb in the usual way.

Such Cyclamens, probably, could be propagated from cuttings just as easily as Gloxinias. The spur cut into as many pieces as there are leaves on it, every piece would make as lawful a cutting as any from the stem of a Begonia.

The seedling from "a genuine eum" is a true cross between it and persicum, not vernum, and there are many just like it in the Wellington Road Nursery, where a lovely race is now really splendid and well worth going to see. But what shall we say if persicum was not the father?

Pray arrange "your facts and thoughts" on Cyclamens, and, as soon as convenient, let us have them in full. There is one fact that Cyclamen people ought to know, and it is that there is a decidedly distinct species of Cyclamen now in bloom with the Messrs. Fraser, of Lea Bridge Nursery, that has not yet been described, unless it was by Dr. Sibthorp in his "Flora Græca." We have seen the kind in bloom three or four years since.

PROTECTING SEED FROM MICE.

To prevent the ravages of mice in sowing Peas, the following plan has been used with perfect success:—The Peas are first soaked in water for an hour, then drained from it; and to a quart of the seed stir in a good tea-spoonful of resin in finest powder. It in no way injured their growth, and was a perfect preventive to the mice touching them.

A friend of mine has lost by mice all her Gladioli bulbs. I have a large number to plant, do you think I may adopt the resin for them, of course not soaking the bulbs, but only moistening them to make the resin adhere?

Is *Yucca gloriosa* *superba* quite hardy, so as to be planted on a lawn?—A SUBSCRIBER OF FOUR YEARS.

[Powdered resin is not a novel suggestion as a protector of Peas against mice; but moistening them to induce the powder's adherence, we think, is. If the powder will protect Peas, we have no doubt that it will equally protect Gladioli bulbs.

The *Yucca* is quite hardy enough to endure our ordinary winters on a lawn.]

THE MANETTI ROSE STOCK.

MR. BEATON is full of experience in many things, as I am sure we are all willing to testify; but he is but a youth in Rose culture, or he would not have said, page 445, "You will have no end of trouble if you bud Manetti stocks from a nursery—you will never be free from Manetti suckers as long as you live." This seems to me discourteous in the extreme to a body of most respectable men, and is, moreover, as far as my experience has gone, entirely incorrect; for it implies that Manetti stocks bought from a nurseryman would poison the ground with root-suckers, or "spawn," as such things are often called.

I repeat that, although I have known the stock thirty years, I have never seen it put forth root-suckers to any extent; so that to verify his prediction that those who buy Manetti stocks from a nursery will never be free from them, the buying cultivator must cut off the stem-suckers and make cuttings of them, as they will not spread of their own free will like Raspberries or Dog Roses. My conviction, with regard to the non-effect of cutting out the buds, dates about ten years back, although long antecedent to that period I had made it a common practice; but I think it was soon after then that I found out the only method to keep the dormant buds from breaking was to bury the stem. Experience gave the hint after this manner. I much wished to have near my house a bed of those most brilliant, but rather delicate-growing Roses, Comte Bobrinsky and Comte d'Eu, budded on stems about a foot in height, and so I had Manetti cuttings carefully disbudded and budded with them. They grew well the first year, the stocks not having got a firm root hold; the second year the stems commenced to burst with vitality, and numerous clusters of stem-suckers made their appearance—these were removed very frequently, but the heads languished; the third year there were more stem-suckers than ever, and my favourite Roses became mildewed and died. I observed this propensity of the stock, even when budded with comparatively free-growing kinds, if any considerable portion of the stem of the stock was exposed to the air, and this led me to that most successful method, now general with all who understand Rose culture—viz., to bud very low and bury the stock; to plant the cuttings—as directed in my last paper; to transplant

them, and bud as near the root as possible. In early times, probably before Mr. Beaton ever heard the name of this stock I used to have the cuttings planted in ridges (they were always, disbudded just as we do Currant cuttings), the earth drawn away and the buds inserted; but the ridges in hot weather became dry, budding was difficult, and the plants, although vigorous, were not well rooted; so as soon as my stock allowed me to do it, I had the cuttings transplanted after remaining a year in the cutting-bed, and this method I still practise.

If the soil of Mr. Beaton's garden really does induce this stock to put forth root-suckers, so as "never to be free from Manetti suckers;" I should feel much gratified if he will one day leave a specimen at your office. I know so well how capricious soils are in their effects upon trees and plants, that although I have never seen a Manetti Rose full of root-suckers, I should not be surprised at seeing one.

It will require two or three years before I can again test if disbudded cuttings will put forth suckers from their stems when exposed to the air; but I shall, if spared, "try again."

In writing about this stock, I hope I have not penned a sentence tinged with asperity or discourtesy. Mr. Beaton's experience seems to differ so widely from mine, that I felt compelled to notice it.—A NURSERYMAN.

P.S.—I accept Mr. Beaton's challenge which he gives, page 477, in nearly the following words:—"I will disbud any Rose-shoot of last season's growth, or the leading shoot of any tree or plant in our climate, and I will challenge, after doing it, all the practice of Europe to get one single cluster of buds to grow from any one of them." I shall, therefore, beg my old friend to accept of a few young trees of *Rhododendron ponticum* to disbud. How delighted he will be to find not a cluster of buds only, but every portion of the stem alive with them, if the plants are treated kindly.

[This comes of jumping at conclusions from what appears in the columns for correspondents, the particulars which guide the answers not being known. I said nothing about root-suckers in that answer, and the "NURSERYMAN" said there are two sorts of suckers. I would lay my head to be shaved if there is one nurseryman in Europe who could keep the Manetti Roses, which were described to me in that question, from producing suckers as long as the plants lived. The plants were little "stools," with from three to five shoots issuing from the collar, and there were two layers of growth in them. And I am ready to prove that no man on earth could keep these plants from throwing up suckers from above the collar to the end of their lives. I have been too long on the turf, and I am too well known to take any offence at the charge against me for discourteousness. Everybody tells me I am too much of the other way, and they say what everybody says is true.—D. BEATON.]

ROSE CUTTINGS.

IN THE JOURNAL OF HORTICULTURE, Vol. I, page 307, you say that "the last half of March is the best time for making Rose cuttings. Three-inch little side shoots slipped off with a heel the best sort of all Rose cuttings."

By these "three-inch little side shoots" do you mean the young tender shoots of this year, or the ripened wood of last?—A ROSE-FANCIER.

[The ripened shoots of last year.]

ICE-STACKS.

HAVING, at the suggestion of my worthy employer, adopted ice-stacks for preserving ice, I write to state that I have every reason to be perfectly satisfied with the result of twenty years' experience. We never fail in keeping it for twelve months, or much longer if it were necessary. On the 18th of January last, when I had the heap uncovered previously to putting together another year's supply, there was a large body of ice left (which is not disturbed), and is sufficient to have lasted till midsummer. On one occasion the house was supplied with ice from the same heap for two years.

Believing the method we adopt to be the most certain and the most simple way of keeping ice, I will give my practice in detail.

The situation of the heap is a dry loamy bank, surrounded with large Beech trees, which partially shade it from the mid-

day sun. It is 30 yards from the pond and 6 feet above its level. It requires ten men for three days to put up the heap, and the way we proceed is as follows:—We use a boat to break and float the ice to the side, which is thrown out and broken just sufficiently small for the barrows; it is then wheeled to the site, and thoroughly broken as it is thrown down. I have sometimes used a little snow with the ice, which saves considerable labour in breaking. When the heap is about 4 feet high the ice is wheeled upon planks, lifting them higher as the heap progresses, which when finished is in the shape of a cone 12 feet high and 15 feet in diameter at the base. It is then covered a foot thick with clean Beech leaves, and in about three weeks we give it another covering of leaves of the same thickness; a few branches are then thrown over the leaves to keep them in their place, and the ice is secure.—J. GREENSHIELDS, *The Gardens, Sarsden, Oxon.*

COCOA-NUT FIBRE REFUSE.

You were not much in error in saying it could only be obtained here; because, if it can be got elsewhere we believe it must be from parties who are infringing Barsham's Patent, which has not expired. We have, from the date of the patent, been interested in it, and are now the sole proprietors.

It is only two weeks ago we succeeded in obtaining a verdict in an action against one Pulsner for infringing this patent. The trial, a short statement of which is given in the *Times* of the 26th of February last, lasted three days. Some few years ago a person at Bristol was using our patented process, but we understood he discontinued after a notice from us. Should he or any one else be doing it there now, we shall, of course, interfere.

Mr. Barsham gave the name of "pulp" to this refuse, but it is more like sawdust, though not so perishable. A large heap of it has been on our premises for nine or ten years, and it does not appear to be decayed in the slightest degree. There is a quantity of short fibre in it which answers admirably for draining at the bottom of flower-pots. In page 473, of last week's Number of THE JOURNAL OF HORTICULTURE, is described a method of making "hotbeds without manure." We have no doubt the cocoa-nut refuse would be an excellent material for such purpose, treated in the same way with less proportions of lime, acid, and water, and that it would retain heat for a very long period. In the International Exhibition we shall have specimens of this cocoa-nut refuse. You will observe by our advertisement that we supply small bagfuls at a low price; but if any person requiring a large quantity will write to us, we will make a great reduction in the price.—THE PATENT COCOA FIBRE COMPANY, *Kingston-on-Thames.*

SUCCESSION OF FLOWERING PLANTS IN BEDS.

WILL you inform me what plants would be suitable for planting out in beds with Asters, to flower in June, July, and August, to make a show till the Asters begin to bloom?—AN INQUIRER.

[Scarlet and Variegated Geraniums, Calceolarias, Verbenas, and blue Lobelias, with Variegated Alyssum—all bedding plants. Then Delphiniums, of which formosum and Hendersons are the two best for the purpose, and spring-sown Clarkias and Collinsias, with Gillias, and many other early summer annuals.]

MANAGEMENT OF TROPICAL FERNS IN POTS AND IN A ROCKERY.

I HAVE a considerable number of tropical Ferns, growing some in pots and some in rockwork. Will you tell me whether the first require repotting, and if so, what is the best time of the year for so doing? And, also, whether those in the rockwork will require fresh sod about the roots, and when should that be done?—LIVERPOOL.

[The best time for potting tropical Ferns is early in spring, the latter end of March will do very well. Ferns make abundance of fine fibrous roots, and, therewith, quickly fill their pots: therefore, they require repotting at least once a year. Some of the stronger growers may even require potting a second time in July, especially if fine fronds are desired. Young Ferns will be,

of course, in small pots, and when the pots are filled with roots they ought to be repotted directly. Ferns suffer greatly from drought. Indeed, when once the ball of earth becomes thoroughly dry the plants in nine cases out of ten will perish. If ever you observe them drooping very much, you had better place the pots in a vessel of tepid water and let them remain for an hour or two till the ball of earth and roots have become thoroughly soaked.

The proper soil for Ferns is a compost of two parts of sandy fibry peat, one part turfy, and one part leaf mould, with plenty of sand added. Mix them thoroughly, but do not sift the soil, and previous to potting let the compost be placed in a warm room to become aired and moderately dry. Then pot them, giving them a moderately liberal shift. Drain well with clean broken pots, covering the drainage with a layer of the rougher parts of the compost. Then place the ball in the centre of the pot and fill all round it with the compost, taking care to press it down pretty firm, and leave a space of the pot unfilled to hold water sufficient to wet the whole of the soil in the pot. When pots are filled quite full the water runs off over the rim, and then the ball does not get moistened, neither to the centre nor yet to the lower parts; consequently the plant is starved for want of water. This is a serious evil, and many a fine specimen has gradually sunk under such treatment. Avoid this error by leaving the soil in small pots a quarter of an inch below the rim; the next size half an inch, and so on till in large pots, an inch and a half of space to hold water is left at the potting time.

Your Ferns planted out amongst stones in the rockery style will be greatly benefited by a good top-dressing of fresh compost every spring. Previous to laying it on, scrape away as much of the old soil as you can without injuring the roots. If, however, you keep the rock stones moderately moist, the Ferns will grow there much finer than in pots, the roots will penetrate deep into the soil and find nourishment even from the stones themselves, for if you remove a stone placed near a Fern you will see the roots adhering to it like hay.]

APRICOTS UNDER GLASS.

MANY of your readers have, I doubt not, Apricot trees in orchard-houses now in full bloom; they should be most careful in giving them abundance of air. A cold north-east or east wind will, if admitted freely in the daytime, dry the pollen and assist in setting the fruit. Those who have travelled in the south of France in March when the Almond and Apricot trees are in bloom, and have felt that bitter "bise," or north wind, which seems to assist in setting the fruit, as the trees (unless injured by still hoar frosts) always bear abundant crops, will not fear to allow our comparatively mild March winds to blow through their houses.—T. R.

ADD GARDENS TO YOUR COTTAGES.

VERY recently the Rev. F. Trench delivered an admirable lecture to the Botley Farmers' Club on "The English Labourer in the different stages of his life." He sketched him from "schooling time" to ladship, from manhood to old age, pointing out truthfully, wisely, and eloquently what the labourer should do for himself, and what others should do for him in each of those periods of his career; for, as the lecturer observed, "the labouring man has claims upon us all which we ought thoughtfully to recognise, and manifest too, not in feeling alone, not in words alone, but in deed and in truth."

We regret that we must not devote space enough for large quotations from this lecture, but we will find room for the noble conclusion agreed upon by the assembled farmers; for it does them infinite honour, and is in unison with the efforts we have for many years directed towards the same object.

A discussion ensued, says the report, which turned principally upon the necessity of providing better cottages for the labourer, the evils which arise from taking children too early from school, the beneficial results of the allotment system, and the prejudicial effects of the law of settlement, after which the following resolution was submitted to the meeting and agreed to:—

"The condition of the farm labourer in the various stages of life can be very much ameliorated by providing him, as near as possible to the scene of his labour, with a cottage containing sufficient rooms for the security of the comfort and morality of his family, and a moderate amount of garden land

not exceeding one-sixth of an acre, but regulated by the size of his family, and sufficient to raise vegetables for his family, and employ his surplus labour without encroaching on the strength due to his employer."

To that resolution we give a hearty and unreserved assent; for the result of half a century's observation of the labourers with the plough and the spade is fully in unison with the opinions which that resolution embodies. A garden is a blessing placed at the disposal of the cottage tenant; it supplies him and his with healthful food and healthful occupation; adds another charm to his home, and whatever renders that attractive weakens the attractive power of the beer-shop. We, like the lecturer, have known many a labourer at the close of life clinging with fondness to "his old beloved cottage"—and we can add with unexaggerated truth that it has been in every instance a cottage with a garden.

MR. WILLIAM PAUL'S NURSERIES, WALTHAM CROSS.

THE name of Mr. William Paul is familiar to every lover of the Queen of Flowers as an authority to whose decision all her subjects bow; and now that she is beginning to develop her budding honours, a visit to his extensive grounds will amply repay the horticulturist, whether amateur or professional, for the time which he may thus employ. And from what we know of Mr. W. Paul—and we have known him long—we can assure the intending visitor, to whichever class he may belong, that he will meet with every facility in examining the treasures which this establishment contains.

Spending most of our time in the great city, a run into the country is a rarity to us, even when there is something particular to be seen; and though hardly prepared to expect much at this season, we resolved on a trip into Hert, where, out of the reach of the turmoil and smoke of the town, oxen are still to be seen at plough, and windmills still picturesquely crown the distant eminences despite the invading power of steam. Availing ourselves, however, of this, we were in half an hour at the Waltham Cross Station, to the platform of which Mr. Paul's grounds immediately adjoin, and for the benefit of our readers we will now endeavour to detail what we there saw.

On entering the nurseries by the walk which leads by the side of the railway we noticed a number of Roses trained against the paling and apparently not long planted, but which, when full grown, will afford an admirable screen. Farther on we came to the ground devoted to the growth of fruit trees and hardy shrubs, occupying an extent of thirty acres, the soil being a fine mellow loam, between 3 feet and 4 feet in depth, with a substratum of gravel—admirably adapted for fruit trees and indeed all kinds of plants, so friable that on touching it where it had been thrown up it fell to pieces like slaked lime, and to use a term not recognised by chemists, but well understood by gardeners, "fresh"—that is, free from the inert vegetable soil with which old gardens so much abound. Nearest the railway the soil is of a lighter character than elsewhere, being rather a light loam but not too much so—here are Rose-stocks by the thousand, or, rather, by tens of thousands, all waiting the process which shall convert them into the pride of many a garden. We also observed by the side of a grass walk running parallel to the railway a row, about 300 yards in length, of trees of such kinds as are most ornamental either by their flowers or foliage, or weeping pendulous habit; when farther advanced these will form a pretty background to the nurseries, and cannot fail to be interesting to the travellers who pass along the line. But alas! such is the rapidity of modern transit that there is scarce time to observe, and the objects have faded from our eyes—a pleasant memory and nothing more.

From this lower part of the ground a broad grass avenue, a quarter of a mile in length, leads to the offices and glass structures (though for use in wet weather, there is a gravelled path as well), and on each side of this avenue are alternately small circular and larger oblong beds filled with evergreens—such as Rhododendrons, Kalmias, Yews, &c., and a multitude of Holly-hocks. In the quarters adjoining we noticed Berberis aquifolium, even though not in flower looking very attractive by its deeply-coloured foliage, and showing for bloom. Also a fine stock of pyramidal Pear trees, healthy and clean as could be desired, with their buds just bursting. We must also not omit to notice a permanent lattice fence for training fruit trees

intended for cultivation against walls—such as Apples, Pears, Plums, Peaches, and Apricots; and when we state that the top rail is 7 feet from the ground, it will at once be seen that these fruit trees can be transferred to the walls in a bearing condition—an important consideration with all and especially with those who dread the verification of the saying, "He that plants Pears plants for his heirs."

Among Coniferae were several fine plants of Wellingtonia gigantea some of which were planted only a twelvemonth ago, then not more than 6 inches high, now 18 inches at least—a proof of how rapidly this valuable tree grows under favourable circumstances.

From considering these incipient giants we passed to some tiny individuals of the same family, only growing to the height of 2 feet or 3 feet. Of these there was a good collection, among which the Dwarf Spruce *Abies excelsa pygmaea*, *A. stricta*, with small bright green foliage; *A. Gregorii*, and *A. variegata*, with whitish or pale yellow leaves were the most striking; *A. Findoniensis*, which attains a greater elevation, is another kind with variegated foliage. There were also some fine plants of *A. Menziesii*, with vivid green leaves; and *A. Douglasii*, with bright green, somewhat glaucous leaves, forming in its native countries a stately tree of from 150 feet to 200 feet in height; the same kind of Pine in fact as that which furnished the lofty mast that is to be seen at Kew, and which created so much sensation at the time it was raised.

We were particularly struck by some specimens of a Black Yew, which was of a more branching and pyramidal habit of growth than the Irish, and better clothed at bottom where other kinds are apt to become bare and unsightly. Being also of comparatively slow growth it is admirably adapted for the centres of beds and for low hedges.

Having thus glanced over the hardy department, we will now pass to the houses which are situated near the high road leading through Waltham Cross towards Edmonton, and thence to London. They are all built on the same plan and heated by one boiler of the saddle description, having projecting wings at top so as to catch the full influence of the fire; it is, as near as we could judge, about 5 feet 6 inches in length, and in connection with it are about 2000 feet of pipe; but it is capable of heating a much greater extent.

All the houses here are numbered—a system worthy of imitation in other extensive establishments, if not for the sake of the persons employed, yet highly desirable for the convenience of visitors and for the purpose of description.

The first one which we entered was a span-roofed structure, 50 feet long by 18 feet wide, and 10 feet high on the inside. For the purpose of ventilation every alternate front light, each 4 feet long, is made to open by means of hinges and a quadrant arm, so that any amount of air can be given at will. Ventilation at top, a point which is too often disregarded, is also provided for by moveable lights which can be opened or shut by means of a pulley; it must be remembered that the tendency of heated air is always upwards by reason of its smaller specific gravity, and that if no exit be afforded for such air no efficient ventilation can exist. The glass used in this, as in all the other houses, is 16 oz., heded in putty and bradded down, but not putted above; glazed in this way very little if any drip occurs.

In this house were Tea Roses planted out in the beds last July, in a soil consisting of the top spit of an old pasture, dung, and some lime rubbish. A few Roses—such as Solfa-terre, Triomphe de Rennes, Cloth of Gold, Lanarque, and Gloire de Dijon, the latter of which had made before it was pruned a growth of 10 feet in length since it was planted, grew in the centre of the bed for the purpose of covering the roof. The beds here both in the centre and at the sides were surrounded by 4½-inch brickwork, coloured of a pale slate, which being of a subdued tone is found to harmonise better with the prevailing colours of the flowers than a glaring white. All the Roses were looking healthy, especially considering how recently they were planted. This house was very light and airy, and no artificial heat was afforded.

In the next house were some *Cinerarias* just coming into bloom, which will in another week present a gay appearance. Of the most forward were Smith's Brilliant, rich maroon; Othello, plum; and Flower of Spring, white, edged with rosy purple, very fine, large, good shape and habit, and a free flowerer. But far more noticeable here was a fine collection of Camellias on the stage in the centre, some of the most remarkable of which were Princesse Bacchiochi, mentioned in our last Number, page 471,

as having been awarded a Special Certificate by the Floral Committee of the Royal Horticultural Society; *Colvillea striata*, about 3½ inches across, white pink striped; another kind unnamed, with a magnificent waxy white flower with occasional pink stripes, and 4 inches across; *Eximia*, blood red, very full and fine; *Orobolucra*, one of the best of the cream whites; *Imbricata*, nearly 4 inches across, rosy pink; *Marguerite Gouillon*, rosy pink, streaked; *Conspicua*, very bold, and rather single, but the stamens very conspicuous, constituting a great part of the beauty of the flower, of free habit and fine foliage; *Saccioi* vera, imbricated, delicate pale rose; *Teutonia*, somewhat Ranuncul-shaped, the centre being much elevated, pink, with a wide white stripe down the centre of each petal; *Donekelsarii*, rather single, but very showy, and a free bloomer, crimson and white mottled; *Chandleri*, scarcely out, but among the finest of its colour, a vivid scarlet; *Saccioi* nova, delicate rose, but not fully out; *Alexina*, blush, striped with rose, not new, but very free and good; *Grinnelly*, anemone-flowered, and which on account of the great size of the flowers would have a grand effect when planted out in a conservatory; *Imbricata alba*, pure white, with pink stripe; but among pure whites the old *Double White* and *Fimbriata* are still two of the best of their class. It is almost superfluous to add, that all the above were in perfect health, with beautiful glossy foliage.

Along the side shelves was a miscellaneous collection of winter and early spring-flowering plants, consisting of *Heaths*, such as *hymenalis*, *Sindryana*, *Wilmoreana*, *Lambertiana*, a good winter kind; *Caffra*, small, white, with pretty dark centre; *Melanthera*, lilac, dark centre; *Mamma*, waxy rose; *Grandiosa* autumnalis, pretty white; *Perspicua* nana, rosy lilac; and *Rubricalyx*, white, rose calyx. *Boweiana*, white, and *gracilis* autumnalis, small but pretty, have been in bloom all the winter, and are still good. Among *Epacris*, *alba odorata*, *Aleana*, *Delicata*, and *Sanguinea*, were very fine and conspicuous. The *Bride*, and *Mrs. Pym*, the latter the very purest, are first-rate whites. *Cyclamens* were just coming into bloom, and there were also some fine Chinese *Primroses*.

In the next house was a large stock of all the leading varieties of *Roses*, in first-rate condition, and promising to be shortly a mass of bloom. The most remarkable of these was *H.P. Beauty* of *Waltham*, with splendid cupped flowers of a bright rosy crimson. The plants of this could be distinguished at a glance, by their vigorous habit and large foliage, and in another week they will be clothed with bloom.

Among other first-rate Hybrid *Perpetuals* the following are particularly worthy of recommendation, viz.—*Abd-el-Kader*, bright velvety purple, shaded with scarlet, large and very double; *Admiral Nelson*, perfect in outline, of a beautiful crimson; *Alexandrine Delfroy*, large and handsome, peach; *Amiral Gravina*, large and full, of a blackish-purple changing to amaranth; *Anna Alexieff*, large and full, rose coloured, a superb variety, of good habit; *Anna de Diesbach*, very large and showy, fine clear rose; *Belle de Bourg-la-Reine*, very fine, large and full, satiny rose; *Baron Gonella*, large and full, shaded pink and lilac; *Catherine Guillot*, perfect form, pink, very fine; *Celine Toursis*, large and full, fine form, brilliant glossy rose; *Clement Marot*, very double, rosy lilac; *Comtesse de Chabrilant*, beautifully cupped, pink, very sweet; *Darzens*, very large and double, rosy pink with yellowish centre; *Dr. Briere*, large and full, cherry; *Dominique Daran*, very double, dark crimson purple; *Duc de Cazes*, globular, blackish velvety purple; *Empereur de Maroc*, rich velvety maroon, very desirable; *Eugene Appert*, velvety crimson, fine foliage; *Eugenie Lebrun*, dark crimson; *François Arago*, velvety purple; *General Washington*, bright rosy red, particularly fine; *Gloire de Santenay*, scarlet crimson, very fine; *Jean Bart*, shaded red and violet, brilliant in colour, and very effective; *Lelia*, shaded rose, very large; *Louis XV.*, beautiful blood red; *Madame Bell*, very handsome, rose colour, sometimes edged with white; *Madame de Cambacères*, rosy carmine, fine form; *Madame Furtado*, very fine and full, rosy crimson; *Madame Pierson*, large and showy, rosy pink; *Mademoiselle Bonnaire*, exquisite shape, white, sometimes rose; *Modèle de Perfection*, lively pink, very pretty, and a free bloomer; *Prairie de Terre Noir*, velvety purple, one of the best; *Princesse Mathilde*, shaded crimson and purple, very fine; *Robert de Brie*, rosy salmon; *Rosine Pardon*, bright cerise, shaded; *Senateur Vaise*, very double, bright red; *Triomphe d'Alençon*, very large, bright red; *Triomphe d'Amiens*, vivid crimson, sometimes striped with lake, very fine; and *Victor Verdier*, rosy carmine, purplish edges, very showy and effective.

Of the other classes (*Bourbon*) *Victor Emmanuel*, purple and purplish-maroon, was very good; *Celine Forestier*, a Tea-scented *Noisette*, was a pretty pale yellow; and *La Boule d'Or*, Tea-scented, a fine golden yellow.

Two other houses were filled with large *Roses* for the May and June exhibitions, those for the former being just started.

Roses for the late exhibitions, *Azaleas*, *Rhododendrons*, *Kalmias*, and *Deutzias* occupy three more large houses; and in the propagating department we noticed a large stock of variegated *Geraniums* of all the leading kinds. Among the *Golden Chain* varieties *Mrs. Pollock* with a bronzy red horseshoe was particularly fine; this, with *Cloth of Gold*, *Lady Cottenham*, and *Golden Fleecy* may be considered the best of their class. We were here struck with a singular-looking plant being brought forward for propagation, and, on inquiring what it was, were told that it was a *Variegated Hoseradish*. Of course it was not in a state to judge what it would be like when fully grown, but Mr. Paul informed us that it was an accidental sport of the common *Hoseradish* which he found in his grounds, and that its leaf is yellow edged with white, and having a patch of green as large as one's hand in the centre, the whole presenting a most striking appearance. Being like its original, perfectly hardy, it is likely to form a valuable addition to the limited class of hardy variegated plants, and will doubtless be extensively used for winter decoration.

Before quitting the propagating-pits it may be mentioned that the beds of these are heated by three-inch pipes passing all round beneath the border, through which, as well as in the walls on each side of the path, there are apertures by means of which the heated air can pass into the atmosphere of the pit. The supply of top heat can be regulated or entirely cut off by closing these. Near the propagating-pits is the tank from which the plants in the houses are supplied with water; passing through it is the chimney of the boiler-house fire which thus imparts to the water a temperature frequently as much as 20° higher than would otherwise be the case.

We now come to the magnificent collection of *Hyacinths*—a flower with which Mr. Paul has been very successful at the spring exhibitions of previous years, and with which he is no doubt preparing to achieve fresh honours. The bloom is now in splendid condition and will continue in perfection throughout the month, during which time it will form quite a study for those who take an interest in this lovely harbinger of spring. For the benefit of our readers we noted down a few of the newest and finest sorts, a task—and we frankly confess it—of no little difficulty in consequence of the care with which the stock had been selected to the exclusion of all kinds of inferior merit.

The most remarkable in the several classes were *Double Reds*.—*Koh-i-Noor*, salmon red, new and very fine; *Lord Wellington*, pale rose, with handsome spikes and splendid bells; *Noble par Merite*, blush rose with dark centre, new, and very fine; and *Susannah Maria*, bright rose, very handsome spike. *Double White*.—*La Tour d'Auvergne*, pure white, one of the best; *Prince of Waterloo*, pure white, also very fine. *Double Blue*.—*Prince of Saxe Weimar*, dark blue, long and handsome spikes, not new, but very good; *Van Speyk*, fine lilac blue, very handsome. *Single Reds*, Amy, fine bright red; *Aurora Rutiland*, fine dark red; *Cosmos*, fine rosy pink; *Duchess of Richmond*, rich pink, fine spike; *Gigantea*, new, blush pink, with very close spike; *Florence Nightingale*, pale pink, with carmine stripes, large bells and splendid spike, quite new; *L'Étincillante*, bright crimson; *Lina*, bright crimson, new and good; *Lord Wellington*, rose, striped with carmine; *Milton*, shaded crimson, very fine; *Mrs. Beecher Stowe*, large and beautiful, pink bells, new and fine; *Mr. Macaulay*, rose, beautiful; *Norma*, splendid bells of a delicate waxy pink, very fine; *Sultan's Favourite*, large and handsome, blush striped with rose; *Solfaterre*, fine orange scarlet; *Von Schiller*, salmon pink, large spike, new, and one of the finest. *Single Lilac*.—*Honneur d'Orceen*, mauve, very fine. *Single White*.—*Alba Maxima*, splendid pure white bells, a new sort; *Grandeur à Merveille*, large pale blush; *Grande Vidette*, pure white, very handsome; *Madame Van der Hoop*, very fine pure white; *Mont Blanc*, pure white. *Single Blue*.—*Argus*, bright blue, white eye, very fine and distinct; *Baron Von Tuyl*, dark blue, particularly fine; *Charles Dickens*, a sort that always comes good, shaded porcelain; *Coronne de Cello*, azure blue, large and very close; *Grand Lilas*, porcelain, handsome spike; *Orondatus*, porcelain blue, very good; *Regulus*, light blue; and *William I.*, purplish-black, very fine spike. *Single Black*.—*General Havelock*, new and very handsome, and *Prince*

Albert are two of the best. *Single Yellow*.—*Ida*, very fine bright yellow.

For soil Mr. Paul recommends turfy loam, with a plentiful admixture of sand and well-decayed manure; but for plants in borders any light garden soil will do. Success in the cultivation of this plant depends in a great measure on the time of planting, and the manner in which that operation is carried out. If the bulbs are intended to be grown in beds, October or November is the time, the crowns being placed 2 inches below the surface, and further covered with a like depth of loose pulverised manure as a protection against frost. For pot culture the bulk of the roots should be potted in October, using pots much deeper and more upright in the sides than the common kind, but for early and late flowering a quantity may be potted in September and December.

In potting leave one-third of the bulb above ground, place the pots out of doors on a hard, dry bottom, cover with 6 inches of coarse sand, allow them to remain covered for a month at least, then take into a cold frame or forcing-house; keep near the glass when the leaves expand, and give plenty of air and water.

The shades of evening having now commenced to gather round us, we were reluctantly obliged to wend our way towards the railway station, without visiting the other portions of Mr. Paul's grounds, amounting to twenty acres more. But in passing along we had just time to peep into four large pits covered with a kind of tiffany, and filled with hardy plants which require a little protection when young—such as Holly-hocks, Roses, and young Conifers. Among others were some fine plants of *Cupressus Lawsoniana*, one of the noblest and most graceful of its race. Bits of this kind we were told could be constructed at a very trifling expense, and were found extremely useful in winter and spring for protection from frost, and in summer for protection from sun.

DOUBLE CYCLAMENS—COCOA-NUT FIBRE REFUSE—CROCUS LAGENEFLOLUS.

The following short extract will interest you: it is from "The Dutch Gardener" by Van Oosten, London, 1703:—"Speaking of 'the Sowbreads' he says, 'Of these there are several sorts—there is a double white one which bloometh in the spring, and is much esteemed, and it is said to have been brought from China; yet I believe it got from seed.' I suspect he is speaking of the Cyclamen persicum; but it is interesting as confirming our old friend Gilbert's statement of the existence of the double sorts—a fact that our present gardeners deny. It is rather an interesting little book and has some good ideas. He gives directions for growing dwarf pyramid Apples and Pears, the one on paradise, the other on Quinces. This will interest Mr. Rivers, and I will send him a note of it.

I have to-day seen your article on Cyclamens, and have learnt much about them that I never knew before. Clearly I have never had true vernum, so that if you are ever able to bestow a genuine seedling on me it would be most acceptable. Maund in "The Botanic Garden," vol. vii., has a plate of *C. vernum* which is altogether wrong; but in vol. viii., No. 708, he gives a drawing of one sent to him by my father (a capital gardener). He calls it *europæum*, and it flowers in August; but it has a very peculiar root (anemone radice), with short spurs upon it. Might not this be one of the parents you are seeking for vernum?

I think you and the writer in page 434 on cocoa-nut refuse are both under a slight mistake. I get mine from Bristol, and yet you have seen it and recognised it as the genuine article. I saw it produced from the crushing or tearing machine preparatory to making mats and brushes, and so is not the refuse from their manufacture, though I have no doubt the manufacturers use but one rubbish-heap for all the processes, so that there is a slight mixture of fibre with the sawdust. I first saw it used in the yard of a horse-auction, making a beautiful footing for the horses to exercise on. I at once saw it was too good for that purpose, and then came your notice of its uses.

I have two beauties now out, one is *Crocus lageneflorus*. I got it lately from my father in Devonshire. He long ago made an accurate study of the *Crocus* and *Narcissus* families, and had a fine collection. This *Crocus* is a glorious deep orange yellow, and would be most valuable to those who grow shaded ribbons, as it would shade off with the common yellow and the Cloth of Gold; and they are all three out together. My other beauty is

a pale lilac Anemone, rather larger than our Wood Anemone, and of a very lovely colour (the colour of *Lactuca scariola*, an uncommon colour). A friend sent me roots last year from the neighbourhood of Mentone. If I get any more good flowers I shall send one to your office to get its right name. The *Crocus* is figured in Salisbury's "Paradisus Londinensis."—H. N. E.

TRACING OUTLINES.

The French receipt for tracing outlines, asked for by your correspondent in No. 18 of your Journal, may be found in the supplement to the *London Review* of November 23rd, and is as follows:—

"Fix the paper on which the copy is to be made on the original, and moisten it with a cotton tuft dipped in the purest benzoin. The portions of the paper which have imbibed the liquid are at once rendered as transparent as prepared tracing-paper, and the original can be copied without the slightest injury to the drawing. Inks run freely without spreading, and the lines are more difficult to remove from the paper thus prepared than from common paper; lead-pencil marks being almost indelible. As the benzoin evaporates the paper becomes opaque, assuming its primitive appearance. If the liquid be pure and fresh distilled a little exposure to a current of air will remove all smell. If the drawing be large benzoin can be used as the work proceeds, and if any portions become opaque, apply more benzoin to that part."—A STERLING SUBSCRIBER.

THE FLORIST AND POMOLOGIST.

THIS monthly publication, which commenced with the present year, is a new and enlarged series of the "Florist," which work the "Florist and Pomologist" has incorporated with it, and describes itself as a pictorial monthly magazine of flowers, fruits, and general horticulture, and is conducted by Dr. Hogg and Messrs. Spencer and Moore—names which are ample guarantees for efficient and respectable management.

The size of the work is considerably larger than the "Florist," and, consequently, more suitable for a more perfect illustration of the various subjects with which it is adorned. The drawings which have appeared in the three Numbers issued deserve all praise, and are executed in the highest style by that renowned artist Mr. Fitch.

The January Number was illustrated with drawings of Sunset Geranium by Mr. Fitch, and Northern Spy Apple by Mr. Andrews, but the latter was incorrect in the drawing as regards the foliage. The letterpress comprised, besides copious notices of the subjects illustrated, articles on the Trebbiano Grape, by Mr. Tillery, Welbeck; the Chrysanthemum, by Mr. Holmes; the Pine Apple, by Mr. Thomson, Archerfield; the Rose, by Mr. Radclyffe; and several other articles and notices of gardens and nurseries, and copious calendrical directions for the month.

The February Number was illustrated with very clever drawings of Early York Peach and Bougainvillea glabra, and contained some very interesting and excellent practical papers. Among which were remarks on the local influences of soil and climate on a good many varieties of Pears, by Mr. Ingram, Belvoir; a very instructive paper on winter-ripened Grapes, by Mr. Thomson, Dalkeith; notes on some winter-flowering plants, by Mr. Henderson, Trentham; on French Pansies, by Mr. Deans, Bradford; on the Fig, by Mr. Barnes.

The March issue had drawings of a splendid group of new Chrysanthemums, admirably drawn by Mr. Fitch, with a list of new and fine varieties; and articles on ornamental-foliaged plants for grouping on lawns, by Mr. Fleming, Clevedon; on renewing vine-borders without losing a crop of Grapes, by Mr. Melville, Dalmeny Park; and several other practical papers.

The proprietors have expressed their desire to bring out a work worthy of the age, and the goodly array of names which have already given and promised their assistance, in conjunction with artists of first-rate reputation, cannot fail to lead to the realisation of their unbounded success. The articles which have already appeared in the pages of the "Florist and Pomologist" have been thoroughly practical, sound, brief, and to the point; and to all who are interested in all that is going on in the improvement of varieties of fruits and flowers this work cannot fail to prove of great interest and value.

FLORISTS' FLOWERS.

THEIR DISTINGUISHING CHARACTERISTICS, CULTIVATION AND VARIETIES.—No. 3.

THE PELARGONIUM.

If flowers could weep and know their losses, surely there is not one that would wear a deeper crape, or shed more bitter tears, than the subject of this present notice. It was only the other day that I recorded the death of one of its earliest patrons—the Rev. Richard Garth, of Farnham; and now, this morning, when I was cogitating over this paper, I received a note from my friend, Mr. Charles Turner, of Slough, informing me of the death of one whom I then spoke of as having commenced with him in the race, who carried it on much longer, and who, with the aid of his intelligent gardener, Mr. Nye, was the most successful amateur exhibitor of Pelargoniums—I mean Mr. Foster, of Clewer Manor, near Windsor. How striking sometimes are the coincidences of God's providential dealings, and what solemn strokes of the clock of time these are! Within a couple of months of one another these two giants of Pelargonium culture depart; and but a short twelvemonth ago, the genial and kind-hearted Edward Beck was called away! Surely I said rightly, the Pelargonium ought indeed to weep for its losses; and we, the younger, and yet the elder generation of florists, who have been so often delighted with their productions and who can tell those commencing the delightful pursuit what changes these men made, are yet a while longer left. Mr. Foster was not merely a Pelargonium-grower and raiser. He was a liberal encourager of horticulture generally, and not very long since I saw him, then a hale old gentleman, in the Slough Nursery making his purchases of new things—Conifers, if I recollect rightly. May his mantle fall on one worthy to bear it!

And, in truth, when one looks back on those days, and recollects the (what we should now call) Ragged Jacks which were then tolerated, and which their raisers assured us never would or could be beaten, one wonders at what we must call the audacity of Mr. Glemny, who ventured to draw the above representation of what a flower ought to be, and then told florists to work away until they obtained it. Well might they hold up their hands in astonishment, and ridicule the notion. But if it were audacity, it is the audacity of genius; and we have now in many of our best flowers, such as Mrs. Hoyle and Celeste, as great symmetry as is probably attainable. A Pelargonium ought to be quite circular, and to consist, of course, of but five petals. The ground colour in all to be of the same shade, and in the lower petals clear and bright. The upper petals should have the blotch dense and well defined, and a narrow edge of ground colour round the upper rim. The throat should be clear and free from stains; when pure white it is generally preferred. Spots on the lower petals have now brought us another class of flowers, while Fancies and French varieties make also additional ones. The present notice refers only to those known as show or florists' varieties. Some kinds are apt to burn, this is a fatal defect. From some cause (perhaps the flimsiness of the petals), the sun seems to scorch the upper petals at the edge of the dark blotch, and so gives it a discoloured and dingy appearance. This happens

generally with the darkest-coloured flowers; but now when we have so many good sorts of every shade of colour, it is certainly not to be tolerated. Stoutness of petal is also another property, which is second only to that of form, which I regard (despite Dr. Horner in the "Gossip for the Garden"), as still the very first requisite in every florist's flower, and it is quite evident, that when the petals are thin the flower is not likely to retain for any length of time its symmetrical appearance.

The character of the plant, too, must be taken into consideration. Loose and straggling growth may for a while be overlooked, but must ultimately condemn a flower. Thus, Wonderful, still a desired variety, would be much more so were it not for its long-legged habit, which makes it easily recognisable on a stage. With this must be coupled freeness of bloom. If a plant only throw up a few trusses, or if those trusses consist of only a few pipes, then the flower will not long last as a favourite. The French varieties generally are more free-blooming than the English ones; and the gentleman who is styled the Sardinian correspondent of Messrs. Barr & Sugen (though now, as he lives at Nice, he is in reality a subject of the French Emperor), assured me that his seedlings were exceedingly free in their blooming. I dare say some people will say, when they look at the figure, "Oh, we never see such flowers as that!" Pardon me, you do, or may do. The same gentleman showed me some dried blooms, most exquisitely prepared they are, which were perfectly circular, and this is the true way of judging of them.*

The cultivation of the Pelargonium has been so often and so ably touched upon in the pages of THE JOURNAL OF HORTICULTURE, that it may seem superfluous to add anything further; but a few remarks, more for the general cultivator than for the large grower or exhibitor, may

not be out of place; for although it is one of those flowers which will bear any treatment almost, it amply repays a little care and attention. It delights in a rich and strong compost: one composed of two-thirds good turfy loam and one-third well-decomposed cowdung will make a very good one. Leaf mould is used by some, but I think that it makes the soil too porous. Supposing your cuttings to be rooted (and they will strike anywhere—in a propagating-house, in a spent hotbed, or in the broad glare of sunlight and heat in the open border), they should be potted off in September into small pots, and there left until they have filled them with roots, then give them a shift into those in which you intend them to bloom. Six inches across will be large enough for maiden plants. This should not be done if possible later than the end of October or beginning of November, and by Christmas they ought to have filled the pots with roots. The young shoots should be pinched back so as to encourage a short stubby growth. All the work they do in the spring should show itself above. The rootwork should all be finished. To insure their doing this properly, they should be supplied with liquid manure, either in the shape of guano water or some other form.

* These are now to be seen, I believe, at Messrs. Barr & Sugen's.

Diagram of a Perfect Pelargonium.

When coming into bloom they should be shaded, and care must have been taken all through their growth to fumigate well against green fly, one of the greatest pests to which they are subject. When the bloom is over, water should be withheld from them gradually, so as to allow the wood to ripen, and this ought to be thoroughly the case before they are cut down. They should then be kept close and without water until they break. When the shoots are about an inch long they should be potted into smaller pots, and when these have been well filled with roots, again into the large ones for blooming. A little practice will soon enable a cultivator to grow them to his own satisfaction, even although the exhibitor and large grower may consider him but a "muff" after all.

As to varieties, their name is legion; I select a few I know to be good:—

Celeste (Hoyle), rich orange lower petals, dark maroon top, and orange scarlet margin, clear white centre.

Mrs. Hoyle (Hoyle), violet rose lower petals, small black spot on upper ones, shaded with red. Large.

Pruella (Hoyle), dark, rich, black top petals, narrow margin of bright crimson, white centre, lower petals prettily painted.

Ariel (Fellows), white, of fine shape and substance, dark carmine spot on top petals.

Carlos (Hoyle), an old but fine-shaped rose-coloured flower.

Czar (Hoyle), a large and striking painted flower.

Delectana (Fellows), an excellent and useful white.

Fairest of the Fair (Beale), white with long pink blotch. Very pretty.

Governor-General, an old but very favourite flower.

Lord Clyde (Foster), bright scarlet, good shape. A very fine loomer.

Norma (Hoyle), deep rose lower petals, maroon top. A large and fine flower.

Rosa Bonheur (Hoyle), very clear white throat, deep lake lower petals, richly tinted with carmine and black. Free, fine, and striking.

Volunteer (Hoyle), centre and edges of lower petals white, richly painted with waxy orange carmine. A fine and showy flower.

There are a great many others as fine, and, perhaps, finer varieties, but these have struck me as being very good, and, I should think, would please most people.—D., *Deal*.

A FEW DAYS IN IRELAND.—No. 17.

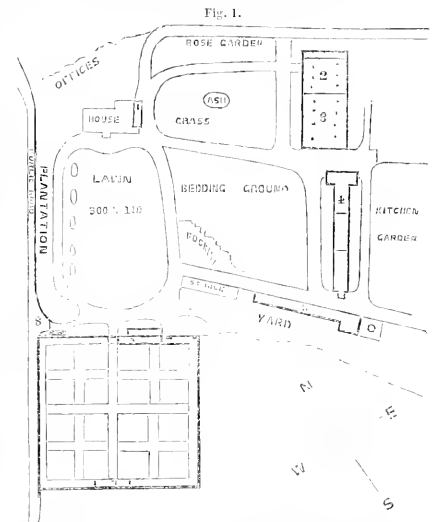

(Continued from page 481.)

ROCKVILLE, BLACKROCK, DUBLIN.

REACHING Dublin by the last train from Kells, and getting recruited at the "Verdun" where the chief substantial articles of the commissariat are supplied from the farm and the large garden of the worthy landlord, who kindly gave us much useful information as to places, &c., we spent the following day at Blackrock and its neighbourhood; which, situated on the south of the Liffey, and east of Dublin, and thus between it and the harbour at Kingstown, is fast becoming to the metropolis, with its squares, and crescents, and villas, what Belgravia and Paddington are to London—with this marked distinction in its favour, that gardening forms as characteristic a feature in its villas as we should expect to find at Dulwich or Norwood. Besides merely glancing at some gardens, and passing through the most of a large nursery near Nutley without seeing any one whatever, we walked through five gardens in the usual way, and were prevented seeing more owing to darkness coming on. In each of these visited we found much that was interesting, though that interest was less associated with the extent of the demesnes than with the different modes employed under different circumstances to make the most of them in a useful or decorative point of view.

The first of these we visited was Rockville, the charming residence of Thomas Bewley, Esq., who, by his wealth, his liberality, his scientific knowledge of gardening and botany, and his admiration for all that is beautiful, and perhaps more especially for all that is rare and attractive in exotic and tropical vegetable lorelines, combined with the advantage of having such a servant as Mr. John O'Brien, who, to a hearty enthusiasm and a next-to-encyclopaedia knowledge of plants, unites great practical experience and cultural skill, has thus made Rockville a place illustrious in the three kingdoms, and brought to it by its fame visitors from the continent of Europe and from among our

cousins across the Atlantic. What is perhaps of more importance still, Mr. Bewley, by the force of his example, has given an impetus to the encouraging of the higher departments of gardening by the gentry of Ireland, and of England too; and shown conclusively that the interest of a place is less dependant on its extent than on the goodness of the management, the peculiar features, and its distinguishing characteristics.

- 1. Conservatory.
- 2. Fern-house and potting-shed at back.
- 3. Fruit-house.
- 4. Orchard-house 138 by 19 feet, potting-house at end.
- 5. Propagating-pit, &c., in yard.
- 6. Boiler and house, heating pits and orchid-house.
- 7. Cold house, north aspect.
- 8. Entrance and gardener's house.

The dotted lines at the outside of the woodcut mark the ground level. The heavy lines represent the section of the Fern-house; the dotted lines within these that of the fruit-house, the floor or bed of which is 2 feet below the ground level, its side-borders being level with the ground outside, and 2 feet above the paths. The Fern-house is 1 foot 6 inches below the level of the fruit-house, the ground falling to the northward. 1. Side-borders 4 feet wide. 2, 2, Paths. 3, Fruit-bed. 4, Boxes planted with Peaches and Nectarines.

On entering the lodge at the south-west corner you perceive before you an open lawn, some 300 feet from north to south, and 140 feet from west to east. A plantation skirts the boundary wall, outside of which is the public road. A drive goes round this lawn, terminating at the mansion, which stands at its north end. Behind you south of this lawn is a square kitchen garden containing about an acre and walled all round, the wall fronting the lawn being here skirted with shrubs. On the south side of this wall there is an excellent vinery, and on the north side of the south wall a cool house of large size for Rhododendrons, keeping soft-wooded plants, retarding plants, and keeping them longer when in bloom. As we do not mean to return to this interesting garden again, we will just mention that the fruit trees and cropping were in excellent order. East of the

south side of this lawn is the stable-yard; the stables and glass-houses beyond being bounded by a wall on the north side. Northward of this is another lawn of about the same size as the first, separated from it by the carriage way, and itself divided into unequal parts, and extending north of the mansion. On the east side of this are situated the large fernery, orchard-house, tropical Orchid-house, and small Fern-houses, making the long leg of the letter L, and the houses already referred to the short leg of the letter reversed, J. That part of the wall where the short leg begins is backed by a mass of rotery and rockwork.

The mansion has two things in a gardening point of view worthy of notice. The first is a glass case of Killarney Fern placed on a table close to the window of a parlour looking to the west; the glass of the window is muffled and flowered elegantly of a white colour, so as to give the requisite amount of shade. The case is 30 inches long, 24 inches deep, and 18 inches wide, and is entirely of glass with the exception of the bottom box, which is about 6 inches deep. The plants looked vigorous and healthy, and were such an ornament as many would greatly prize. As far as we recollect they were thus treated: A layer of the smallest thumb-pots had been placed, bottom upwards, along the bottom of the box; these were covered with a layer of fibry lumpy peat. Over these a layer of peat and moss, in which the roots were planted and covered with moss; then a thorough good watering and time given to drain and settle. Since then they can hardly be said to have been watered; but on moving the glass top moisture is secured by frequent sprinkling and dewing over the surface, which will greatly resemble the dashing of spray and misty vapour from the fall of a stream. A neat finished appearance is given by a row of clean-washed pebbles all round on the top of the moss.

The second thing is a fine curvilinear conservatory or greenhouse, on the east side of the mansion, communicating with one of the principal rooms and provided with a spacious walk with platforms on each side. This house was very gay with *Vallotas*, *Amryllis* of the *Hippeastrum* breed, *Geraniums*, *Balsams*, *Salsvia*, *Oranges*, *Fuchsias*, &c., diversified with the foliage of Ferns and other fine-leaved plants, presenting on the whole a most effective appearance.

On the lawn that here separates the mansion from the fernery and other span-roofed houses, is a fine Weeping Ash, with a circle of gravel beneath it, and underneath that a layer of tar, so that the gravel shall not only be clean and firm but dry for the feet of those who may choose to sit and study in such an arbour. Of course, there is no doubt that the roots of the tree extend far beyond this circle of gravel, as not a drop of rain will penetrate directly through the tar. We found the walks round the lawn were done the same way, and thus not only would a clean and dry but a firm surface be presented to the feet, though using the same single gravel that is so loose in other places before it is well worn down. The tar, of course, will never be seen in such a finished place; the nicety of management consists in having enough to keep the surface firm, and yet so covered as to conceal the firming agency. Mr. O'Brien considers, like your humble servant, the boiling and heating of the tar labour thrown away.

The lawn south of this speaks of openness and freedom, there being only one or two clumps of a good size in the centre, and fair-sized ones a good distance apart round the sides. Each clump was planted with rings of colour, and each, therefore, perfect in itself, as well as contrasting favourably with its neighbours. The very openness is pleasing in any case, but it must be doubly so here, as affording a relief alike to the eye and the mind when next to weighed down and distracted with such a concentration of objects of interest inside the plant-houses. By the sides of these houses are borders separated by a walk from the lawn and partly ribboned. That against the large fernery and orchard-house was thus planted, beginning at the Box, in rows:—1st, *Lobelia speciosa*; 2nd, Variegated *Alyssum*; 3rd, Yellow *Calceolaria*; 4th, Scarlet *Geraniums*; 5th, *Heliotrope*, and a line of *Laurustinus* and standard *Roses* at regular distances. As the front or side glass of the orchard-house comes to the ground, the use of the *Laurustinus*, &c., is to carry the eye from the windows of the mansion or the lawn above the height of the pots inside. The border by the side of the Orchid stove-house, which is of brick and glass and not so high, 135 feet in length, is in rows of blue, white, and red, with a row of mixed dwarfish *Phloxes* at the back, and plants of *Cotoneaster microphylla* to cover the wall. On the other or east side of this stove-house, and concealed by it from the windows and lawn, is

the reserve ground containing low pits and frames, and beds and standing ground for *Chrysanthemums*, *Roses* in pots, *Lilies*, *Salvias*, &c. Close to the rotery and a shaded wall on the south side of the lawn, were a great number of British, Irish, and hardy Ferns, which, no doubt, would soon get a proper home.

From this corner we shall take the houses eastward and northward as they come, merely premising all we can pretend to do, or feel qualified to do, is merely to give a glance at some of the more salient points connected with such a gorgeous collection of plants.

The first house, then, in front of this south boundary-wall to the lawn is 80 feet long, 15 feet wide, and 9 feet in height, and is divided into three or four separate compartments, with a convenient walk down the middle, and supplied amply with bottom and top heat, hotbeds, hand-lights, glass-covered boxes, with tops moveable and tops hinged, and almost every plan that could be thought of for growing and propagating all kinds of tropical plants in the greatest perfection. Such houses would be just suitable for early Vines in pots, or planted out of them, or for early and late Cucumbers and Melons; and we understood they are sometimes used for such purposes, though on our visit they were chiefly employed in propagating new and rare plants, and giving health and vigour to large importations of Orchids. Here, for instance, were the finer *Lycopods* being multiplied by hundreds, and *Pteris tricolor* coming up as thick as the hairs used to be on our head; and there nice plants of the pretty *Lycopodium Wallichii* and *Jamaicensis* imported from Ceylon, and which last has the singular property of becoming almost white at night. Here is a department almost filled with fresh-potted little seedlings of the West Indian Palms. There a collection of the sweet rich-coloured *Anectochilus*, including the rare *Maullii*, lattice plants, the pretty small *Burlingtonia decora*, *Miltonia spectabilis*, and along with *Phalenopsis amabilis*, *grandiflora*, *rosea*, &c., the beautiful *Schilleriana* with the foliage blotched with white stripes and dots.

Then, again, as fresh importations, we found great masses of *Cattleya Mossie*, *crispa*, *amethystina*, *Leopoldii*, &c.; *Saccolabium Blumei*, *Readii*, &c.; the pretty *Iouopsis*, producing its lilac flowers; *Vandas*, of sorts, as *violacea*, *gigantea*, &c.; good plants of *Dendrobium Heyneanum*, and great masses of *Epidendrums*, *Oncidiums*, *Dendrobiums*, &c., fastened to the wood on which they were found growing, or fixed to pieces and blocks of the Calabash tree, which Mr. O'Brien thinks the very best for aerial Orchids, and we presume, also, for fixing across pots, to keep others elevated that are not depending on the moisture of the atmosphere almost entirely.

To give an idea of these importations, Mr. O'Brien counted a few separate plants, such as 20 of *Epidendrum bicoloratum*, 50 of *Saccolabium Blumei* major; 120 of *Oncidium Lanceanum*, 150 of the scarce *Paphinia cristata* (*Maxillaria cristata*), in two varieties, which we were informed was very shy either of the syringe or bright sunlight, and 200 of the *Oncidium papilio* many of which were producing their butterfly flowers, though but two months imported.

Farther eastward on the same wall is a very neat greenhouse, with a double-span or ridge-and-furrow roof, the glass ends of the spans only being seen from the lawn, which would just be the thing for many amateurs, and by a similar plan any space may be enclosed without having a high roof. This neat affair is 30 feet long, 20 feet wide, 11 feet high at the apex of the span, and brick walls ends and sides 5 feet in height. Ventilation in abundance is given by glazed shutters in the ends of the spans, and by openings in the side walls. The roof is thus all fixed, and the sash-bars are neatly formed of iron, and screwed to the ridge and wall plates, which gives a much lighter appearance than wood would have done. The roof is of Hartley's Patent. The internal arrangements for the plants are exceedingly simple and neat:—A broad level platform all round, about 3 feet or more from the ground, and a walk of 3 feet or so between that and the centre platform or table which is from 7 feet to 8 feet wide. These platforms are supported by neat east-iron columns, and are themselves formed of pine wood well pitched, and then covered with a layer of fine-washed sea gravel for the plants to stand upon. The floor beneath the platforms is also thus covered, though but little is seen of it, as a wide board fastened on the sides not only gives a shallow rim as it were to the beds, but the lower part being scolloped or swept into elliptic curves, and then painted dark green with golden bands of colour gives to the whole a very tasty, finished appearance. The house

was filled with some of the finer Azaleas, Pimeleas, Epacris, &c., of which we can only say they did no discredit to the neat house. Of a few softwooded things we noticed *Streptocarpus biflorus*, *Tydea lopicum*, a fine dark purple, and a seedling *Genera*, a cross between splendens and cinnabarinum, with fine handsome marked foliage, and a strong branching spike of brilliant flowers, with wide open throats, showing the inside dotted with beautiful spots.

Having thus passed the short reversed leg of the L, we turn northwards, taking the various houses on our way. In the range of opaque buildings already referred to, though not quite sure of their position, are two small houses, 16 feet long, 7 feet wide, and 7 feet in height. On entering the first, but for the windows of coloured glass you might take it to be a dark moist care of tupa and conglomerate, and filled chiefly with the *Clare* or *Andrewsii* variety of the *Trichomanes radicans*, growing and flourishing nicely. The other house is about the same size, and finished in the more ordinary rockwork style, and planted with the true *Killarney Fern*, *Trichomanes radicans*. The light to this house is furnished by a skylight in the end of the roof facing the north, by which also the necessary air is given.

We now come to the large *Orchid* and *tropical stove-house*, which is 135 feet long, 19½ feet wide, 14 feet in height to the apex of the span, and 4½ feet in height at the sides. The ventilation at the sides is chiefly given by openings in the wall furnished with caps or slides, the air admitted thus being brought into contact with the heated pipes before being diffused among the plants. The air at the top is given by openings between a double ridge-board; the ventilating-board being fixed in a groove on each side, and pulled along by a rope and pulley, much on the same principle as the ventilating-board in the new houses of Mr. Nivens at Drumcondra. The internal arrangements are

a broad shelf along the sides and a platform in the centre, consisting of a broad shelf on each side and a raised one in the centre. These shelves and platforms are supported at the sides by neat iron columns; and the platforms are, whether wood or stout slate, covered with clean-washed small sea-shingle. This house is divided into three compartments, besides the entrance corridor of 9 feet by 8 feet by 7 feet, which has a case of *Killarney Fern* on one side and a similar case of *Andrewsii* on the other, and a large book in which the names of visitors are enrolled. The first division is 40 feet, the second 30 feet, and the third 60 feet in length. The first division is chiefly devoted to the hardier and South American *Orchids*, and to others when in bloom. All seemed in the highest possible health. Of these in bloom we noticed a noble plant of *Odontoglossum grande*, with about forty expanded flowers, and a good specimen of *rostratum*. Also in bloom were fine plants of various *Phalenopsis*; *Laelis elegans*; *Paphinia cristata*, two varieties; *Oncidium Lancanum*, *papilio*, and several others; *Erides suavisimum*; *Cypripedium Fairrieanum*, with fine striped foliage, and *caudatum*, *Lown*, &c.; *Zygopetalum*, &c.; also fine-flowering plants of the white *Eucharis amabilis*. The house was also rendered attractive with masses of *Cattleyas*, *Oncidiums*, &c., suspended masses of *Dendrobies*, *Erides*, *Stanhopes*, &c.; and the platforms gay with a great variety of the fine-leaved *Begonias*, *Caladiums*, including *Belymanii*, mixed with the finer-fronded *Ferns*, as *Gleichenia dichotoma* and various *Adiantums*, &c. Not the least charm, however, was the roof. Over the whole, on longitudinal wires about a foot apart, were trained alternately the beautiful crimson *Passiflora kermsina*, and the rich blue lilac *Passiflora quadrangularis*, or the *Granadilla*. These would make a beautiful contrast, and were thin enough to allow of plenty of light. There was not much contrast in the flowers on our visit, as there were few flowers on the *Granadilla*, but such a mass of fruit we never witnessed before. They were set as regularly along the wires as if a rule and compass had been used for them. We presume considerable care must have been taken to fertilise them. If good nourishment were given to the plant, the worthy owner would have it in his power to give a treat to those lovers of the good things who look upon a Melon as not fit to be compared with the *Granadilla*.

The second division is devoted to *East Indian Orchids*, and those requiring a high temperature. Here in flower we noticed the *Ionopsis paniculata*, the chaste *Calanthe vestita*, several

Phalanopsis, a noble plant of *Uropedium Lindenii*, also fine masses, though not in bloom, of the *Peristeria elata*, *Cattleya amethystina*, *Leopoldii*, &c., *Erides crispum*, *Warnerii*, &c., *Saeocolobium*, as *Readii*, &c., with large masses of *Dendrobies*, *Oncidiums*, *Epidendrums*, *Barkerias*, *Laelias*, &c., depending from the roof in baskets, or fastened to the *Calabash tree*. Here, also, we noticed some nice plants of the old but bright scarlet *Musa coccinea* opening its blooms, and a noble plant of *Musa Cavendishii*, planted eight months from the sucker, and now having leaves 66 inches in length, and 31 inches in width, the height of the plant being 8 feet. Interesting and striking as all these and many more are, there is one feature still that for gorgeous and picturesque effect throws them all into the shade. On opening the door to this compartment, but for the firm path beneath your feet, and a peep at the glass here and there, you might imagine that by the magic spell of an enchanter you had been carried in a mesmeric sleep over continent and ocean, only to open your eyes to gaze upon a forest tropical scene, unequalled for wild luxuriant loveliness and beauty. This is all due to the *Cissus discolor* being trained along the roof, not in stiff lines and bands, but allowed to depend in long streaming shoots all over the house, wherever room could be found for them. This regulated wild grandeur not only gave the house a natural appearance contrasting with the greater degree of trimness in the compartments on each side of it, but from good nourishment and a proper amount of light, the leaves were not only of good size but exceedingly rich in their shaded marbled colourings. We presume the plants will be considerably cut back or thinned in winter, or rather in autumn, to give more light, but we forgot to make inquiries on that subject. However, there is no doubt that it will stand the knife freely, and produce plenty of fresh shoots, though pretty freely spurred back.

The third compartment is the largest, and besides noble specimens of *Orchids*, has a fine collection of good-foliaged plants, *Ferns*, and *Mosses*. The roof, as in the first compartment, is supplied with longitudinal wires, and on these were strong shoots of the grand old climber *Impomea Horsfallii* producing masses of crimson flowers. We forget whether *Allamandas* were at all trained to the wires; but if not, several plants presented not only a fine contrast in colour to the *Ipomea*, but the trimness of the latter was softened down by the somewhat natural dangling and festooning of the former. Among singular and fine-foliaged plants we noticed good specimens of varieties of the *Pitcher-plants*; a splendid specimen of the *Theophrasta imperialis*, well named imperial, and worthy of commemorating the great botanist of antiquity; a noble plant of *Cyanophyllum magnificum*, with its magnificent foliage; large beautiful plants of *Croton pictum*, and others; *Drezenas*, of various kinds; the new *Coleus Verschaffeltii*; a rich assortment of *Caladiums*, containing almost every variety out, including *pectinatum*, with its rich veins in the centre, and many with foliage as large as luxuriant *Cauliflowers*; and among *Alocasias*, the pretty *Alocasia variegata*, and the bronzy purple metal-leaved *Alocasia metallica*, supposed to be the best plant in the three kingdoms.

Among *Ferns* we noticed some fine plants of the angular *Platyerium*, as *grande*, *sternmaria*, *biforme*, &c., clinging to blocks or masses of tufa; noble plants of the *Adiantums*, as *trapeziforme*, *macrophyllum*, *triangulare*, *temerum*, *brasilense*, and many others. Among twining and haunting *Lycopodiums* was the new *L. polystichum*. Of *Gymnogrammas*, beginning with *chrysophylla*, there were fine plants of all the best kinds; but, perhaps, as conspicuous as any were fine plants of *Davallia aculeata*, some 4 feet in diameter, and as much in height, with fine prickly fronds; and equally fine, noble plants of *Thyrsopteris elegans*, and *Drynaria coronaria*; whilst by way of contrast, in sheltered nooks we find such beauties as *Trichomanes anceps*, *exsiccum*, *floribundum*, *rigidum*, *elegans*, &c., and such *Hymenophyllums* as *scabrum* and *ciliatum*; whilst clinging to a piece of mossy conglomerate is the interesting *Arthrobotrys articulata*, producing its fronds only on one side of the stem, and looking to the passer-by as much like a Moss as a Fern.

Then as to *Mosses* or *Lycopods* it would be endless to enumerate them. From being out of practice there were many we had never before seen, or even heard of. The newer kinds would soon be fine plants, and all the older varieties were from 24 inches to 30 inches, and 36 inches across, and covering and concealing the pans and boxes with their rich verdure. In walking along noble specimens caught our eye of *Warzewiczii*, *rubricaulis*, *Wallichii*, *jamaciense*, *inequalifolium*, *Lobbii*. The two latter

some 3 feet in diameter, and more in height. A descriptive list of *Lycopods*, with synonyms up to the present time, would be very interesting to those who love them, though they have no chance of growing them.

Near the north end of this compartment is a basin or fountain; the centre stalk being graced with Ferns and Mosses, *Echinanthus* in baskets, and drooping Ferns, as the beautiful *Goniophlebium Plusvardii*, had fronds from the roof reaching almost to the ground. The north end of this division is a solid wall, and in front of it there was a wall built of soils of heath mould, &c., over which were creeping pieces of *Cissus discolor* and other trailers; whilst many little Ferns were growing and seeding themselves freely. A part of the opaque roof was getting covered with *Ficus stipulacea* clinging firmly to it. In the turf wall itself many vaults and crannies, caves and recesses were formed, where the finer *Trichomanes* and *Hymenophyllums* already mentioned were finding suitable homes; and in a snug corner in a case was nestled another beautiful assortment of *Anacrotichium*.

At this end of the house is a neat comfortable room or shed, so that every plant in pot, or basket, or log, may be easily examined without being taken out of doors or making a mess in the house. Whilst enjoying ourselves here, and looking into the orchard-house, where we felt ourselves more at home, and where too our readers may feel a sort of relief after being kept so long amidst such tropical grandeur, we would desire to mention a few facts. The whole of the houses we have passed through are heated, and to any temperature desirable, by one of Weeks' boilers, which answers admirably. Another small boiler is used for the orchard-house and Fern-house. We did not notice a single unhealthy plant in the houses: if such there were, they must have had a hospital for themselves out of the way. Neither did we notice the sign of bug, scale, thrips, or any other vermin; so that if there were any such things they wisely kept out of sight. Again, there was a peculiar neatness and neatness about the finish of all Orchids elevated in pots, or even suspended in baskets, the surface being so smooth and firm that there was scarcely a chance for a woodlouse or a cockroach finding a hole in which to burrow. Mr. O'Brien is so liberal-hearted, that he venture to make known the secret—a valuable one to Orchid-growers. It is this: Sphagnum is chopped very fine when dry; it is then moistened, placed all over as a covering about half an inch thick, watered, pressed firm by means of any suitable substance, and afterwards it keeps as firm and smooth almost as metal cast in a mould. And, lastly, large earthenware pots, No. 1 size, but without any holes at bottom, are set at intervals along the sides of the paths below the platforms, and kept filled with soft water; so that, besides giving out much vapour to the house, there is suitable, soft, exposed, warm water always ready for watering, syringing, or dipping. The practice—one of those little matters that tell for ultimate success—has several times been recommended by our friend Mr. Appleby.

R. FISH.

(To be continued.)

ROYAL HORTICULTURAL SOCIETY.

The Council have appointed an *Implement Committee*. Its members are Mr. E. Easton, Mr. J. Fleming, Mr. B. Gibbs, Sir F. Paxton, and Mr. J. Veitch, jun., with Colonel Chaloners as Chairman. The objects the Society have in view are the improvement of garden tools, heating apparatus, pottery, ornamental work, and, in short, of every article connected with the practice of gardening.

Applications for schedules of prizes, &c., must be made to Mr. Eyles, Superintendent of the Garden, Kensington Gore.

WORK FOR THE WEEK.

KITCHEN GARDEN.

Sowing of all kinds of seeds should be proceeded with as speedily as the state of the ground will permit. *Asparagus*, top-dress the beds, taking care not to injure the plants with the rake or fork. A little *Celery* or *Lettuce* seed may be sown over the beds, and new plantations made. *Beet*, this may be sown in drills a foot apart. *Broccoli*, make a sowing of Grange's Early White. *Cabbage*, plant out the autumn-sown, clean up the leaves, and weed the beds left for Coleworts. *Capsicums*, sow on a hotbed. *Cauliflowers*, stir the soil round those under hand-glasses, and earth them up. Water at the roots with

manure water. *Peas*, continue sowing for succession crops; earth-up and stick those already up as they require it. *Potatoes*, plant for a principal early crop while the ground continues in good working order. Sow, if not already done, Turnips, Carrots, Leeks, Onions, Parsley, small salad, and pot herbs.

FLOWER GARDEN.

The preparation of flower-beds should not be delayed until the day of planting. Continue to prune *Roses*. *Dahlias* for the pleasure ground may be put in action and propagated. Roll walks and destroy weeds. The soil around *Pinks*, *Heartsease*, and other florists' flowers should be examined; and, if loosened by the frost, it should be regulated and gently pressed around them. Protect the foliage of bulbous roots whenever there is an appearance of a sharp frost. Proceed with removing and planting all sorts of evergreen shrubs, and let all improvements in this department be completed as speedily as possible. Sow seeds of tender annuals in pots, and of hardy annuals in the open ground when the weather is fine.

FRUIT GARDEN.

Take care that all newly-planted trees are securely staked and mulched, and that the blossoms of the early kinds are protected in due time. Planting, pruning, and nailing should now be finished as soon as possible: these operations cannot be finished a minute too soon. The sap having now commenced its ascending course, broken-off flower-buds and injured shoots will be the certain consequence of neglect and delay.

STOVE.

Cuttings of all free-growing soft-wooded plants, such as the different showy varieties of *Justicia*, *Begonia*, *Aphelandra*, *Poinsettia*, &c., will now strike readily in a brick bottom heat; they will make useful plants for autumn and winter blooming. Some of the *Orchids* will probably require shading; at all events see that the material is ready for use, but do without it as long as possible; and with a little foresight in removing plants likely to be injured to shady situations it will not be necessary, at least in most cases, to apply it just yet. Encourage growth by syringing with clean water all over the leaves, and every part of the house, and filling it with vapour. Admit air on all favourable opportunities, but close up early to secure solar heat.

GREENHOUSE AND CONSERVATORY.

Top-dress and shift all plants that require to be so treated. Remove into the hothouse *Camellias* that have flowered, for the purpose of encouraging the growth of the young shoots and flower-buds. Train and tie-up climbing plants to pillars and trellises. The recently potted plants to be rather sparingly supplied with water until they have made fresh roots; keep them close and syringe frequently, so as to maintain a rather humid atmosphere. Annuals intended to decorate these houses should now be sown in heat, such as *Balsams*, *Cockscombs*, *Browallias*, *Martynias*, &c. As soon as they have expanded their seed-leaves pot them off into three-inch pots, and keep them in a warm frame or pit near the glass.

PITS AND FRAMES.

A very busy season has commenced in this department. Every spare light should be put to use as soon as frame *Cauliflowers*, *Lettuces*, *Radishes*, and forced *Asparagus*, &c., come off. Fresh hotbeds to be made in succession, and linings to be attended to. Sow *Auricula*, *Polyanthus*, *Ranunculus*, and *Pansy* seeds. Annual plants, such as *Mignonette*, *Asters*, *Ten-week Stocks*, &c., to be sown on a slight hotbed, and brought forward in pits to succeed the plants raised in the autumn, and that had been kept in pits or frames during winter. *Auriculas* will be fast progressing and must be looked to that they may meet with no check in the development of their flowers. All weak and secondary trusses of bloom to be removed as soon as they can be detected, and it is also important that they may be protected from frost and supplied with a sufficiency of water; at the same time they require to be kept cool, and to have all the air that can be given to them when the weather is at all mild. As the lower-stems advance they should be protected from sudden sunbursts by shading. Encourage the growth of *Potatoes*, *Radishes*, *Carrots*, and other frame crops by surface-stirring and applying tepid water. Prepare a slight hotbed for turning out under hoops *Potatoes* already sprouted in pots or boxes. Admit abundance of air on all favourable opportunities, and continue protection at night as long as there is any appearance of frost. Top-dress *Auriculas*, *Polyanthuses*, *Carnations*, &c. Attend to the young stock which is intended for bedding-out, and go on

propagating *Calceolarias*, *Verbenas*, *Heliotropes*, *Petunias*, and other plants for bedding-out as they can be spared.

FORCING-PIT.

Continue to remove forced flowers the moment a bud begins to open. Stop the barren shoots of Perpetual Roses; these bear the blossom-buds. Take care that no plants suffer for want of water. This pit as well as the houses and frames should be examined daily. Increase atmospheric moisture considerably, and syringe on most afternoons. All American plants require large quantities of water when forced. Introduce dry bulbs of sorts to succeed *Gloxinias* and *Achimenes*. W. KEANE.

DOINGS OF THE LAST WEEK.

GENERAL ROUTINE.

MUCH the same as last week. Owing to dripping weather could do but little on the open ground. Trapped mice and birds from making depredations on Peas. Took out those sown in a house to harden before transplanting. Planted Potatoes when dry. Thinned Cauliflowers under glasses. Repotted Cucumbers, as we have still no room to plant out; though large plants, we shall most likely keep some in pots. Took up some beds of Celery to have the ground turned over, laying it in earth as thick as it would stand. Pricked out Lettuces, Celery in pans, &c.

FRUIT GARDEN.

Potted young Melon plants. Cut down young Vines that had been kept in a cool place in eight-inch pots, and painted the cut to prevent bleeding. Will set them in a little heat so as to come on slowly and be ready for larger pots, not yet being decided whether to grow them as rods or as bushes. Had intended them for the roof of a late-house, but as I cannot run a pipe or flue through it, find that would be of no use, as I could not keep the bunches there after frost set in. Having covered two pieces of a south wall with glass, was anxious to give as much heat to one as would keep out much frost, so that it would come before the other, otherwise if all goes well, there would be far too many Peaches at one time. We could easily bring one in before the other, by regulating air-giving, &c.; but then if too forward, and we had sharp frost in the end of March, the forward ones would suffer. To gain my object so far, I will put in the iron stove that did such good service in the conservatory when the boiler gave way at Christmas, a twelvemonth ago, and by sinking it a little near the front I should be able to take the pipe out at the ventilator at the bottom of the wall at the back, without interfering either with roof or wall. The trees against the wall after being well daubed, are now fastened to it, and, as the handiest and cheapest mode, are tied to studs formed of cast-metal nails, driven $\frac{1}{2}$ inches from nail to nail, into every alternate line of bricks, so that the studs from the centre of one to the centre of the other, will be nearly 6 inches apart one way, and 5 inches the other. With such an arrangement there is no difficulty in training fan-shaped, and thus the studs will remain as fixtures, and holes in the wall, and the dirt and harbour of insects by shreds be avoided. To prevent the studs rusting, they were daubed with thin white paint by a small brush a day before tying. The front of the lean-to house will have two or three rows of plants in pots at present, most likely to be planted out when somewhat established in fruiting habits, and notwithstanding the strictures of our good friend, Mr. Robson, I expect that even this season they will yield a return for the labour. Some very small ones did well last season, and some Peaches and Apricots that we bought as maidens this time last year, are now very fairly supplied with bloom-buds. We have been forced to smoke the Peach-house at length, as a black-looking fly has made its appearance in a few places, and what is worse, the tobacco smoke seems to have done little more than make them a little sickly. We must have recourse to the Weaver remedy, and a dust of hellebore or snuff if they do not take their leave of us. Twisted some long rods of Vines to cause them to break equally, and syringed those in a later house where the buds were swelling.

FLOWER DEPARTMENT.

Put in cuttings of Honeysuckles, variegated Ivies, &c., under bell-glasses out of doors; also a good number of *Rose cuttings* of the China, Tea, and Perpetual kinds, cutting them in rather small pieces right across at a bud at the base, and leaving the bud there, and one or two more, and leaves forming, were

docted in so as to leave the centre chiefly. Put them in well-drained pots with a couple of inches of sand over some rough material below, and plunged them in a mild bottom heat from tree leaves, keeping rather close during the day and giving air at night. When the bases swell or callus, will give a little more heat to hasten rooting, whilst air is thus kept on at night. Potted-off those struck in autumn, and gave them a close place to start them afresh. Put in cuttings of bedding *Geraniums*, *Dahlias*, &c., keeping them at such a distance from the glass as to need little or no shading, giving them thus diffused instead of shaded light. Potted-off *Geraniums* for bedding where they stand too thick in boxes as room could be had for them. Potted *Chrysanthemums* and put them under glass just to establish themselves before being turned out. Sowed *Lobelia seed*, *Tomatoes*, *Capsicums*, &c. Those who have plenty of room might have done so earlier, but we like to keep them growing after they are up. Regulated conservatory, and festooned up the stove by regulating climbers; clearing dead fronds from Ferns, and setting plants gently going that had been resting during the winter. Removed *Poinsettias*, and put them beneath the stage in a cool vinery to harden and dry before cutting them down. Potted *Begonias*. Removed stove-pots of *Verbenas*, rather stunted from being cut down pretty freely, out of their pots into a bed of rich earth, with a frame over them, and a little bottom heat beneath them, which will cause them to break more quickly and strongly, and give us the pots at liberty as well. Turned tenderer *Geraniums*, as *Alma*, out of single pots into boxes, to stand at first in the pathway of the greenhouse, and then be hardened-off. Turned out others of the *Scarlet kinds* into earthen pits, to be covered at first with spare sashes laid on back and front. Commenced planting out *Calceolarias* in turf pits, some 4 inches apart, to be protected by a slip of calico about 5 feet wide. This calico, in lengths about 50 feet, is fastened by tape and tacks at each end to poles about 8 feet long, and from $1\frac{1}{2}$ inch to 2 inches in diameter. On these the calico is rolled when not wanted. Beginning at one end the pole is fastened securely, having previously rolled the piece on the other pole, which is then unrolled as we plant. A few stakes are laid across, such as are used for *Dahlias* and *Hollyhocks*, to prevent sagging, and then every 5 feet or 6 feet a string is sewn on the calico opposite each other back and front, and these, fastened to little stakes in the earth or turf bank, keep the calico as tight as an open umbrella. In very severe weather branches, or clean litter, are thrown over. This is the simplest and best, and, as respects labour, the most economical plan we have tried. We have sometimes tightened the calico thus, and never removed to water, &c., until a few days before planting-out time. We use cheap unbleached; it soon gets white enough with sun and rains.—R. F.

TRADE LISTS RECEIVED.

New Roses, Gladioli, Hollyhocks, Pelargoniums, Fuchsias, &c. by William Paul, Waltham Cross, N.—This is Mr. Wm. Paul's catalogue of novelties in the way of what are called soft-wooded and bedding plants, as well as of *Roses*, *Gladioli*, &c., and it will be found well worth perusal.

A Descriptive Catalogue of Chrysanthemums, Dahlias, Fuchsias, Verbenas, Geraniums, &c., by Wm. Holmes, Hockney, N.E.—Mr. Holmes has here given us the cream of the different sorts of flowers contained in the catalogue, and it will, therefore, be a very useful assistant to those who wish to make selections, and who may safely rely on Mr. Holmes' excellent judgment on such matters.

A Descriptive Catalogue of English and Foreign Novelties comprising Dahlias, Peonies, Phloxes, Fuchsias, Chrysanthemums, &c., by John Salter, Hamersmith, W.—In this catalogue will be found many subjects of interest, and which are offered for sale for the first time in this country.

Wheeler & Son's Little Book or Selected Seed List for 1862, Gloucester.—Besides a very nicely-selected catalogue of garden and flower-seeds, which is interspersed with many useful observations, we have here a treatise on the Grasses of the farm illustrated with well-executed woodcuts.

Sutton's Farm Seed List, Reading, 1862.—In this will be found every article in the way of seeds necessary for stocking a farm.

Catalogue of Cuttings Grown for Sale at the Nurseries, Dursley, Gloucestershire, by John Morse.—In this catalogue every description of soft-wooded and bedding-plants is offered in the form of cuttings.

TO CORRESPONDENTS.

We request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

We cannot reply privately to any communication unless under very special circumstances.

BIRCH TREES BLEEDING (J. C.).—To stop the outflow of sap, or bleedings from the wounds where large branches have been lopped is very difficult, and you will probably not cause it to cease entirely until the leaves are expanding, when the outflow will leave off naturally. We believe that fresh young saplings, abundantly supplied with the wounds serves to reduce the bleeding, and that the best remedy is to cut the trees in winter. You have the consolation, however, even if the bleeding continues, in knowing that it will not perceptibly weaken your trees. Birch trees that have been tapped, and gallons of sap taken from them, vegetate seemingly as vigorously as those which have not been tapped.

WIREWORMS (An Amateur).—The light red worms you mention were certainly not wireworms, for these are yellowish-white with brown heads. Those in the Vine-border probably were wireworms. There is no application that will kill them that would not kill the plants also. The only resource is to trap them by burying slices of Potatoes, Carrots, &c., in the soil, to examine the slices and destroy the wireworms that are sticking to them. Lime water does not kill them.

FLOWER GARDEN PLANS (J. V. Aucton).—Your sketch circular plan with those circles on each side is planned very well indeed, and the plan on the oval paper is such as badly done as you could make it. The corner figures in such a plan as 1 and 2 should be planted in match pairs, and a variegated plant as in 2, is inadmissible in an outside or end corner according to the fashion of the day. 4, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33, 34, 35, 36, 37, 38, 39, 40, 41, 42, 43, 44, 45, 46, 47, 48, 49, 50, 51, 52, 53, 54, 55, 56, 57, 58, 59, 60, 61, 62, 63, 64, 65, 66, 67, 68, 69, 70, 71, 72, 73, 74, 75, 76, 77, 78, 79, 80, 81, 82, 83, 84, 85, 86, 87, 88, 89, 90, 91, 92, 93, 94, 95, 96, 97, 98, 99, 100, 101, 102, 103, 104, 105, 106, 107, 108, 109, 110, 111, 112, 113, 114, 115, 116, 117, 118, 119, 120, 121, 122, 123, 124, 125, 126, 127, 128, 129, 130, 131, 132, 133, 134, 135, 136, 137, 138, 139, 140, 141, 142, 143, 144, 145, 146, 147, 148, 149, 150, 151, 152, 153, 154, 155, 156, 157, 158, 159, 160, 161, 162, 163, 164, 165, 166, 167, 168, 169, 170, 171, 172, 173, 174, 175, 176, 177, 178, 179, 180, 181, 182, 183, 184, 185, 186, 187, 188, 189, 190, 191, 192, 193, 194, 195, 196, 197, 198, 199, 200, 201, 202, 203, 204, 205, 206, 207, 208, 209, 210, 211, 212, 213, 214, 215, 216, 217, 218, 219, 220, 221, 222, 223, 224, 225, 226, 227, 228, 229, 230, 231, 232, 233, 234, 235, 236, 237, 238, 239, 240, 241, 242, 243, 244, 245, 246, 247, 248, 249, 250, 251, 252, 253, 254, 255, 256, 257, 258, 259, 260, 261, 262, 263, 264, 265, 266, 267, 268, 269, 270, 271, 272, 273, 274, 275, 276, 277, 278, 279, 280, 281, 282, 283, 284, 285, 286, 287, 288, 289, 290, 291, 292, 293, 294, 295, 296, 297, 298, 299, 300, 301, 302, 303, 304, 305, 306, 307, 308, 309, 310, 311, 312, 313, 314, 315, 316, 317, 318, 319, 320, 321, 322, 323, 324, 325, 326, 327, 328, 329, 330, 331, 332, 333, 334, 335, 336, 337, 338, 339, 340, 341, 342, 343, 344, 345, 346, 347, 348, 349, 350, 351, 352, 353, 354, 355, 356, 357, 358, 359, 360, 361, 362, 363, 364, 365, 366, 367, 368, 369, 370, 371, 372, 373, 374, 375, 376, 377, 378, 379, 380, 381, 382, 383, 384, 385, 386, 387, 388, 389, 390, 391, 392, 393, 394, 395, 396, 397, 398, 399, 400, 401, 402, 403, 404, 405, 406, 407, 408, 409, 410, 411, 412, 413, 414, 415, 416, 417, 418, 419, 420, 421, 422, 423, 424, 425, 426, 427, 428, 429, 430, 431, 432, 433, 434, 435, 436, 437, 438, 439, 440, 441, 442, 443, 444, 445, 446, 447, 448, 449, 450, 451, 452, 453, 454, 455, 456, 457, 458, 459, 460, 461, 462, 463, 464, 465, 466, 467, 468, 469, 470, 471, 472, 473, 474, 475, 476, 477, 478, 479, 480, 481, 482, 483, 484, 485, 486, 487, 488, 489, 490, 491, 492, 493, 494, 495, 496, 497, 498, 499, 500, 501, 502, 503, 504, 505, 506, 507, 508, 509, 510, 511, 512, 513, 514, 515, 516, 517, 518, 519, 520, 521, 522, 523, 524, 525, 526, 527, 528, 529, 530, 531, 532, 533, 534, 535, 536, 537, 538, 539, 540, 541, 542, 543, 544, 545, 546, 547, 548, 549, 550, 551, 552, 553, 554, 555, 556, 557, 558, 559, 560, 561, 562, 563, 564, 565, 566, 567, 568, 569, 570, 571, 572, 573, 574, 575, 576, 577, 578, 579, 580, 581, 582, 583, 584, 585, 586, 587, 588, 589, 590, 591, 592, 593, 594, 595, 596, 597, 598, 599, 600, 601, 602, 603, 604, 605, 606, 607, 608, 609, 610, 611, 612, 613, 614, 615, 616, 617, 618, 619, 620, 621, 622, 623, 624, 625, 626, 627, 628, 629, 630, 631, 632, 633, 634, 635, 636, 637, 638, 639, 640, 641, 642, 643, 644, 645, 646, 647, 648, 649, 650, 651, 652, 653, 654, 655, 656, 657, 658, 659, 660, 661, 662, 663, 664, 665, 666, 667, 668, 669, 670, 671, 672, 673, 674, 675, 676, 677, 678, 679, 680, 681, 682, 683, 684, 685, 686, 687, 688, 689, 690, 691, 692, 693, 694, 695, 696, 697, 698, 699, 700, 701, 702, 703, 704, 705, 706, 707, 708, 709, 710, 711, 712, 713, 714, 715, 716, 717, 718, 719, 720, 721, 722, 723, 724, 725, 726, 727, 728, 729, 730, 731, 732, 733, 734, 735, 736, 737, 738, 739, 740, 741, 742, 743, 744, 745, 746, 747, 748, 749, 750, 751, 752, 753, 754, 755, 756, 757, 758, 759, 760, 761, 762, 763, 764, 765, 766, 767, 768, 769, 770, 771, 772, 773, 774, 775, 776, 777, 778, 779, 780, 781, 782, 783, 784, 785, 786, 787, 788, 789, 790, 791, 792, 793, 794, 795, 796, 797, 798, 799, 800, 801, 802, 803, 804, 805, 806, 807, 808, 809, 810, 811, 812, 813, 814, 815, 816, 817, 818, 819, 820, 821, 822, 823, 824, 825, 826, 827, 828, 829, 830, 831, 832, 833, 834, 835, 836, 837, 838, 839, 840, 841, 842, 843, 844, 845, 846, 847, 848, 849, 850, 851, 852, 853, 854, 855, 856, 857, 858, 859, 860, 861, 862, 863, 864, 865, 866, 867, 868, 869, 870, 871, 872, 873, 874, 875, 876, 877, 878, 879, 880, 881, 882, 883, 884, 885, 886, 887, 888, 889, 890, 891, 892, 893, 894, 895, 896, 897, 898, 899, 900, 901, 902, 903, 904, 905, 906, 907, 908, 909, 910, 911, 912, 913, 914, 915, 916, 917, 918, 919, 920, 921, 922, 923, 924, 925, 926, 927, 928, 929, 930, 931, 932, 933, 934, 935, 936, 937, 938, 939, 940, 941, 942, 943, 944, 945, 946, 947, 948, 949, 950, 951, 952, 953, 954, 955, 956, 957, 958, 959, 960, 961, 962, 963, 964, 965, 966, 967, 968, 969, 970, 971, 972, 973, 974, 975, 976, 977, 978, 979, 980, 981, 982, 983, 984, 985, 986, 987, 988, 989, 990, 991, 992, 993, 994, 995, 996, 997, 998, 999, 1000.

HARBY EVERGREEN FOR THE PILLARS OF A PORTICO (T. P.).—Evergreen hardy and showy climbers are just as rare as winter-flowering Perpetuals, Roses—there is not one of either. The *Lonicera flexosa*, or Japan Honey-suckle, and the *Sempervivum running* Roses, are the nearest to what you want, and the good old *Filix Perpetuelle* and *Princess Marie* Roses are still two as good as any of the kind.

SELECT FRUITS (G. J. N.).—You ask a question which it is very difficult to answer, and you do not say at what seasons you require the fruit to be ready; however, we will do the best we can for you. *Apples*—Ribston Pippin and Bedfordshire Foundling. *Pears*—Marie Louise and Cattilac. *Vines*—Moorpark and Musch-musch. *Peach*—Gracie Mignonne. *Nectarines*—Erlage. *Plums*—Grey Gage, ruffled, red, and blue. *Goose's Golden* Red. *Red Plum*—Le Montfort, Victoria, and Diamond. *Goose's Golden* Red Antwerp and Fastolf. *Strawberry*—British Queen and Elton.

TOBACCOLENS WEED (Clericus).—It is not right to expect that we can detect a plant from a fragment of root; but it happens that we think we recognize it as one of the *Equisetums*, or Horsetails. We could recognize it as a fragment of stem and leaves were sent. The whole genus are natives of soils in which there is an excess of moisture, and the only radical remedy is to drain.

INJURY FROM TOBACCO FUMIGATION (T. P.).—Either there was something prejudicial in the tobacco, too strong a dose was given—that is, too much at once smoking, or the tobacco was too hot, which we think was very likely the cause. It is always safest to smoke several times a day, and not so much at once: a patent fumigator will insure the smoke being presented cool. When a pot of any kind is used, a covering of damp moss is indispensable to cool the smoke as it rises. There is nothing in the pieces of wood and oak; two or three live cinders, and a bit of paper put over them, and then the tobacco is as good as anything. Are you sure the vessel used was all right? Every gardener gets such lessons, as the hard knocks of experience. When such results are repeated afterwards, then there is blame for carelessness.

DATURA ARBOREA CULTURE (M. F.).—We should have liked you to have stated the length of your shoots, because from the large and drooping character of the flowers, *Datura arborea*, and *Brunsmiana suaveolens* and candida being the same thing, they always look best on a plant from 3 feet to 6 feet or more in height. According to your room, therefore, we would only remove a little of the stem and leaves every second time you cut up the shoots. After doing that, they will generally shoot from the top of the stems, and we would remove all except three or four at the top of each stem. The plant would be more elegant if grown to one stem; then take the ball of the plant, disengage the roots, shake out a good portion of the soil, and re-plant in a size larger pot, using strong, rich loam. The plant will thrive admirably in the greenhouse, and so it will planted out of doors after June, and taken up in October. If the shoots were well-ripened last autumn, you will have plenty of flowers on the shoots of this year. Next season prune pretty well back, and treat in the same manner.

OXALIS CRISTATA CULTURE (Oralix).—The plant generally flowers in the autumn about the end of August. Then allow the plants to naturally take up the roots, and treat as *Dahlia*s or *Potatoes* in winter, placing them in dry sand. Then pot a few in March or April in smallish pots, giving a strong water in a five-inch pot, and the curbing of the pot will cause flowers to appear in June. The rest you may plant in well-pulverized ground out of doors, and you may eat the young stems as salad, or use the tubers in winter as *Potatoes*. In damp seasons it is apt to grow too much to leaf out of doors to flower well.

FLOWER-GARDEN PLANS (J. V. Aucton).—Your one half of the coloured geometric garden, with the *Primula*—feather-like beds, is exceedingly well planned. Of course, in the other half—feather-like beds, in various colours cross-cornerwise; and, of course also, there is a match for the bed 4.

STABLE DRAINAGE (E. M. M.).—The drainage, if it has no other diluting than that from the legs of the horses &c. or three a-week, had better be mixed with twice its weight of water before being applied to the borders, and even then ought not to touch the foliage.

BEDDING GERANIUM (J. T. C. Dublin).—Your Geranium is the Rose Unique. A very different kind is called *Picturatum* in England, and in France, and in most of the London bedding catalogues.

FLOWER-GARDEN PLANS (J. V. Aucton).—You are all right; except No. 1. From the beginning of this Journal set its pages against the fancy of planting Scarlet Geraniums in the centre of anything; but no one has a right to question your privilege to plant it just as you think best. We would plant it with *Flower of the Day*, and a broad band of *Lobelia speciosa* all round it. If you would plant two rows in front of the evergreens in 6, the effect would be much better—say a row of *Yucca*, *Thunbergia* of ever-shrubs, and something white or variegated in front of it; but avoid yellow and scarlet in lines in front of evergreens as you would the plague.

LILIUM GIGANTEUM SOWING (J. Z. Chelsea).—The treatment of *Lilium giganteum* from seeds is so tedious a process, that we would not recommend you to sow any seeds. The best way to get it in a cold pit, just like so much of the other plants, is to sow it in a box or flat pan, and put it with watering, weeding, airing, shading, and seclusion from frost for three years; then to divide the seedlings out into single pots, or in an open bed of earth in the same pot, and in three more years some will bloom and some will not. Then, as to suckers, they are to be done just as the three-year-old seedlings; and in two or three or four years they will bloom according to their size—at first, the strongest will bloom in two years, and so on according to size and the skill of growing them. Your window plot does not seem to be a *Salomani* at all, nor anything like one; but we will give you a plan of a window plot idea. If it puts up suckers from the bottom, like the plant you had it from, do one or two of them as you did this last year; but keep the old plant just as it is, and see if it does not blossom this year two months earlier, and be altogether a much finer plant; and if you will send us a bit of it in flower, we will tell you the name.

DOUBLE CALLA ETHIOPICA (J. C. G.).—It is, indeed, very unusual to have double flowers on the *Calla*, or it is now called, *Richardia ethiopia*. We have never seen one, but we have heard of one or two being double before now. We would send you the copy of the *Number* for which you enclosed a most interesting and important article, or address.

VINES UNFERTILE (H. Christian).—According to your treatment, which we have carefully perused, we can assign no reason for your great disappointment, except an overabundant watering in the dull months of the year, and extra manuring; and some sudden check either at the roots or in the house. The appearance denotes over-luxuriance rather than sturdiness. We do not know any such art as you have practised, but we have always had hitherto been so successful. We have had another case presented to us, though not so bad as yours; but that we attributed to a neglect in watering in a very dry summer, which induced the roots to go down deeper than usual; and then, too, the border was screened from the sun in the beginning of August, when, in our opinion, the sun would have exerted a heating and ripening power more than any month in the year. Once we had the care of some imported Vines that, do what we would, came as you describe, and after trying them for three years and doing nothing we created a new Vine had plenty of fruit. We hear some strange things about Vines and Strawberries that season after such a sunny summer in England. A house of Vines we heard of the other day pruned in November, and generally allowed to break pretty well of their own accord about the middle of March, had taken to bleed all over like a shower-bath before the buds showed any sign of coming. The same was the case with some of the mildness of the winter we should not have been surprised if pruning had been deferred until spring; but we know that in that place the Vines are always pruned early—frequently before all the leaves have fallen. We know not except this one case, but we would go to the bottom of the matter, we may say—of bones was placed in the border. Could that have any such effect? We shall be much obliged if any correspondent or reader can throw better light on this correspondent's case.

GRAPES IN HOUSE WITH PEACHES (Little Gardener).—Black Hamburg, Black Prince and White Muscadine, and Sweetwater would suit you best, and either in pots, or planted out as bush standards in the way Mr. Nixon does at Drumcondra. If you meant having them on the roof, do justice to the other trees the Vines should be some 3 feet or 10 feet apart, and spar-pruned.

TEBROSUS CULTURE (An Old Subscriber).—Fresh bulbs of it every year from Italy should be potted just like *Hyacinths*, and in the same kind of soil, and in a greenhouse, and in the autumn, after the plants are ready, the flower-stem is 6 inches or 8 inches high; after that the plant is impatient of close heat, and very liable to red spider.

PREVENTING THE GOOSEBERRY SAW-FLY CATERPILLAR (H. W. H.).—Cover the whole surface of the soil of the bed or garden on which the *Gooseberry* bushes grow, with inches of straw, such as straw cut short. It effectually destroys the larva, and you will have no green and black caterpillars on your *Gooseberry* bushes.

GRASS, WEEDS, &c., AS A SOURCE OF HEAT (F. W.).—We cannot recollect all the details of the experiment, but we would advise you to load up, at eighteen months' Numbers—that is asking us to do what our readers should do for us. Weeds and grass will yield a good amount of heat; but to have it regular, and not in fits and starts, they should be mixed with something to insure a regular heat, from a slower decomposition. We have frequently used a lot of material, and the heat, and when done well, replace such. Our better regulator and continuous-heat-promoter in such circumstances is dry litter placed in alternate layers. The damp of the weeds and grass set all heating; and as from the openness air is gradually admitted, the heat will be more regular, and the material is nothing so much decayed. We have, from scarcity of material, made beds on the above plan, especially where we could turn them now and then. From such a bed, however, no steam must get to any plants, or they will be killed. In your case a close covering of zinc would keep all down, especially with a layer of ashes over it. On a large scale, to make a large quantity of coverings of this kind, and to have all unhealthy fumes down. Experience alone can tell how to manage such a case to the best advantage.

PAINTING FRAMES, &c. (H. M.).—As you would have to buy your white lead, and as you would have to deal with a dealer in order to get the best to the colour you want, as there are innumerable shades of white, and of stone colour and green which such tradesmen could show you and make, and which we could hardly manage were we to write a treatise on the subject, which we cannot do. Brushes can be cleaned, but at a much greater expense for labour than the price of having a separate brush for each colour of paint.

When not in use keep the brushes, after being roughly cleaned, in water. If you keep paint, place a little oil or water on the surface.

SUCCESSORS OF PERU (*A Learner*).—Sow the seeds about the middle of March. Place the pot at night near the fire-pace. When the plants are 1½ inch in height prick them off, say from four to six in a four-inch pot, and keep them in the window shaded from the sun at first. When these attain a fair size give them each a small pot, and keep in the window until the middle of May. The plants will be ready for potting the first week in June. If you like them into any good rich soil, and set them out in the open ground, they will do most matters take up the roots, store them in if dry sand, and treat as Dahlias.

VALLOTA PICTURATA CULTURE (*Idem*).—As respects Vallota, the word "dry" in the Dictionary should have been "dryish," to distinguish it from the usual meaning of the word, and a healthy plant does not grow slowly growing in winter. We regret the mistake, as we think your plant has been kept too dry. Some leaves, however, would go as a matter of course. Water gently now, making a few holes so as to allow the water to penetrate freely—that is to say, instead of deluging the plant at once give enough of moisture in a week, and the bulb will thrive very well for anything we see to the contrary.

CALECOLARIA CUTTINGS (*Idem*).—You were late enough with the *Calceolaria* cuttings in December. We put to thousands in October in a cold pit, and they must be moved for they are a perfect thicket—not one in two thousand missed. You may strike wholesale now in a mild heat, and in about as many days as they took in the autumn. Change and time are the great essentials in the autumn: a little heat and a splash are as requisite now. Growth was firm and stably in autumn, when the cuttings were made; heat would have started them the wrong way. The cuttings will now be full of sap and grow freely, and a little heat will not keep them from growing, but encourages the rooting process. Much of success in gardening depends on altering operations to suit different circumstances. When one gardener says that *Calceolaria* strike best in the cool, and another that they will thrive in a little heat, they are both right, and yet their practice may be both wrong in some instances and circumstances are not considered.

MISTLETOE SEED BROUGHT.—"I shall esteem it a favour if any of your readers would kindly send me a few seeds of the Mistletoe, as I am desirous of again attempting to raise this from seed. In reply to Mr. Deaton, I can only reiterate what I previously stated, that in this part of Devonshire or the adjoining county, Cornwall, we have not (to my knowledge) a so hairy specimen, and we in a hundred years have not growing; why we have no Mistletoe I am at a loss to say. I also know that, although ours is called the most lovely county of England, yet no person ever heard the Nightingale in these parts."—JAMES NICHOLLS, *Taristock, Devon*.

INK FOR ZINC LABELS (*Important*).—We have repeatedly published the recipe for making this. Last November (1861) we said, scrub the labels right with sand-paper, and write on them immediately, using a quill pen with the following mixture:—one drachm powdered verdigris (acetate of copper); one drachm of powdered sal ammoniac (muriate of ammonia); half a drachm of lamp black; ten drachms of water. Mix these in a two-ounce bottle and shake every time you use it. It is ready for use as soon as the verdigris and sal ammoniac are dissolved.

BEEVE CULTURE (*Hesmerlander*).—The effect bulbs are small, and will thrive with your seeds in the same parcel. Plant this month, about eight of them together in patches, 10 inches apart. A single row of five yards length is enough for a family, as the green leaves are the part used instead of roots. The plants, when they produce, are to be cut when the producers are cut off. After coal tar has been upon woodwork for several years, we think it would be no impediment to painting that woodwork either in visible green, or any other colour.

VARIANTS (*Flora*).—We are delighted with your letter, but Byron said, "There is a tide in the affairs of women which, when taken at the full, leads on to fortune; when it ebbes, brings down the soul to misery." When the tide is at the ebb, then we should not be overdone. The management of Pansies on your deep heavy clay soil, with a crust of garden soil on it, is to have a stock of them struck under a hand-glass every year, either early in April or after flowering, and to cut up the old plants every October, and divide the roots. You are quite right, as almost all ladies are about flowers. Pansies should never have a bed to themselves in any flower garden. A row of them round the Rhododendron-bed would be charming, and they would be just the things along the side borders. Mulching is better for them than any other colour.

CHILDREN'S NURSERY (*Idem*).—What a good idea to propagate plants in the nursery window to attract the dear young ideas to the delights of gardening, and to learn them not to pull things about. The way to strike cuttings in a south window, is to have a large pot, and a little pot with cuttings put inside it, then a square of glass set loosely on the top of the big pot, and you have been with water in the little pot, and you avoid everything that is likely to fail, for fear of damping the early impressions of the young folks. Begonias, old or new, will never do there. What you ought to have is a box the whole length of the sill, and of a colour to contrast with that of the walls of the house. Any material which will grow in a box as in a flower-bed. Pots outside windows are such a ceckeny institution, that we would avoid them as the plague, even six miles out of London.

LAMARQUE AND GLOIRE DE DIJON ROSES (*Idem*).—These are fine running Roses recently planted—say last year, and a little earlier. We should certainly like to advise you to leave the larger shoots at some length, but then Mr. Ken says he does not do so. He says he has seen all kinds of other climbers, and as you know them steer a course between him and him. Cut the young shoot of Lamarque quite down to the last eye or two, and the five-foot shoot to 3 feet. Do the same with all the bed and little shoots of the Dijon.

MANSFIELDVILLE SEARVINOLES (*Idem*).—It might do certainly in the verandah, but the *Solanum* leaves would be so long; but you must prune it well in the autumn, and cover it with mats in winter, and give it a final dressing in April; but you must not think of it from seed. It would cost you just eight times more from seed than to buy a nice little plant in a pot at once.

FLOWER GARDEN PLAN (*A Lover of Gardening*).—The plan of your new flower garden is exceedingly good. You must put two upright Yews—Irish Yews—in each of the grass fans near the two upper corners of each fan, as you have shown them in the circles; and if you could get pure white sand

or broken white sand, or broken white spar, to make a nine-inch-wide path-like mat all round the grass fans, and within 1 foot of the edge, then have some upright plant, as a *Humea*, in the centre of the two circles on these fans, you might challenge criticism from any quarter.

CERASTIUM TOMENTOSUM (*M. F. B.*).—It is a perennial, and is propagated from cuttings and by division of the roots. It does not seed with us. Did you not notice lately that Mr. Thomson, the gardener at Archerfield, when they have one of the best flower gardens in Scotland, does it from cuttings on the spot in April, just as if he were planting root slips for a ribbon-line.

VINEY ROOF OF IRBEED GLASS (*R. Weatherley*).—Never fear; your Grapes will not fall on account of that roofing. The colouring of the Grapes is more dependent upon a true admission of air than upon powerful light. In fact, a subdued light is best for them, they hang naturally shaded by the leaves.

VINE LEAVES WRINKLED (*An Old Subscriber*).—It arises from excessive vigour; the veins of the leaves do not diverge fast enough to make room for the rapidly developed parenchyma. If you wish to prevent it you must not keep the roots so well nourished; but if the Vine bears well we recommend you to leave the roots as they are, keeping the air of the house rather less moist, and ventilating a little more freely.

SYMPLEA CERULEA ANI HYDROCOEA TRIFLORA (*N. B. H.*).—We do not know where you can purchase these except of some of the principal nurserymen who advertise in our columns.

COCOA-NUT FIBRE REFUSE (*T. James*).—The sample you enclose is the right material.

PETRIAS ARGYREA (*Sabina*).—The specimens you sent do not show any sign of being eaten that we can discover. Had they been bitten the margins would have shown some signs of disorganisation. You surely do not mean to say that the fragments sent were once perfect and normal, and have since become deparated as they now are? They are exactly in the condition of the deparated sports which are so known in many species of Ferns, if you mean that the plants once produced normal fronds, and now such as these, we can explain it only on the supposition that it has sported; or else that originally there were two seedlings in close contact, and that one having this peculiar character has now got the ascendancy.

NAMES OF PLANTS (*J. H. Swanson*).—It is *Trillium uniflorum*, a perfectly hardy bulb, very pretty, but unfortunately smelling like garlic. (*G. H. Young* Ferns: 1, *Adiantum capillus-veneris*; 2, *A. cuneatum*; 3, *Selaginella denticulata*; 4, *S. uncinata*; 5, *Asplenium adnatum nigrum*; 6, *Davallia canariensis*, probably; but the specimens are altogether unfit for examination, too fragmentary, and from immature plants. They came from (*Botanic*):—1, *Doronicum pardalinum*; 2, *Juniperus communis*; 3, *Asphodelus luteus*; 4, *Pulmonaria officinalis*. (*Gerrase Wassse*).—It is *Ajuga reptans foliis variegatis*.

REARING EARLY CHICKENS.

MORE perfect weather unties our hands. It is no longer necessary to keep our chickens under cover. We may, and probably shall, be visited again with unkind, bitter, and cutting easterly winds; but present comforts obliterate past sorrows, and with mild atmosphere, growing grass, and increasing daylight we look for progress among our feathered stock. The task of a poultry-keeper at this season of the year is a growing one; brood succeeds brood, and one is hardly fit to move, and hardly at that age when they can dispense with constant care, before another takes its place. We once heard a gentleman say when he admitted he had no tool-house in his garden, he had no room for one. On inquiry, we found his gardens were five acres in extent. We have heard the owners of estates lament their inability to keep several distinct breeds of fowls for want of room. Necessity is indeed the mother of invention; and, if we look at the derivation of it, is the mother of finding out. Our chickens came off fast, and then we found the oldest could dispense with the endless attention they had enjoyed. To compass that object they must be removed from the younger.

Classification is valuable among poultry at all times, but never more so than when they are very young, as chickens of a fortnight require more attention than those of six weeks, and those of the latter age than others of ten weeks; it is a positive saving of time and food to divide and separate them. If no places will do for this purpose but those possessing all the conveniences that can be described or wished for, few can afford the luxury of several breeds; but as necessity made us find out proper places so, by telling our readers what they were, we may help them in a present difficulty, or lessen such in future.

A large old barn is the place where all our youngest chickens are kept. They are here till they are five weeks old. The spars are placed on the ground, which is covered with dust, sand, and lime. These have every care and food chickens can have, and

are always under cover; when the sun is out they are moved to the front that they may enjoy it. The ground in front of the coop in which the hen is confined is covered with sods of grass cut like those that are used to cover a lawn. These are changed every other day, and all the food given to these young chickens is placed on them. No one, unless they have tried, would believe the difference in result of food given in this way, or thrown on boards or on the ground. They have the undoubted benefit of fresh earth and growing grass, without the risk and injury of frost or chill of any kind.

Our premises are only large by comparison with others, and we wanted three walks, each capable of accommodating three or four hens and chickens. We have a small meadow, and dividing that from the garden there is an old, low wall; under the shelter of this we put four hens in ribs, about 5 feet apart—the chickens run out in the grass. There is a small hayrick—this affords a good place for some more. We know no place where chickens thrive better than under a rick. They have shelter from rain and from wind; they are free from draught, and they enjoy the greatest of all luxuries to a chicken—plenty of dry dust, and this is all full of grass seeds on which they feed. We were obliged to trespass to find a third walk, and we took possession of a gravel path in the garden. Our man will not believe us, and many will shake their heads when we declare our belief, founded on experience, that chickens (not fowls) do good rather than harm in a garden. We are quite prepared to admit they make some dirt, but that is easily removed when the chickens are old enough to do for themselves: the path is by the side of a strawberry-bed, and that is on a bank. Here the chickens work all day long, and nothing that has life can escape them. The surface of the earth is constantly being turned over, and we are sure this part will bear more fruit than any other.

We make these remarks week by week while they are fresh in our minds, and may be useful to our readers. We think what we have written will show to many that great space is not necessary for the management and separation of fowls. Two acres suffice for 150 fowls and their chickens, and for six distinct breeds.

THE CANARY AND THE BRITISH FINCHES.

(Continued from page 167.)

TALKING BIRDS.

AMONG caged birds the Cuckoo and Parrot are the best talkers, and of our British birds the Crow tribe are generally taught to talk. Of the smaller birds the Starling not unfrequently imitates the human voice, and I have heard of a hen Nightingale that could speak a few words.

But as it is of the Canary and British Finches I am now writing, I must confine myself to them. Among the former, two or three cases of talking birds have been recorded, and my father informed me of a Bullfinch that could call "mother."

The following note of a talking Canary, addressed to Dr. Gray, V.P.Z.S., by S. L. Southey, Esq., is extracted from the "Proceedings of the Zoological Society," No. CCLXLI:—"Touching that marvellous little specimen of the feathered tribe, a talking Canary, of which I had the pleasure a few days since of telling you, I now send you all the information I can obtain respecting it from the lady by whom it was brought up and educated, at this our homestead.

"Its parents had previously and successfully reared many young ones; but three years ago they hatched only one out of four eggs, which they immediately neglected by commencing the rebuilding of a nest upon the top of it. Upon this discovery the neglected and forsaken bird, all but dead, was taken away and placed in flannel by the fire, and after much attention it was restored and then brought up by hand.

"Thus treated and away from all other birds, it became familiarised with those only who fed it; consequently, its first singing notes were of a character totally different to those usual with the Canary. Constantly being talked to, the bird when about three months old astonished its mistress by repeating the endearing terms used in talking to it—such as 'kissie, kissie,' with its significant sounds. This went on, and from time to time the little bird repeated other words, and now for hours together, except during the moulting season, astonished us by ringing the changes according to its own fancy, and as plain as any human voice can articulate them on the several words:—

'*Dear sweet Titcheie (its name), kiss Minnie, kiss me then dear Minnie, sweet pretty little Titcheie, kissie, kissie, dear Titcheie, Titcheie wee, gee gee gee, Titcheie, Titcheie.*' The usual singing notes of the bird are more of the character of the Nightingale, mingled occasionally with the dog whistle used about the house. It sometimes whistles very clearly the first bar of 'God Save the Queen.'

"It is hardly necessary to add, that the bird is, of course, by nature remarkably tame—so much so, that during its season it will perch down on its cage on my finger, shouting and talking in the most excited state."

My father has told me there was a Canary exhibited in Regent Street, London, many years back that could speak a few words. In the catalogue of the Crystal Palace Bird Show for November, 1858, occurs the following entry:—"No. 153, Mr. Robert Standidge, 10, Reginald Road, Deptford, Mealy Turn Crown, age three years, £20. Sings and talks. Words spoken by this Canary:—'*Pretty Polly, pretty dear, call the Doctor, Polly sick, Polly sick, Pretty, pretty dear;* calls the dog Toby, Toby, and whistles him.' He speaks the above words and many others plainly. He was taught by the Parroquet, No. 306." I did not see the bird on the day I visited the Exhibition, as I understood he had been removed, and although I have not myself heard a Canary talk, yet, I think, the three instances I have named are tolerably conclusive evidence that the Canary is capable of imitating the human voice.—B. P. BREST.

DO BEES REQUIRE VENTILATION DURING WINTER?

THE following letter, from a thoroughly practical Scottish bee-keeper, confirms the correctness of the opinions upon this subject which have already been promulgated by—A DEVONSHIRE BEE-KEEPER.

"Being a reader of THE JOURNAL OF HORTICULTURE, I have seen your articles in reference to the injurious effects of internal moisture in some of your hives. I consider the idea of lining them with wadding is a good one, as from its nonconducting nature it is likely to prove beneficial. As I have a decided preference for straw hives I invariably use them. Owing to the nonconducting nature of straw, I have never found any of my stocks injured in the least by the condensation of moisture in the interior of the hives. Although I believe my hives in the winter season are more numerous stocked with bees than hives ordinarily are, as I have for a number of years made it a rule never to kill any of my bees, always uniting the inhabitants of my super-abundant hives to those set apart for keeping as stocks; consequently there are generally two swarms put into each hive in the autumn, and yet, with this excess of population, I invariably find the combs and interior kept in good order. With one exception I have never ventilated my hives at the top, and this solitary instance was accidental, having overlooked the closing of the hole at the top, about 1½ inch in diameter, through which the bees had gone up to the super, and from the nature of the straw covering above the hive, which was placed in a bee-shed made of boards, a free circulation must have been kept up. Although this was a strong hive the breeding in spring was retarded until the ventilator was detected and closed up.

"My method of treatment in winter is to place them about 2 feet apart, in what we call a bee-house—being a shed made of boards well coated with paint, about 4 feet high in front, and half this height at back—consequently they are kept free from external moisture; but I also place a dry turf on the top of each hive. I invariably keep their entrance open, unless the ground is covered with snow.

"During the calm fine weather which we had in January for several mornings in succession, I found three of my Ligurian hives with moisture running from the entrance-hole nearly to the end of the alighting board, at about an angle of 60°. On observing this I began to suspect that there would be an excess of moisture inside, but on examination, the hives were perfectly dry; not so the boards, however, as the upper sides of them in all three were completely saturated with wet. They were easily replaced with dry ones. On looking through my other hives I found the boards under most of my Ligurian hives damp to a greater or less extent; some of them only damp on the part underneath the combs where the bees were most numerous. There was only one of my hives of common bees that had an appearance

of moisture on the board, evidently because they were several weeks behind the others with the brood, and all the Ligurians are rearing a considerable quantity of brood. I may mention that on putting in the dry boards I enlarged the entrance; and, so far as I am aware, there has been little or no condensation of dampness internally since. I do not suppose the damp boards would have caused any serious injury if they had been allowed to remain, as all the hives were entirely dry—thus making very apparent the different effect which the same internal atmosphere would have on materials of different conducting qualities.

"I have some doubts if much good would be obtained by ventilating the hives in the beginning of winter, as they are evidently most liable to damp when the breeding commences in early spring.

"Next summer I should be glad to hear of your putting one or two of your Ligurian swarms into good straw hives, and on the following winter you will find them entirely exempted from the annoyance of dampness, even without top ventilation.

"Our bees had a few fine days about three weeks ago, when I observed a few bees in all my hives collecting pollen; but that is now (6th March) put a stop to, as we have a snow storm.—J. S."

VENTILATING HIVES DURING WINTER.

BEING thoroughly impressed with the paramount importance of a due regard to the careful ventilation of hives during winter—believing as I do, that more stocks are weakened, affected with dysentery, and perish annually from the neglect of this needful precaution than from all other causes whatever, if we except starvation—I therefore read with much pleasure Mr. W. Johnson's interesting paper on this subject at page 308.

I have tried various expedients to accomplish this desirable object. For some years I promoted ventilation by drawing all the slides, an empty super having been previously placed on the stock. Subsequently, thinking an upward current of air passing up between the central combs was possibly annoying to the main body of the bees there congregated, and too great an interference with their economy by unduly lessening the temperature of that portion of the hive, I ran in these slides, keeping only two on each side drawn. This I found quite sufficient in ordinary cases. Latterly, I was induced, on the recommendation of a most experienced Ayrshire apiarian friend, to discard upward ventilation altogether, and follow the practice generally pursued in that county, of ventilating exclusively below by means of ekes of the same dimensions, and about half the depth of the hives underneath which they are placed. This mode I found as efficacious as he described, and think that so simple a device should be resorted to in every case, whether the hive be of wood or straw, keeping it and its contents all sweet and dry, from the plentiful supply of pure air circulating below from the open entrance, and at the same time freeing the inmates from all annoyance of upward draughts, to which the first-described mode rendered them liable. Now studding and prejudicial to the health of our little favourites must be the practice of non-ventilators, particularly in hives with combs wrought close to the board, should they in addition use a contracted winter entrance.

I can also endorse Mr. Johnson's opinion as to the saving of food effected by ventilation. My experience also coinciding with his own as to the fact that "Bees kept in a comparatively dry atmosphere by thorough ventilation, will come through the most severe winter in our climate in better condition than when ventilation is prevented." The best illustration of this coming within my own observation was the observatory-hive I was enabled to chronicle at page 202, Vol. XXV., of THE COTTAGE GARDENER, as successfully withstanding 25° of frost, as shown on the thermometer behind, on the memorable morning of the 24th of December, 1860; in addition to the ventilation afforded by India-matting slides between the bars, that hive had plenty of vacant space below. The entrance, 4 inches by half an inch, if I recollect, stood fully drawn, and often have I heard the north wind, to which aspect it stood, blow through it, whistling on the zinc-covered fumigator space behind; and I feel convinced that had it not been for the thorough ventilation thereby afforded, from the closeness of the glass observatory and the damp consequently engendered, this hive must have inevitably perished.

I am glad to observe our Devonshire friend is turning his attention to this subject, and it will be interesting to learn the results of his experiments on Harbinson's plan of internal matting lining, such I should be disposed to think would absorb,

though, I should fear, not prevent the internal moisture; prevention in this as in all cases being preferable to cure. I regret my opinion does not tally with that of "A DEVONSHIRE BEE-KEEPER," as to ventilation being "only the substitution of a greater evil for a less one," by checking breeding in cold weather, and therefore, still "an open question." On the contrary, I have never yet seen a hive in a bad damp state in spring afterwards come to any great strength in population. Whereas, on the other hand, in our variable northern climate (which offers a marked contrast to salubrious Devonshire), we consider the retarding of the queen's breeding till the natural or customary period of the district anything but an evil, but on the contrary, as decided a gain as the late expansion of the blossom-buds on our fruit trees, which is the means of generally insuring a crop. Whereas their premature development is nipped by the same frost that injures, by checking the queen's production, forcing the nurses upwards, and causing the annoyance of quantities of abortive brood. Indeed, as everything in the animal and vegetable kingdoms must enjoy a winter of repose, I look upon a prolonged or premature stimulation of the queen's breeding as a very questionable proceeding, telling most prejudicially on her productive powers, and which by early ventilation in winter, and prolonged in early spring, I rather discourage.—A RENEW-SHIRE BEE-KEEPER.

MANAGEMENT OF LIGURIANS—HOW TO PLACE A SWARM IN A FRAME-HIVE.

THE stock of Ligurians which I obtained of "A DEVONSHIRE BEE-KEEPER" at the latter end of last summer being remarkably strong and healthy, I shall be obliged by his replying to the following questions:—

At present the Ligurians stand in the midst of five stocks of common bees. Is there not a danger of the breeds becoming hybridised on both sides in this position?

I wish to keep at least one stock of pure Ligurians, should I better accomplish this by moving them to another part of the garden?

In performing operations upon bees, such as transposing combs, searching for and removing queens, &c., does "A DEVONSHIRE BEE-KEEPER" use fumigation? and does he consider that fumigation acts injuriously upon bees? Whenever I have commenced operations in this way without fumigation on hives which are destitute of bars or frames, they have begun to kick up such a fuss that I have been compelled to desist without accomplishing my object.

I should also be glad to know the best mode of placing a swarm in a frame-hive.—G. F. B.

P.S.—I can fully bear out the statements advanced in THE JOURNAL OF HORTICULTURE, as to the superior hardiness of the Ligurian breed.

[Both species will most probably become hybridised under the circumstances you mention; nor is a removal to so short a distance at all likely to diminish the risk.

If it be desired to Ligurianise the entire apiary, the best plan will be to furnish all the colonies with Ligurian queens from the stock in your possession, leaving their impregnation to chance. These will at all events breed Ligurian drones, and next year may in their turn be weeded out and replaced by young Ligurian sovereigns bred as before from the original queen. She will breed true as long as she lives, and next year her offspring will have a fair chance of a true impregnation from the multitude of Italian drones which will then exist.

When bees are irritable, a little smoke is a wonderful peacemaker. It should, however, be used sparingly, and never pushed so far as to produce stupefaction, which, I believe, is very injurious to bees.

When it is desired to place a swarm in a frame-hive, the bees should in the first instance be shaken into a common straw skep. As soon as they are pretty quiet (say from ten minutes to a quarter of an hour after having), spread a sheet in a shady place and stand the frame-hive upon it, without its floor-board, and with its front raised on blocks rather more than an inch. Then knock the cluster of bees out of the straw skep upon the sheet immediately in front of the frame hive, which they will presently seek refuge in. Should they manifest any reluctance in so doing, Mr. Langstroth recommends that a few spoonfuls be scooped up in a large upon and shaken out close to the raised front of the hive. As these go in with fanning wings they will

raise a peculiar note, which communicates to their companions the joyful news that they have found a home. If combs are fixed in the frames, the crown-board may be removed and the cluster knocked out on the top of the exposed frames. The bees will disappear between them with the utmost alacrity, delighted to have met with a ready-furnished dwelling, and the crown-board having been replaced the hive should at once be removed to the position it is intended permanently to occupy.—**A DEVONSHIRE BEE-KEEPER.]**

HIVES FACING THE NORTH.

In answer to "J. L.," we have this reply from one of our most experienced apiarists.

"The experiment as to a north aspect for bees has been tried, sometimes successfully, but not always, and, perhaps, no general rule can be laid down, so much depending on locality, as natural shelter from wind, &c. Dr. Bevan says, 'Where due attention has been paid to other circumstances calculated to promote their prosperity, I have known them thrive in almost every aspect.' Dr. Dunbar remarks, 'It is obvious that hives ought not to face the direction of the prevailing winds.' 'So many circumstances,' says Mr. Taylor, 'have to be taken into account, that it is difficult to lay down any rule of universal application, and the bees have been known to prosper in all positions, from due south to north. A north aspect need not necessarily be an exposed one in winter, nor at other times one wholly uninfluenced by the effects of the sun. In forming a decision we ought to take into account the position of buildings, trees, &c. Moreover, the kind of house must have its weight in the scale, for where this is one closed at the front from the immediate influence of the sun, aspect is of less importance. Dr. Bevan placed his hives around the interior of an octagon erection, without perceiving any sensible difference in their well-doing.' The apiarian Geddes found that 'bees, standing on the north side of a building, whose height intercepts the sun's beams all the winter, will waste less of their provision, almost by half, than others, and yet in the spring are as forward.'"—**H. T.**

LIGURIAN BEES FOR AUSTRALIA.

I HAVE been favoured by Messrs. Neighbour & Son with a sight of, and permission to copy the following letter from Melbourne, Australia, making inquiries upon this interesting subject. The difficulties attending the transportation of bees to the antipodes are undoubtedly very great, although I am disposed to think they may be successfully encountered and overcome.

Any hints from the accomplished apiarian correspondents of THE JOURNAL OF HORTICULTURE which may assist in the solution of the problem, will be highly esteemed by—**A DEVONSHIRE BEE-KEEPER.**

"Melbourne, 26th November, 1861.

"Gentlemen,—The introduction into Victoria of the Ligurian bee having recently been a subject of much discussion here, may I ask the favour of your replies to the following questions in connection therewith:—viz.,

- "1.—Are swarms or colonies of the Ligurian bee procurable by you in England?
- "2.—What would be the invoice price per stock, sent in suitable plain, bar, or other hives?
- "3.—Would you undertake to forward them lived in such a manner as would insure their safe passage to Melbourne; or ordinary casualties excepted?
- "4.—Could you forward them immediately on receipt of an order—i. e., without waiting for any particular season? As far as this country is concerned they might arrive at any season with every prospect of success.
- "In addition, any brief observations on their management—if any management peculiar to this description of bee is necessary—would be much valued.
- "J. SAYCE, President of the *Apiarian Society of Victoria.*"

THE DISTANCE BEES FLY FROM THEIR HIVE.

THIS depends on various circumstances. Bees have been observed to fly nearly two miles in search of flowers, and even farther; but in fine, warm, calm weather in May and June, when bee pasture is abundant, they seldom go farther than from 800

to 1400 yards. The sweet perfume of the sycamore, the maple, and the later lime blossoms, has great attraction, and the bees have the means of communicating to each other the mode of finding the direction in which the best and sweetest flowers are placed. In June and July the white Dutch clover (*Trifolium repens*) is one of the greatest attractions to bees. A soft, warm, southerly breeze is the most favourable for honeydew, and also for dispersing the sweet odours of the clover and the lime tree, and in weather as described, I believe the scent of these and all aromatic flowers is carried "down wind" at least half a mile. In these times, when honeydew is on the oak leaves and other trees, and when the thermometer is at 75° it is dangerous to stand in the way of the exit and arrival of our honey-laden favourites.

In a fine, dry, and now-and-then electric atmosphere, bees will collect (during the honeydew) as much store in a week as they can in a common season in a calendar month.

The lime tree seems to have even an intoxicating effect or intense attraction, in the case of the wild bees. I have often observed the latter remain until it was nearly dark on the lime blossoms, and on many mornings after I have seen the wild bees by dozens lying in a dormant state under the trees, having remained all night, and this during most splendid weather a few days after midsummer.—**H. W. NEWMAN.**

[Mr. Huish relates facts which show that bees will fly four miles to a good honey pasture. He and Bonner visited the Isle of Bass at the entrance of the Frith of Forth. It is mostly covered with heath, and to their surprise they saw a number of bees collecting honey from its flowers. Not a hive of bees was kept on the island, and it is four miles from the nearest point of the mainland. Mr. Huish dredged flour on bees collecting honey on heath three miles from his apiary, and the person left to watch the hives saw many of the befooured bees come and enter them.—**EDS.]**

OUR LETTER BOX.

BEFF COCHIN-CHINA EGGS (*A Subscriber*).—Apply to any of the prize-takers who advertise eggs for sale in our columns. Galvanised iron netting is the best material for keeping fowls within the desired bounds. Three feet high would be enough for Cochins, and 6 feet high for other varieties. Do not have a bar at the top, or the fowls will try to fly up upon it. You will see the netting advertised.

IVY AND POULTRY (*C. H. B.*).—We do not think that fowls would eat Ivy leaves; at all events the leaves would not injure them, for the wail of a poultry run we know was covered with Ivy and the owls thrive well. You will find full particulars relative to Andalusians in our "Poultry Book for the Many," which you can have free by post from our office for seven penny postage stamps.

PIP OR GAPS (*Partridge-Cochin Breeder*).—The two diseases are totally different, or rather *pip* is only a symptom of a disease, being a dry scale on the tip of the tongue occurring when a fowl has rump, diarrhoea, or gapes. Cure the disease, and the scale disappears—never cut it off. *Gapes* betrays itself by making the bird frequently yawn or gape, and this is occasioned by little worms irritating the windpipe. Innutritious diet, want of green food, and impure water are causes of this disease. Put some rusty nails into the water; give more stimulating and nutritious diet. Put the patient in a box, place in the box at the same time a sponge dipped in spirits of turpentine on a hot-water plate filled with boiling water, so that the fowl must breathe the turpentine fumes for half an hour. Repeat this for three or four days following.

FOWL-HOUSES (*E.oucher*).—We have the window of our fowl-house turn on a pivot, so that we can ventilate in hot weather, day and night. In cold weather we close the window at all times.

BEE-HIVES—BEEES USABLE TO FLY (*T. P.*).—Messrs. Neighbour & Sons, 149, Regent Street, and 127, Holborn, supply flat-topped straw-hives, and will quote prices on application. They would also furnish either bar or frame-hives, fitted with the Woodbury comb-bar, which obviates the necessity for affixing guides-combs. The bees which collect pollen are healthy, whilst those which fall about the ground are probably suffering from dysentery. They must on no account be shut in, but the floor-board should be frequently changed. Feeding with syrup, to which a little wine or spirit has been added, is generally recommended in these cases.

CANARY LOSING ITS FEATHERS (*T. H.*).—Your Canary is suffering from over-fatness, caused by the feeding on hemp and rape seed. That is the cause both of the shortness of breath and the losing of the feathers; discontinue the hemp and rape seeds, give plenty of green meat, and allow the bird to bathe.—**F. P. K.**

LONDON MARKETS.—MARCH 17.

POULTRY.

There has been little alteration since last week. The supply is small with little demand. We do not anticipate a good trade till after Easter.

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last thirty-five years, the average highest and lowest temperatures of these days are 52.9° and 33.6° respectively. The greatest heat, 75°, occurred on the 27th in 1830; and the lowest cold, 14°, on the 24th in 1850. During the period 156 days were fine, and an 89 rain fell.

FIRST SPRING SHOW OF THE ROYAL HORTICULTURAL SOCIETY.

MARCH 19TH.

HIS was certainly a most decided success, and at the same time the most thorough breakdown I ever yet saw in our arrangements. No body of men could foresee that four thousand crinolines, each fourteen yards round, could meet at four o'clock of that day, where four hundred could hardly be expected; therefore, there was only room allotted for fourscore crinolines on the supposition that one-half of the number could find sufficient amusement in eyeing the other half from the outside, while that half were eyeing the happy result of the most happy resolve of giving vent and ventilation to the powers of gardening and competition in London in the month of March.

Those not there never saw such fun or so much good humour in so small a compass in all their days—at all events, I never did, only I was in a tremendous fix three or four times before I could release myself from my task. The fact is, I miscalculated the numbers that might be expected in the afternoon, just as the Council did, and sauntered about all the morning, or stood apart gathering information to rub off the rust of the last few months; and wherever I could see a right Fellow of the Society in the right place for me, off I went for a gleaning, instead of doing what I ought to have done in the first instance. But catch me that way again, and you may venture to expect catching the Council of our Society in such another fix.

Their Royal Highnesses the Duchess of Cambridge and Princess Mary were more fore-knowing than your humble servant, for they were there early in the day, attended by the Duke of Buckingham, Sir Wentworth Dilke, Mr. Fairbairn, and others.

The Council and Committee-room at the entrance of the garden was the place where the Exhibition was held, instead of in the grand conservatory, and the result was as just stated—there was not room for one-twentieth of the company. The room was exceedingly well arranged for effect. All round the walls were the large specimen plants in running collections, chiefly from the nurseries. In front of them and shelving down to the height of one's knee were placed the various displays of smaller plants and the large collections of Hyacinths. Tulips, Polyanthus Narcissus, Primulas, Cinerarias, Roses, Cyclamens, collections of cut blooms, fairy-like Air Plants, little novelty gems, great botanical curiosities—as the Bird Plant of Mexico, from Mr. Salter; the morphological Primulas of the Messrs. Downie, Laird, & Laing; the

Pimelea something and three Hardenbergias from the Messrs. Veitch, who also had one of the most puzzle-peg plants in Europe there from Manilla, sweet as a Violet, and no man in England or out of it can name it and be certain of being right. It is an Amarylloid of the Pancratium group; but whether it be a Pancratium, or a Hymenocallis, or a Choretis, or what, no man on earth can tell till the seed is seen.

Then, in the centre of the room was a span-roof-like stage of vast beauty with the most ordinary spring-flowering plants at one end, and falling gradually on both sides to the other end into the most rare and expensive things which money, by introducing novelties, or skill in new creations could produce so early in the season. And up and down on this middle stage could be seen the next best improvement in gardening skill, after the Hyacinths, on either side—I allude to those dense and delicate masses of the Lily of the Valley from the Society's own garden at Chiswick. Nothing nearly like to them has been seen in London by the writer, who has seen most of the moves there for the last thirty years.

I venture a prophecy that there is not one new member of the Society out of one hundred who might not learn a lesson from a leaf out of Mr. Eyles' book in forcing flowers, the very best part of gardening after all when one cannot get much out of doors. And what is the use of all that crinoline to married people if the drawing-rooms are not full of forced flowers from Michaelmas to May-day, besides a change of dinner decoration flowers three or four times a week? Botany and bedding plants, florists and pomologists, are just as if they were fresh from the flood, as compared with what I mean, in the eyes and affections of such people as thronged the First Spring Meeting of the Royal Horticultural Society. That is my prophecy, and the Lily of the Valley was the cause of it; and I would be more proud of being the grower of those I saw than to have been the successful candidate for the honour of all the Orchids there. But there is selfishness even in that pride. Any man who could do all the winter flowers in that style would never be one month out of a situation as long as any one now alive could remember when crinoline was the fashion. Book that as quite certain, and think of it now and then, and I shall turn and book the prizes.

Beginning with the Hyacinths, in which Mr. Cutbush, of Highgate, was first, and Mr. Wm. Paul second, each with eighteen kinds in collection, and each with eight times as many more for effect and from good will to the Society. All the nurserymen who exhibited displayed the same evidence in their desire to further the progress of our craft. Names and classes of flowers without the colours are alike tiresome and most tedious for ladies; they tell me so over and over every year for naming so many of them, and having had a grand chance here, I took them all by their colours, and No. 1 is the best in each shade, No. 2 the next best, and No. 3 next—thus: The highest reds or crimson, 1, Aurora Rutlands; 2, Lina; and 3, Amy. The next lower shade of red and crimson,

1, Milton; 2, Von Schiller; 3, Robert Steiger; 1, Mars; 5, Madame Rachel; and 6, Baron von Rothschild. The third shade of red, 1, Koh-i-Noor; 2, Mrs. Beecher Stowe; 3, Queen Victoria; 4, Susannah Maria—four splendid sorts. The next we come to is pale blush. Here, 1 is Norma; 2, Lord Wellington; and 3, Sultan's Favourite. Then, for contrast, I took the largest, so as to have the pure whites after the porcelain blues, just as the light blushes are before the blacks. I am almost certain now that it is how the colours ought to be arranged in planting or in setting the plants in bloom on a drawing-room side-table, or as most ladies would set them, and say nothing about it.

The blackest there were—1, Prince Albert; 2, General Havelock; and 3, Blackbird. Dark blues, 1, Argus; 2, Baron Von Tuyl; 3, Prince of Saxe Weimar; 4, Laurens Koster; and 5, William I. Next is porcelain blue, a very rich class of the richest substance in the flowers—1, Orondates; 2, Bloxberg; 3, Couronne de Celle; 4, Grand Lilas; 5, Van Spierk; and 6, Requius.

Now the pure whites fall in—1, Madame Van der Hoop of course (my madame of such purity, and with a loop too, could not be kept out of the first rank); 2, Mont Blanc; 3, Queen of the Netherlands; and 4, Alba Maxima. Then mauve—1, Prince of Wales; 2, Madame Harzin; 3, Honour Overeen. Then yellow—1, Ida; 2, Victor Hugo; and Aurora, red and yellow veined.

Among the newest Hyacinths in which Mr. Cutbush took the lead I noted Reine des Hyacinths as a deeper red than Lina; Pélissier, also a good red; and Due de Malakoff, quite a new colour, in shades of red and yellow.

Then, a large collection of Persicum Cremlans from the Wellington Road Nursery; another very interesting collection of distinct kinds of Primula sinensis, including feidolia, the Fern-like leaf kind, both white and red. Other collections of the same from Messrs. Cutbush, Dobson & Son, and Bull, of Chelsea. Some Primulas, also, from Mr. Turner, of Slough, and most curious green spotted Primulas from the Messrs. Downie, Laird, & Laing, every petal of these and all the stamens were incipient plants; and they had a hen-and-chicken Cineraria going to sport for something. By these were the only set of "dorstists" Cinerarias from Mr. Turner, of which George Eyles, a deep crimson self, and Mrs. Harry, a deep purple edge, and a large white eye, were my favourites.

The Messrs. Smith, of Norwood, had a large collection of their strain of Cinerarias right opposite, of which Blue Bonnet was the first a lady would fancy; then Princess Alice, a lively dower; Prince Alfred and De-lancey being the next best.

The only new Geranium there was Flower of Spring, from Mr. Turner, side by side with a good sample of Madame Custado Rose, and another darker one, too soon in the season to judge. There were myriads of fine-leaved and variegated plants from Messrs. Veitch, Williams, Bull, and Parker, the prettiest of them all being the elegant *Cyperus alternifolius variegatus*. Here was a very old plant seldom seen, from General Fox's garden, the old *Maria striata*, also called *Lis sinensis*, and an excellent cross *Rhododendron* from Edgeworth's by ciliatum, in which the habit of ciliatum seems stamped on the other, while the larger bloom and the scent are returned. Another of them, a cross of Edgeworth's by Gibson's, has not resulted in giving the closer habit of Nigherry to the Silkkin plant, but the flower is grand. Mr. Standish sent a Skimmia which, if it will have red leaves like japonica, would be a good thing; and up and down on that entire stand were some nice Roses from Mr. Todman, gardener to R. Hudson, Esq., Clapham Common.

A species of Phyllagathis was one of the best fine broad-leaved plants there. It was from the Messrs. Veitch; and *Acaea erio-carpa* was one of the best of them there from the same firm—a dense-growing, very small-leaved *Acaea*, one mass of bloom.

All round the walls were the nursery collections, and chiefly such as various Epimises, Eriostemonas, Acaeas, Boronias, Azaleas, Rhododendrons, Camellias, and Eriias; and there was one collection of excellently forced spring-flowering plants from the Messrs. Fraser, beginning with a snowball Guedler Rose, about the size of a show Polyanthus, and as well bloomed as you ever saw it in May out of doors. Geranium Reine Hortense, a forcing kind I never saw before; Persian Lilac; Phaladaphnocranaria, the old Syringa of the ancient shrubberies, and none better; the Goubault Tea Rose, Dieris, Dautzia, Adonis, Salix palustris, and something else I lost between two magnificent erinodes. Of Hippeasters (called Amaryllises by the Society, who ought to know that they are no such things, but

course as corduroy against satin as compared with the race of the Belladonna, the type of the true Amaryllis), the best were from Mr. Parker, and he had one very superior kind by itself, the only real improvement I have seen in Hippeasters since 1840.

Hippeasters, by the way, are far more useful in private families than Amaryllises, and no race of bulbs are more easy to manage and to have in bloom nine months of the year, if one had a good assortment of them, which no one near London seems to have, as you never see more of them in London than the Aulicum and Johnson breeds, and all the breed of Aulicum is very coarse. There is a very good Hippeaster to breed from now at Chiswick garden, sent by the collector from the north of Rio, the Amaryllis, he calls it, with the white stripe in the leaf—that is the true Hippeaster reticulatum, the Amaryllis striatifolium, of "Botanical Magazine," 2113, and those Fellows who are fond of the voting by ballot ought to look after it, to smooth down and to give some sort of shape to the Ragged Jacks of the platyptalum variety of Aulicum, from which most of the London Amaryllises are descended.

Talking of shape, the best-shaped Camellia there was named Sarah Frost, and sent from Mr. Standish, a godsend to our buyers, for which I saw a first-prize ticket given as I was getting off from the Corchularias within; and there was another prize ticket to him for more Camellias, but I could not see the names.

Mr. Salter, of the Versailles Nursery, had a noble match pair of tall Camellias as you entered the door, one on each side.

Mr. Young, gardener to R. Borelay, Esq., Highgate, was the only gardener who ventured out with superior specimens, and he was very successful there and in bulbs, well nigh knocking the big growers of them the one against the other.

The Duchesse de Berri Camellia, a pure white, seems to be nearly as good as the old white and Fumbrata, two Camellias which have never yet been beaten, but that Duchesse has something that way in her eye.

Mr. Williams, of the Paradise Nursery, set up two large *Vanda survis*, a match pair, one on each side of a big *Cyanophyllum magnificum*, the three best sets for effect there; and in front of them were a host of most valuable plants, one of them *Sphaerostema marmorata* growing exactly as *Beaumontia grandiflora* ought to be seen when intending it to bloom; and several *Ocledis*, Amaryllises so called, and a huge lump of *Sarcocolla purpurea*.

There was a fine new *Laela* from R. Warner, Esq., the lip in the way of purpurata, the sepals spreading wide with a peculiar tint of light cinnamon colour, and that colour dotted over partially like a thush's egg.

A vast lot of early Tulips from Mr. Cutbush, and Mr. Young his rival, and a large assortment of *Polyanthus Narcissus* from the former made the farthest front of the room as gay as the Hyacinths certainly did that on entering the end door.

The box of Cut Roses from Mr. Paul was really prime stuff for March; but Mrs. James Stoddard defeated him and all our florists as completely as she overcame your humble servant with her French paper Dahlias at the Crystal Palace. We must have a leaf out of her book if we expect Roses ever to be circles or half-balls. And were it not for the ungallant manner Mr. Eyles went about his Lilies of the Valley, Mrs. Conway, of Earl's Court, Brompton, would have put our gardeners to shame with her first-prize collection of them. Let Mrs. Conway but get one leaf out of Mr. Eyles' book on these Lilies, and she is booked herself for life in the books of all the best ladies of Brompton who could then almost add them to their bonnet ornaments—and why not?

A lot of young *Fuchsias* from Messrs. Carter, were said to be double, and all the Luchias, in summer, to be tricolor in the way of the *Aurantiacs*, the colours at present indicating that character.

D. BEATON.

Again we florists must claim, I think, a victory, for surely we contributed the most extensive and interesting portion of this day's Exhibition. What would it have been without the Camellias and Hyacinths? And who would have cared for the Eriostemonas, &c., if they had not these to fall back upon?

Camellias, I must honestly say, disappointed me. It was evidently a mistake to exclude nurserymen. But what were private growers about? Surely one would think there would be some plants to be found; and it withal strikes us that it would be well to offer prizes for cut blooms in boxes, as for Dahlias, &c., as we should then have a better opportunity of judging of the relative value of the sorts.

Unquestionably the finest Camellia there, in shape, was Sarah Frost, an American variety, sent by Mr. Standish. It was absolute perfection, laid out most regularly, and a delicate rose colour with white stripes. Duchesse de Berry, too, was another exquisite in shape, and a beautiful clear white. Then there was Mesta Rosea, very fine; and Moutaroni, a large and good white. These all were fine plants, sent by Mr. Standish. Queen of Beauties, is said to be the finest striped Camellia out, and has been introduced by Mr. Bull, from Belgium.

Amongst Hyacinths there were several flowers of considerable novelty, but we look for an improvement in this flower. We want large and better shaped bells, as well as finer trusses. A new kind in Mr. Cutbush's six seems likely to be the parent of a different strain. It had very large and waxy bells, and was semi-double, but there was a novel appearance about it that augured an advance. Due de Malakoff was a very fine mauve flower with crimson stripes, very remarkable in appearance and attractive. Macaulay, was a fine striped red; and Queen of Hyacinths, a very bright red. Paix de l'Europe and Plessier, were also very good. Amongst the older kinds, Argus, blue, with white eye, is striking and good. Madame Hodges, Prince Albert, Grand Lilas, Charles Dickens (blue), Grandeur à Mercerie, were all excellent, and I have no doubt the "chief." I saw there will tell us what he thinks about them as to their decorative properties.

We must not omit the three tidy little plants of Madame Turtado Rose, sent by Mr. Turner, which fully sustained its character as a fine Rose. There was a plant, too, of one of the new candidates for public favour, sent by Mr. Turner, but so high up that I could not see it very well, but it seemed a very bright-coloured flower, well cupped; if so, it will be an improvement. It was named Francois Lacharme. It was just a little foretaste of what we are anxiously looking out for.

Cinerarias were not sufficiently forward for this Show, nor did we see anything of very great promise amongst them.—D., Deal.

PRIZE LIST.

Eighteen Pots of HYACINTHS, twelve distinct kinds (Open).

First, W. Cutbush & Son, Highgate Nurseries. Second, W. Paul, Cheshunt Nurseries, Waltham Cross. Third, C. Gimbley, Alibon Nursery, Stoke Newington.

Twelve Pots of HYACINTHS, distinct kinds (Prize offered by Mr. James Cutbush—Amateurs).

Prize, W. Young, gardener to R. Barclay, Esq., West Hill House, Highgate.

Six Pots of HYACINTHS, distinct kinds (Amateurs).

First, W. Young, gardener to R. Barclay, Esq., West Hill House, Highgate. Second, A. Carr, gardener to E. Noakes, Esq., North Hill, Highgate. Third, T. Todman, gardener to R. Hudson, Esq., Clapham Common.

Six Pots of HYACINTHS, new distinct kinds (Open).

First, W. Cutbush & Son, Highgate Nurseries. Second, W. Young, gardener to R. Barclay, Esq., Highgate. Third, W. Paul, Cheshunt Nurseries, Waltham Cross.

Twenty-four Pots of TULIPS, three bulbs in a pot, six kinds (Nurserymen).

Prize, W. Cutbush & Son, Highgate Nurseries.

Eighteen Pots of TULIPS, three bulbs in a pot, four kinds (Amateurs).

Prize, W. Young, gardener to R. Barclay, Esq., Highgate.

Twelve Pots of TULIPS, three bulbs in a pot, three kinds (Amateurs).

Prize, W. Young, gardener to R. Barclay, Esq., Highgate.

Six Plants, CAMELLIAS, distinct kinds (Amateurs).

No competition.

Four Plants, CAMELLIAS, distinct kinds (Amateurs).

No competition.

Single Plant of CAMELLIA (Open).

First, J. Standish, Royal Nursery, Bagshot. Second, J. Salter, Versailles Nursery, Hammersmith. Third, A. Henderson & Co., Fine Apple Place, Edgware Road.

Nine Pots of LILIES of the VALLEY (Open).

Prize, Mrs. Mary Conway, Earl's Court Nursery, Old Brompton.

Six Pots of Stove AMARYLLIS, three kinds at least (Open).

First, W. Parker, Exotic Nursery, Tooting. Second, W. Lakeman, Grove Gardens, Hendon.

Six Pots of any kind of PRIMULA (Open).

First, T. Todman, gardener to R. Hudson, Esq., Clapham Common. Second, Messrs. Dobson & Son, Woodland's Nursery, Isleworth. Third, W. Cutbush & Son, Highgate Nurseries.

Twelve Forced GERANIUMS (Open).

No competition.

Twelve Pots, SPRING PLANTS in flower, not forced (Open).

Messrs. J. Veitch & Son, Royal Exotic Nursery, Chelsea and Exeter. Second, J. & J. Fraser, Lea Bridge Road Nurseries, Leyton, Essex. Third, A. Henderson, Fine Apple Place, Edgware Road.

Twelve PLANTS in flower, forced.

First, J. & J. Fraser, Lea Bridge Road Nurseries, Leyton, Essex. Second, W. Young, gardener to R. Barclay, Esq., Highgate. Third, W. Cutbush & Son, Highgate Nurseries.

Prizes, as under, were awarded to the following miscellaneous plants and flowers:—

First, W. Cutbush & Son, for collection of 50 vars. of Hyacinths. Equal ditto, A. Henderson & Co., for collection of Hyacinths and Tulips; W. Paul, for collection of 100 Hyacinths. Second, W. Cutbush and Son, for collection of 35 vars. of Narcissus. Equal ditto, J. Standish, for collection of 5 Camellias grown in the open air. Fourth, Paul & Son, for a box of cut Roses. Equal ditto, R. & A. Smith, Ditchwich, for collection of new and rare plants. Extra ditto, J. Salter, for two pots of variegated Lilies of the Valley.

THE ADVANTAGES AND DISTINCTIVE FEATURES OF THE MANETTI STOCK.

I WILL NOT enter upon the question, Which is the best stock, Manetti, or the Briar? Much depends upon circumstances. I should fancy that the Briar 2 feet high would be the most "convenient" for thoroughbred Rose lands, because Manetti Roses would generally grow up into pole Roses, which might be "inconvenient."

My Acidalies are between 9 feet and 10 feet high, and Paul's Victoria, apparently dead at the spring of the year, is now between 7 feet and 8 feet high. The great advantage of Manetti Roses is, that they will do "wonders," where the Briar Roses will do nothing, even with the best attention and highest cultivation.

It cannot be denied that some Roses here which do well on a Briar, do badly on Manetti, and vice versa. However, I never knew one grow badly on Manetti that was of free growth and good constitution. Moreover, some (as the White Bath) which are tender, but of free growth, do well on Manetti, and better than they do on a Briar. Others, like Marce, which are of free growth on a Briar, do badly on Manetti.

It appears to me that some of the Manetti Rose failures have occurred from placing unsuitable Roses on the stock. Suitability is the very soul of Rose prosperity. Each Rose, each soil, each season, is a law to itself. The Manetti stock sends up so much sap, that it requires a free grower to carry it off. Some spoil their Manetti Roses by cutting them and treating them as if they were Briar Roses, from which they differ in many particulars.

First, You cannot cut (for show purposes especially) a Briar Rose too hard, and you cannot cut a Manetti Rose too lightly; in fact, like a Hybrid Bourbon or Hybrid China, or strong-growing white Noisette, merely taking off the tops, thinning out useless wood, and cutting the side wood to a good eye are all that it requires.

Secondly, Briar Roses should, on an average of years, be cut according to circumstances, about the 15th of March, when the wind is in the south, or south-west. A Manetti Rose you may thin out after Christmas at the base, and you need not cut the tree in the main till after the whole of its flower-buds are formed. You will then see what, and where, to cut.

Thirdly, You can scarcely plant a Briar Rose (it should always be mulched unless your ground is "mucous," and able to supply the roots with moisture by capillary attraction) too shallow; and you cannot plant a properly-propagated Manetti Rose too deep—i.e., over the collar of the bud. The Manetti stock should never be exposed, as the sun stews the juice out of it, and it "rhynocerates" or becomes as dry as a walking-stick; hence it will not do for standards.

Fourthly, A Briar Rose makes roots slowly and sparsely; a Manetti stock makes them quickly and abundantly, and travels fast for food. The former is, therefore, more impatient of drought than the latter.

Fifthly, A Briar Rose should be manured in the winter, but a Manetti Rose needs not to be manured much till after you see what crop it is about to bear. As manure runs quickly out of my inferior grounds, I manure at all times; and no man does, or can, manure more highly.

These are some, and perhaps only some, of the points of difference.

Let me now, even at the risk of repetition, point out some of the advantages of Manetti Roses, properly propagated, properly planted, properly cut, and properly attended to at all times.

Firstly, For pot purposes there is nothing equal to it. How do men get their "novelties?"

Secondly, Manetti Roses when sick—yes, very sick—may be taken up and re-struck and recovered. I never knew a sick Briar Rose ever thoroughly recover.

Thirdly, A Manetti Rose is more easily defended in hyperborean winters; and, even if it is killed to an inch from the point of union, it may become a mighty tree the same year. In the spring of 1861 I did not know but all my Duchesses of Orleans were dead, but they became noble plants, and were laden with abundant, continuous, and large first-class flowers, and they are now in good condition.

Fourthly, In able hands (I include a pennyworth of brains), Manetti Roses will do well in all lands, and in lands where it would be useless to plant a Briar H.P.

Fifthly, It is an earlier, later, more continuous, hardier, and more productive stock than the Briar in inferior lands.

Sixthly, The blooms come to perfection quicker, and are larger (here at least) than the same Rose would be on a Briar, planted by the side of the Manetti Rose. The blooms also are of a finer colour, and the petals more substantial. These things are no more than the natural issue of a stock so redundant in succour, and so quick to root.

Seventhly, The Manetti Roses, if planted over the collar of the bud, will probably become Roses also on their own roots; and if you, in due time, heal up 4 inches over the lower shoots they will also become Roses on their roots. I have taken off several of these from La Ville de St. Denis and others. I have no doubt that the great body of my Manetti Roses are double-rooted.

Eighthly, You may, with care, transplant them in your garden in August or September without detriment. The removal in gloomy weather stops the redundancy of sap, the tree takes again in a trice, and ripens its wood all the better. I have over a thousand Manetti Roses, and three years following I find that those which I bought of Mr. Gill, of Blandford, were planted the 10th of October. No Roses have ever done better. None can look better than they do at this moment. You may also plant them in spring with success weeks after you would dare to plant a Briar Rose.

These, then, are some of the advantages of Manetti Roses. It is remarkable what a mess propagators and cultivators have made of it between them. The propagators budding it too high, and the cultivators misunderstanding it at all points. I did the same once: my plants lasted "two years." They came to Blandford from Mr. Francis, a nobler plant I never saw. I have the same Roses that I "murdered" in hundredths, some of them 5 feet and 6 feet high, and a mass of efflorescence in the season, their stiff stalks being dragged down to the ground with the weight of flowers. Among the victims I remember were: Général des Batailles, Général Jacqueminot, Baronne Prevost, and Jules Margottin. Come and see them next summer about the 16th of June, and you will go home and buy a thousand, and I hope an equal quantity of "common sense."

I may add, that I bought some admirable Manetti plants of Mr. Rivers, especially Madame Louise Carique, the finest-habited new Rose and one of the most beautiful that has come out since Cambacres appeared. Had Manetti Roses always been budded as Mr. Rivers' and Mr. Gill's are budded (close upon the roots), this noble stock, so valuable in every respect, would never have wanted a defender, for, before the cultivator could have spoiled it, the Rose would probably have been established on its own roots, and out of harm's way.

I do not impugn for a moment either the motives or the experience of the opponents of Roses on the stock of Signor Manetti. It is but candid and truthful to say, that, except nurserymen and myself, I never met a person who did not suspect it to be a failure, or say that they disliked it. And yet these very men come and look at a patch of 425 Roses here in a place that was a "wild duck" pond, and say, that they never saw such a dorsal sight in their life.

I have said the stock is early. Last year it gave me twenty-four winners on the 18th of June at Dorchester. Usually they begin about the 6th of June, and never stop one moment till frost and snow cut them off. I hope to be able to take some to Kensington, June 11th. I count upon sixty blooms of Solfatere (own root), and twenty-four trebles, or, at least, twenty-four singles; but, of course, without an early spring this cannot be done. I have rubbed out "impossible" from my dictionary, and, at any rate, as the boy said of the "fiddle," "I will have a try."

In conclusion, a West Indian summer, or a cold wet one,

makes no difference here to Roses on the stock of Signor Manetti. For the last four years they have astonished me and every visitor. I have found what Mr. Rivers has said of Manetti to be true to a letter. Cut out the eyes from the stock and do not cut the plant hard, and you will not be pestered, as you are with Briar Roses, by suckers. I rarely ever see a Manetti sucker here. I never saw above one or two in my life from the roots, and very few from the stock.—W. F. RADCLIFFE, *Rushon*.

HARDY HERBACEOUS PERENNIALS.

(Continued from page 173.)

JULY.

Red, Scarlet, Crimson.

Cheone barbara coccinea, 4 ft.
Conopsis divaricata, 3 ft.
C. unguis-cati, 2 ft.

Aster laxus, 2 ft.

Yellow.

Bidens proserpa, 6 ft.

Blue.

Aster grandiflorus, 2 ft.
A. patens, 2 ft.

The list we have published is enough for a large plot of the garden; but of course the owner may reduce the number, or even increase it at pleasure. It would be a great convenience to

have a stock of each species in a reserve garden, for the purpose of either changing the plants or adding to them when it may be thought advisable. The point to attend to in planting is to distribute the species so that the times of blooming may be spread over the whole border or borders; then, in viewing them the eye would always perceive in as moderate a space as possible one, two, or more plants in flower. In order to afford a guide or example how to manage the planting, I have selected from the list as many plants as would furnish a border 36 feet long. The example might, of course, be repeated to any length. The front row at a foot apart would hold thirty-six plants; the next, at 1 1/2 feet distance, twenty-four plants; and the other two, at 3 feet apart, twelve plants in each: thus it will be understood that eighty-four kinds would furnish a border 36 feet in length. The reader will observe that I have used scarcely any of the large family of *Piloxes* or *Iris*, and several others—in fact, many of these richly deserve a border to themselves. If thought desirable, the front row might have a batch of *Crocuses* and *Snowdrops* between each of the permanent plants with a good effect in early spring.

I trust this attempt at classing in colours, heights, and the times of flowering of herbaceous plants will be received with due allowance. No doubt it might be greatly improved, and I should be glad to see our old-fashioned flowers once more have a prominent place in our gardens.

FIRST ROW, 3 inches to 9 inches in height; 36 plants 1 foot apart.

- Ajuga pyramidalis*, Blue, May.
- Eriophora prostrata*, Yellow, July.
- Primula flore pleno*, White, April.
- Cyclamen com.*, Red, February.
- Hepatica (double Blue)*, Blue, April.
- Lorox corniculatus fl. pleno*, Yellow, July.
- Anemone alpina*, White, May.
- Hepatica (double Red)*, Red, April.
- Colandrinia speciosa*, Blue, June.
- Cheiranthus Marshallii*, Yellow, May.
- Epidemium macranthum*, White, Apl.
- Gnaphalium dioicum*, Red, May.
- Campanula pumila*, Blue, July.
- Alyssum saxatile*, Yellow, May.
- Oenothera taraxacifolia*, White, July.
- Phlox verna*, Red, April.
- Aubrietia purpurea*, Blue, May.
- Eranthis hymalis*, Yellow, February.

- Mitella diphylla*, White, April.
- Dianthus alpinus*, Red, June.
- Gentiana acedns*, Blue, May.
- Achillea tomentosa*, Yellow, July.
- Anemone multifida*, White, June.
- Colchicum autumnale rubrum*, Red, October.
- Prunella grandiflora*, Blue, August.
- Thalictrum alpinum*, Yellow, June.
- Ajuga reptans alba*, White, April.
- Sedum roseum*, Red, June.
- Centha septemfida*, Blue, August.
- Gailthia palustris plena*, Yellow, May.
- Campanula pumila alba*, White, July.
- Silene Schaffrii*, Red, April.
- Crocus autumnalis cerulea*, Blue, Oct.
- Convallaria aurea*, White, March.
- Cornus suecica*, White, March.
- Dentaria bulbifera*, Red, April.

SECOND ROW, 1 1/2 foot to 2 feet: 24 plants 1 1/2 foot apart.

- Aquilegia Skinneri*, Red, May.
- Lilium monogynum*, White, July.
- Rudbeckia Newmanni*, Yellow, Aug.
- Campanula speciosa*, Blue, May.
- Gent. coccinea*, Red, July.
- Aster laxis*, White, November.
- Bundelium subciliatum*, Yellow, August.
- Delphinium grandiflorum*, Blue, June.
- Dielis tra spectabilis*, Red, May, June.
- Dianthus superbus*, White, August.
- Carexpus tenuifolia*, July.
- Aster stellata*, Sept.

- Aquilegia formosa*, Red, June.
- Asphodelus ramosus*, White, May.
- Lupinus californicus*, Yellow, July.
- Paistilla verna*, Blue, May.
- Lycchnis fulgens*, Red, July.
- Ranunculus acutifolius*, White, May.
- Coronilla coronata*, Yellow, July.
- Aster grandiflorus*, Blue, September.
- Ononis spinosa*, Red, July.
- Aster emineus*, White, October.
- Trollius americanus*, Yellow, June.
- Aster concinns*, Blue, October.

THIRD ROW, 3 feet; 12 plants 3 feet apart.

- Lupinus polyphyllus*, Blue, July.
- Carexpus lanceolata*, Yellow, Aug.
- Aster longioides*, White, October.
- Lilium narthagon coccinea*, Scarlet, July.
- Liatris odorata*, Blue, September.
- Helianthus grandiflorus*, Yellow, July.

- Quelone mexicana*, Red, June.
- Delphinium formosum*, July.
- Trifolium media*, Yellow, October.
- Clematis hybrida*, White, August.
- Espar. pulcherrima*, Red, May.
- Aster multiflorus*, White, Sept.

BACK ROW, 4 feet to 5 feet:

- Chelone barbata coccinea*, Red, July.
- Lilium candidum*, White, June.
- Solidago sempervirens*, Yellow, Sept.
- Aconitum Hilleri*, Blue, June.
- Aster Novi-Belgii rubra*, Red, Sept.
- Epilobium angustifolium album*, White, July.

- 12 plants 3 feet apart.
- Lilium tigrinum*, Yellow, August.
- Delphinium speciosum*, Blue, July.
- Aster precalvus*, Red, October.
- Spiraea barbara*, White, July.
- Hidens procerus*, Yellow, November.
- Liatris elegans*, Blue, Sept.

T. APFLEBY.

HYACINTH AND CAMELLIA SHOW

AT THE ROYAL HORTICULTURAL SOCIETY'S GARDENS.

I AM an admirer of both those flowers, and I am a Fellow of the Society as much from my admiration of florists' flowers as from anything else; and I write to you, therefore, in my own name and in the name of hundreds who wished to see the Hyacinths and Camellias but could not see them, to protest against the exhibitions being held in such a small room as was employed on the 19th. Never was a greater want of judgment shown than on that occasion; and if repeated, joined to other circumstances, it will justify the suspicion that the old influence

still predominates, and that there is less care for floriculture than for botany.—HORTICULTURUS.

[There cannot be two opinions upon the fact that the Council-room employed for the Show was far too small for the purpose; and we will not defend the judgment which decided that such a room was large enough for such an Exhibition—the height of the London season. Much of the inconvenience might have been avoided, had the turnstiles been placed in the grand entrance, and the north door of the Council-room had been opened for admission, leaving the garden front for the exit. We are glad, notwithstanding, that the Show was not displayed in the conservatory, for that is now an exhibition of itself—the semicircular baskets, forming a beautiful crenulated border round the interior, are charmingly furnished, and would have been obscured if the Show had been held there.

The experience of the 19th warns the Council of what must be done—a part of the arcade must be glazed and otherwise fitted up, so as to render it a comfortable and sufficiently extensive site for exhibitions; but with the glazed ends and side so provided with doors as to admit of very ready ingress and egress. We cannot agree with you that there is any disposition on the part of the Council to encourage botany at the expense of floriculture. This Exhibition was itself an evidence to the contrary.—EDS. J. OF H.]

HYACINTHS.

MESSRS. W. CUTBUSH & SON'S, HIGHGATE.

MESSRS. CUTBUSH'S Hyacinth Show is one of the sights of London which all persons who take an interest in flowers ought to visit. This spring the display is even more magnificent than usual, comprising not only a vast collection of the best established sorts, but also a large number of those which are either quite new or less generally known than their merits deserve.

The Exhibition is held in a large lean-to house resembling the letter L in shape, and covered with tiffany, excluding the sun's rays, but admitting an abundance of light. The back wall of the house is entirely concealed by a mass of flowering plants—such as *Camellias*, *Azales*, *Dentzias*, *Heaths*, *Pelargoniums*, *Cinerarias*, &c.; then comes a row of early Tulips, chiefly yellow and scarlet, arranged alternately, but varied by the introduction here and there of other colours; and whilst the base of the stage is occupied by *Roses* in bud, and *Cyclamens*, the whole being edged with *Mignonette*, which communicates a delightful fragrance to the already perfumed air. Hanging at intervals from the roof are wire baskets gay with Tulips and Hyacinths, giving the whole a light and graceful appearance, and serving to relieve the dense mass of plants with which the stage is crowded.

Turning to the other side the eye encounters, springing as it were out of a quiet mossy carpet, three broad ribbons of colour running all round the house, the effect of which when viewed from the farther end is very striking. This is the great feature of the Show, all the rest of the plants being merely introduced to heighten the general effect.

The bloom was in splendid condition, the spikes being almost without exception large and well clothed with bells, and the colours well developed.

Among the *Double Reds*, conspicuous for size and colour were the new sorts, *Koh-i-Noor*, with quite a mass of bells, and *Susannah Maria*, both of which fully justify the high character that they have been reported to possess. These with the Duke of Wellington, which is decidedly the finest of the pale reds, and *Noble par Mérité*, are evidently the best of their class; Milton, with large deep red bells, is likewise an excellent variety; *Regina Victoria*, rose pink, one that is good and distinct.

In *Double Whites*, *La Tour d'Auvergne*, with its large and handsome bells, and *Prince of Waterloo*, here as elsewhere maintain their pre-eminence as the best and purest of their colour; the former variety was, however, not in full perfection. *Sir Bulwer Lytton*, a new kind, has large and very curiously-formed bells, slightly tinged with purple at the eye.

Of the *Double Blues*, *Laurens Koster*, with long dense spikes of dark indigo blue remains the finest of its colour; *Prince of Saxe Weimar* is another excellent dark blue both for size of spike and colour; *Parlboot*, with its peerly blue extremely double bells was particularly fine; and so were *Garrick*, light blue with a broad purple mark down the centre of each petal; and *Sir Colin Campbell*, with large bells of a light shaded blue. *Van Speyk*, with immense very double bells, is another decidedly first-class sort.

In the *Single Reds*, Cavaignac was remarkable for its immense spike and bells, of a salmon colour striped with deep rose; La Dame du Lac, pale rosy pink, was also very good; Lady Sale, deep red; Lina, bright crimson; and Monsieur Fesach, almost scarlet, are excellent; Mrs. Beecher Stowe, with closely-arranged rosy pink bells, is decidedly one of the finest of its class; Princess Charlotte, shaded soft rosy pink, is an improvement on La Dame du Lac, possessing very large bells closely arranged; Macaulay, vivid crimson; and Howard, orange crimson, are new and fine; Princesse Clothilde, another new variety is much in the way of Mrs. Beecher Stowe, with an immense spike about 7 inches in length, and bells of a pale pink striped with crimson carmine, very closely arranged; Pelissier, with large crimson scarlet bells, is also new and fine; Diebitz Sabalkansky and Solfaterre with their brilliantly-coloured flowers, those of the latter with very large bells; Sultan's Favourite, with pink-striped flowers; and Von Schiller, with dense salmon pink bells, were among the gems of the Exhibition. Reine des Javines, crimson; and Victoria Alexandrina, intense crimson, are two new and handsome varieties, the latter decidedly of the first merit.

Single Lilacs.—The best of these were:—Honneur d'Overeen, deep mauve, very close; Prince of Wales, fine mauve, large spike and bells; and Haydn, lilac magenta, very large spike. All three new and first-rate sorts.

In *Single Whites*, among other fine varieties, were Elfrida, a beautiful creamy blush, very handsome and of great substance; Gigantea, deep blush, with faint stripe down the centre of each petal; Grandeur à Merveille, a dense mass of pale blush bells; Madame Van der Hoop, with superb spikes and bells; Mont Blanc, very fine; Orondates; and Tubalora, very handsome, blush, with reddish-purple marks on the tube. But there are two others which, apart from their novelty, are particularly worthy of notice—viz., Miss Burdett Coutts, a beautiful creamy blush of great substance, with bells of altogether extraordinary size—larger, indeed, Mr. Cutbush says, than those of any other white; Hyacinth with which he is acquainted; the other is Snowball, pure white, with very large bells of great substance, and in form almost circular, approaching more closely to the *heavily ideal* of a florist's Hyacinth than any other variety. It, therefore, promises to be the parent of a new race.

Single Blues present less of novelty, though the best sorts are well represented. Argus, with its conspicuous white eye, was very handsome; Baron Von Tuyl; Ben Mourant; Charles Dickens, remarkable for its splendid spikes; Grand Lilas; and Von Humboldt, deep purplish-blue, approaching to black, and therefore, one would imagine, more properly belonging to that class, were all deserving of the highest commendation.

In the *Single Black* class, Blackbird was noticeable as being the darkest of all; General Havelock, with its large and close spike, was well worthy of the hero after whom it is named; La Nuit, deep purplish-black, has a good close spike; and Prince Albert, very dark, is a variety of great excellence.

Single Yellows are not a numerous class, nor are they so attractive as their more brilliant neighbours. Still, exception must be made in favour of Ida, bright yellow, well clothed with bells; and Victor Lingo, of a finer colour than Ida, but not so large. Due de Malakoff, orange, striped with carmine; and Aurora, orange, faintly striped, and having the back of the bells splashed with carmine, are also two very good new varieties.

There were many more varieties of great beauty, and, perhaps, some novelties that escaped our notice, but the above comprise the kinds that appeared most remarkable, either on account of their recent introduction or established merit.

It is only justice to say that the whole Exhibition reflected the greatest credit on the taste and skill of Messrs. Cutbush; and if any one accustomed to the miserable specimens of Hyacinth culture too often to be met with, even in gardens of some pretensions, suspects that we have spoken too highly of the display at Highgate, let him go and judge for himself. Even if he derive no benefit from the example of successful cultivation which will there lie before him, he will at least have tasted a joy that leaves no sting behind.

COCOA-NUT FIBRE REFUSE.—We have now been using cocoa-nut fibre refuse for the last twelve months, and have a ridge of it, some of which has been nearly two years in the heap, and now is in excellent condition for mixing with other mould for potting, &c.—E. G. HENDERSON & SON, Wellington Road Nursery.

TREATMENT OF PEACH TREES IN BLOOM UNDER GLASS.

I AM in a great strait between two garden doctors, who cannot agree respecting the treatment of a Peach tree on the back wall of myinery. The tree, at the present time, is in full blossom from the top to the bottom; and, according to the advice of one of the doctors, I am keeping the roots without a drop of water, and have done so all the winter. He says, should I water, the blossoms will all drop off without setting. Now for the other doctor, who tells me to pursue just the contrary course of treatment—that if I do not water, all my blossoms are doomed, and that I ought to have done so occasionally during the winter months.

Pray assist a poor unfortunate amateur, who, between two stools is sure to come to the ground, besides the mortification of losing all the fruit.—S. S. S.

[You would see the matter referred to last week. If the soil is very dry, and the roots have not gone deep—very undesirable, the bloom will be apt to drop from dryness. We should have given a little at a time, making small holes, as soon as the buds began to swell freely; even now we would advise that course. A great drenching all at once, from the sudden stimulus, would be as dangerous as great dryness. We can see an advantage in such deciduous trees being dryish, not dry, when in a state of rest; but we can see no reason why the soil should be so dry when the trees are in bloom, though we do see reason why the atmosphere should be rather dry then. The trees will not long flourish if destitute of water at the roots; and in this dry state, a great drenching at the roots will be apt to cause the fruit to be pushed off at any time.]

EARLY SPRING FLOWERS.

I HAVE noticed the desire of some of your subscribers to have a list of spring flowers. I enclose a list of those now (March 20th) in bloom in my garden at Wilmslow, near Manchester. Those having an asterisk affixed were in bloom on the 5th of February.

I should be glad to be informed if there be any other flowers which naturally bloom at this season or earlier.

Crocus, yellow*, white, purple, striped; Snowdrop, single*, double; Rhododendron; Erica cinerea; Christmas Rose*; Mezerion Pink, dark red; Andromeda floribunda; Wallflower*; White Alyssum; Pansies*; Hepatica, white, blue, purple*; Grape Hyacinths; Daffodils; Violets; Aubretia alba*, purple; Polyanthus*; Primrose, purple; Cowslip*; Dog-tooth Violet; Bulboecidium vernalis*; Scilla, blue*, white; blue Hyacinth.

Thirty-two sorts in blossom 20th March.—A. CONSTANCE SCHEIBER.

AN EVERGREEN CYCLAMEN.

CYCLAMENS of various kinds, colours, and characters, of late have been described through the pages of my weekly companion, THE COTTAGE GARDENER—the old title like old friends, hard to call them by another name. However, it is the name I want, and to increase my Cyclamen which has been in my possession three years. Its greatest curiosity is, that it has been in bloom more or less for the last two years and six months, reminding me of an inscription I once saw on a tombstone—viz., "Say what a wife ought to be, and she was that." Say what a Cyclamen ought to be, and mine is that, always growing and blooming. Well, to describe it as near as I can. Its roots I cannot say anything positively about, for I made no memorandum of them when I received it from the hands of my worthy and present employer. The bulb was sound and fresh, of a dark brown colour, about the size of a walnut, but reminding me at the time of being a peculiar shape—neither round nor yet oval, but a one-sided oval. However, after potting and several weeks' anxious attention it started into growth, apparently two leaves coming from one side of the bulb, but to my surprise it was a leaf and a flower hand-in-hand together, and so it has continued to this day, with the exception of the flowers: when withered they gradually decay down to the gouty stem, which is more than an inch high. The leaves remain on for a whole season. The flower in size is midway between the Cyclamen persicum and coum; petals broad, and of a rose pink, with a dark purple base; scent delicious; flower-stems slender and of an average

length of 5 inches; young leaves slightly toothed, of a pea-green colour, with a beautiful marbled-like mark; under side of the leaf is a most beautiful reddish-purple, when full grown 1½ inch in diameter and heart-shaped; leafstalks slender and 2 inches in length, and when fully developed hang below the level of the gony stem from whence they spring. It has also made a second stem from the base of the first, growing at present horizontal, producing a leaf and a flower as in the first. The reason why I have not made inquiries before is, I do not like to give up until I am fairly beaten; and not always then; but I must in this case, for I have tried every bloom, and a pod of seed I cannot get. The side shoots I am afraid to take off, and being anxious to increase it if Mr. Benton will be my legal adviser it will be gratefully received and oblige—J. HOLLAND.

P.S.—I may state the plant is in beautiful health, having thirteen leaves, three flowers, and several coming, but I am very reluctant to cut a leaf or flower. Living so handy the whole may be seen, otherwise I would have sent both leaf and flower.

[This is, in fact, an evergreen Cyclamen. It was exhibited at South Kensington by Mr. Holland, a well-known exhibitor and successful raiser of superior crosses of popular flowers, and I had it in my hands to smell. A Violet is not sweeter. The plant has the same kind of spur as verum, and as the crocuspium which the gentlemen dug up in Savoy and sent me one, and also like my verum. It is making a side-spur at the side of the tuber. But what is it? It is not described in any book I know, and I had a walking encyclopedia the other day by the button-hole—Mr. Gordon, who grew them all at Chiswick for years, and also described them with all their aliases better than any one else. Yet he does not know this kind. Mr. Holland is a splendid grower of Cyclamens. I never saw such leaves of them as he sent to the Show, and we both agreed that any kind of them which is difficult to seed ought to be treated like the Chinese Primrose for the same purpose.—D. BEATON.]

NEW BOOKS.

The Ailanthus Silkworm and the Ailanthus Tree, by LADY DOROTHY NEVILL. London: "JOURNAL OF HORTICULTURE" Office, 162, Fleet Street.

THERE is no one in this country who understands the habits and management of the new Chinese Silkworm so well as Lady Dorothy Nevill, whose book on the subject is now before us. Unlike the true Silkworm (*Bombyx mori*) this new species is extremely hardy, and has been found to succeed perfectly out of doors, without anything more than ordinary care being given to the worms. They may be turned out to pasture, as it were, on the Ailanthus trees without perishing by the vicissitudes of our climate, or being carried off by the rapacity of birds, as is the case with the other species. That the rearing of these worms will become a favourite occupation among us there cannot be a doubt; for, besides the mere fact of their producing an abundance of silk, the moths themselves are so large and beautiful as to make them an object of attraction. The way in which Lady Dorothy has performed the task she has assigned herself is most meritorious; and as she writes entirely from experience, and as confirming the experience of some of the most extensive breeders of these worms in France where they are produced very extensively, the greatest reliance is to be placed on the information her ladyship communicates.

A Supplement to "Gordon's Pinetum," containing descriptions and additional Synonymes of all the Coniferous Plants not enumerated in that work, with corrections up to the present time, by GEORGE GORDON, A.L.S. London: Henry G. Bohn.

If the appearance of the "Pinetum" itself was welcome, that of the Supplement is equally so. Before Mr. Gordon published that which has proved so valuable a text-book, both to country gentlemen and to nurserymen, there was no work in the English language which had been specially devoted to the subject of Conifers. For four years it has now been in the hands of the public, and we may safely say there are few who have had occasion to consult its pages who would willingly be deprived of the privilege of doing so. Since its publication, however, many new Conifers have been discovered and introduced, many reputed distinct species have been proved to be synonymous with others previously described, and misconceptions regarding others have been ascertained. All these, and much more, have been introduced into the Supplement, and we have now a very useful

and valuable addition to our knowledge of this beautiful family. Mr. Gordon has done good service by reducing those fanciful species of Pinus which Roelz sent from Mexico to their proper places. Nor does he confine himself to botanical matters alone, but throughout the work we meet with much that is of a popular character, as for instance, the following remarks on the Araucaria imbricata:—

"Dr. Peppig says, such is the extent of the Araucaria forest, on the Chilean Andes, and the amazing quantity of nutritious seeds that each full-grown tree produces, that the Indians are ever scarce from want; it yielding to those warlike nations a vegetable substance, that is found in greatest plenty the more they recede from the whites. The kernels are dried after being boiled, for winter use; their time of ripening being towards the end of March, at which time the cones break up and fall to pieces, shedding their seeds on the ground, and thus bestowing a great boon on the poor Indians, which nothing but a small parrot divides with them. The Araucarians eat the nuts either fresh, boiled, or roasted, and distil from them a kind of spirituous liquor, and prepare a kind of flour and pastry from them, or dry them for winter store, and for trading to Valparaiso or Lima, where large quantities are consumed annually by the people. And there is but little doubt when the numerous young Araucarias which are now planting, or have been planted in Europe, become large, and arrive at a fruit-bearing state, but that as great a boon will be given to future generations as that conferred on the present one by the fruit of the Spanish Chestnut, which is now so largely consumed in all the towns and cities of Europe.

"The Chili Pine was first introduced into England by Mr. Munzies, in 1795, and presented to Sir Joseph Banks, who planted one of the first plants at his residence, Spring Grove, near Hounslow, and sent the others to the Royal Gardens at Kew; and from which circumstance it formerly was called Sir Joseph Banks' Pine."

This is a work which must be in the hands of every lover of Conifers.

THE BIRMINGHAM ROSE SHOW.

A MEETING of gentlemen desirous of establishing an annual Exhibition of Roses in Birmingham, open to all England, was held in the Committee-room of the Town Hall on the 13th of March. The Mayor (H. Manton, Esq.), presided, and there were also present the Rev. P. M. Smythe (the Solihull), Messrs. T. B. Wright, John Lowe, C. L. Browning, F. Walton (St. Cuthbert's, Altrington), G. P. Tye, J. Cole, James Clements, J. B. Gausby, J. Cranston, J. T. Brown, jun., B. A. Hallam, and E. W. Badger.

The Mayor having briefly opened the proceedings, Mr. E. W. Badger, one of the Hon. Secretaries, read letters from Mr. Thomas Rivers, Sawbridgeworth; the Rev. C. H. Bulmer, Credenhill Rectory, Herefordshire; Mr. Richard Smith, and Mr. Archibald Wood, of Worcester; Messrs. James Dixon and Sons, Newton Nurseries, Chester; Mr. Samuel Evans, of Arbury (C. N. Newdegate, Esq., M.P.'s head gardener); Mr. Charles Kimberley, of Stoke, near Coventry; Mr. Charles Turner, Royal Nurseries, Slough; Mr. William Paul, Waltham Cross; Mr. John Cranston, King's Acre, Hereford; and Mr. C. J. Perry; all of whom sympathised heartily with the movement, and expressed their regret that they could not attend. Mr. Badger also read extracts from two letters from the Rev. S. Reynolds Hole, Causton Manor, Newark, the founder of the National Rose Show, in which that gentleman intimated that he would gladly afford to the Committee the experience he had gained from the superintendence of the great metropolitan shows. He also stated, in reference to an advertisement he had published inviting communications from persons interested in the establishment of a Midland or Northern Counties Rose Show, that at that time he was unaware of the projected Birmingham Show; but now, being quite convinced that two Midland Shows were unnecessary, he should propose to all his midland friends to join him in co-operating with the promoters of the Show at Birmingham. He, however, added that he should take steps to establish a Northern Rose Show, and then all Rose-growers in England would have ample opportunities afforded them of showing or seeing the queen of flowers in her beauty.

Finally it was resolved,

"That this Meeting cordially approves of the proposal which has been made to establish in Birmingham an annual Exhibition of Roses, and of Garden Ornaments, and of Horticultural Tools, open to all England, and is prepared to afford its co-operation in whatever may be necessary to promote the success of such Exhibition."

"That in order to carry out the foregoing resolution, the following gentlemen (about sixty) be and are hereby appointed a Committee of Management for the present year, with power to add to their number, and to fix the time for holding the said Exhibition; to prepare and circulate a prize list and regulations, and generally to conduct the business of the Show; and that the Mayor of Birmingham be the Chairman of the Committee, and Mr. T. B. Wright, Vice-Chairman.

"That Mr. John Cole be respectfully requested to accept the office of Treasurer for the present year."

"That Mr. B. A. Hallam and Mr. E. W. Badger be respectfully requested to act as the Honorary Secretaries for the present year." a

GREENHOUSE WITH WET SOIL.

A CONSTANT run of water, though carefully carried off by drain-pipes under the floor of my greenhouse, causes such a supply of moisture when evaporated by fire heat, as to render the sash-frames mouldy. At present the ground is covered with a good layer of coal ashes, constituting the whole flooring, except the path, which is tiled.

Can you tell me how to prevent the excessive rise of moisture? Would the end be attained by covering the coal ashes with a concrete made, say, of one part Portland cement, and three parts gravel? I am not sure if this would be perfectly waterproof. Any mixture with tar would make an intolerable smell. I find woodlice abundant in the ashes of the floor. Can I destroy them and prevent their reproduction by a good watering with a solution of sulphate of zinc or other strong poison?—M. H.

We think your best plan would be to make the joints of your drain-pipes secure with Portland cement, or, if a barrel drain, to cover that with the same. We have a strong suspicion that the mouldiness of the sash-frames is more the result of want of air in dull weather than the mere evaporation of water from the drain, and we come to this conclusion from so many woodlice being among the ashes, as they do not like a damp place by any means. We think your saturating the ashes with any liquid, poisonous or otherwise, would increase the moisture in the atmosphere of the house, and would not kill the woodlice. If you did so water, and left a part of the sides dry, and put a little dry hay along there, you might pour boiling water on them on moving the hay in the morning. You could make a floor impenetrable to water by laying down 3 inches of concrete made as lately described in "Doings of Last Week," leaving the surface a little rough, and then covering smooth with half an inch of Portland cement, with nearly as much of clean, rough sand mixed with it as it was laid down. But though we do not think any damp would rise through such a floor, neither do we think that any would go down through it, but that every drop of water spilled would remain. As said at first, a little more heat and more air would cure what you complain of. The glass of all cool houses needs washing at times.]

THE CHALLENGE ACCEPTED.

I ACQUIT "A NURSERYMAN'S" acceptance of my challenge. But I should have done so with the greater thankfulness if he had offered to send me Madame Turfado, and five more new Roses just as good as Madame, if there are so many of that style and stamp in his catalogue. Then, if I had to submit to having my head shaved, such Roses would pay me for the crop. As it is, two good, healthy, vigorous Pontic Rhododendrons will be quite sufficient, each of them must have at least four shoots of last summer's growth, not less than one foot long each. After disbudding the four shoots or more, I shall give one of the plants to Mr. Eyles to prove, and keep the other one myself. When I lost the Experimental Garden, my mantle, by common consent, fell to Mr. Eyles' lot, and I know of no one who is more likely to do what is just and proper for both the challenger and "A NURSERYMAN." Then, if I lose my crop, I shall prove the chaff—prove if Rhododendrons will grow twice as much in the cocoa-nut refuse as in peat, and I shall know more to the bargain than any physiologist in Europe could tell me now.—D. BEATON.

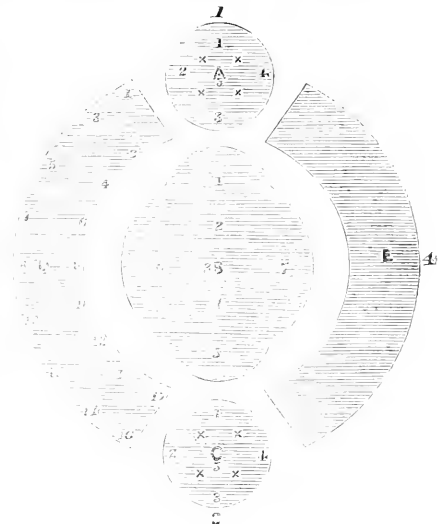

SPIREAS IN GEOMETRIC BEDS.

UNTIL I saw the Spiræas here, I had no conception that they could be clumped in such effective masses, and made to break a flat surface with so charming a result, and my master tells me he derived the original idea from the paper on Spiræas in your Number for February 27th, 1851.

I enclose you a plan of beds designed to give full effect to the contrasting colours and habits of growth of the several shrubby Spiræas, which have attained here the height of 4 feet and 5 feet in many cases, and produce a fine, bold break in the flat parterres around the clumps. I purpose this year edging these clumps with Scarlet Geraniums and Pentstemons.

We have here more than two hundred dwarf standard Apple trees of all the best kinds, never exceeding 7 feet in height, and pruned close. They bear in good seasons about four score of Apples each tree. They all are planted 4 feet from the Box-edge of the kitchen-garden walks with a single row of the different sorts of Strawberries, at 1 foot inside the Box-edging

along every path; and thus, whilst the heavy sea-side winds here do not blow off our fruit, both Apples and Strawberries are picked without walking over the vegetable-beds, and this plan further gives diversity to the aspect of the flat area of the circumjacent garden.—T. VICKARY, *The Pavilion, Aldwick.*

a. Five Spiræa bella, rose-coloured flowers.

b. 1, 3, 5, Spiræa nitida. 2, 4, 6, 7, Spiræa arifolia.

c. Five Spiræa salicifolia, pink flowers.

d and e beds planted quinque-ax-fashion with equal proportions of the pink and white Spiræas, chinensis, sibirica, Lindleyana, Lindleyana, Lindleyana, and others of the same class of plant, and all are copifolia, incarnata, and others of the same class of plant, and all are beautiful either in leaf or flower, mass well, and stand well in exposed places, with the great advantage of coming early into leaf also, until they assume a somewhat large, bushy form. The angles between the Spiræas can be filled-in with two-feet-high plants of that hardy Fuchsia the Riccartoni, of which we have hedges formed here bordering our walks, and which we do not cut down even in winter.

d. TAIL MEASUREMENTS OF ABOVE DESIGN.—From 1 to 2, longitudinally, 70 feet, and from 3 to 4, transversely, 50 feet. The circular beds, a, c are each 16 feet in diameter, and the oval-shaped central bed, n, is 36 feet long by 26 feet broad, whilst the broader gravel walk round the centre bed is 4 feet wide, and the others 2 feet wide, exclusive of the Box-edging in each case, which surrounds all the beds, 4 inches high, and bushy throughout.

[This idea is so good that we have had the plan of it engraved. But there is an error of principle in the planting which might easily be altered in the present garden, and avoided in another. The idea is that of planting Spiræas in masses—say the best flowering ones. Since the Linnean system of arranging plants has been superseded, massing particular families of plants has been done on the natural system. So called then, on the natural system Spiræa serbifolia, and S. Lindleyana, should not be planted along with any other species of the genus, because they break the natural resemblance of the rest, the one from the other, and so the effect of natural affinity is neutralised. The Sorb-like Spiræas should never, therefore, be planted with a mass of other Spiræas, being as different in their looks as Larches are from the Ash. We would advise that Spiræa callosa and Nobleana should be substituted for serbifolia and Lindleyana. From what Mr. Beaton has written to us about the bedding of Spiræas at Kew, and of the appearance of various forms of Spiræa Nobleana from seeds there, we should be inclined to look for improved sorts of that family from the seeds when masses of the best of them are grown together as has been done in this instance. Where Fuchsia Riccartoni makes permanent hedges like the nine-feet-high hedges of it which we once heard of near Belfast, the seeds of Spiræa would surely ripen. Yet, when the Spiræas are out of bloom the two referred to are the best-looking of the family, and we have pointed out long since the desirability of having short standards of Lindleyana.]

A FEW DAYS IN IRELAND.—No. 18.

ROCKVILLE, BLACKROCK, DUBLIN.

(Continued from page 502.)

WE now come to the orchard-house, which, however, is supplied with enough of piping to keep out frost, and therefore might more properly be called a fruit-house. It is one of the finest things of the kind that have sprung from Mr. Rivers' writings and practice; it is a very substantial as well as elegant affair, and is 84 feet long by 60 feet wide, the roof being formed of three spans, of which the centre is the highest, and the slope on the outside on each side longer by 3 feet or so than the others. The dotted lines in the section, p. 477, will represent the orchard-house without showing the furrow-plates, and the heavy lines will represent a section of the Fern-house. The height to the central ridge of the fruit-house from the floor level is 16½ feet, to the side ridges 15 feet, to the furrow-plates 10 feet, outside between 8½ feet and 9 feet; and as the paths are sunk 2 feet below the ground level, the glass that comes down on the sides to the ground level will, after allowing for sill and wall-plate, be from 6 feet to 7 feet in height. There are sashes hung on pivots at the centre, and all movable, so as to give abundance of air. The outside border was previously described. Air is also given at the ridge by ventilators 5 feet long and 1 foot deep, hinged to the ridge-board, and opened and shut with line and pulley. The sides and roofs of both houses are divided into bays by studs and rafters of wood 6 feet apart; and between these, iron sash-bars are placed, and Mr. O'Brien for such structures prefers this combination to either material alone. The space inside is divided by four pathways 3 feet wide into five unequal beds; one close to each side, 1 foot wide, 2 feet above the pathway, and therefore of the same height as the ground level outside, down to which the glass comes. The beds under the two side spans are 11 feet wide, and the central bed is 18 feet wide. These three beds are scarcely a foot above the pathways. They were chiefly supplied in September with Peaches and Nectarines in the open bush style, standing some 12 feet apart, and ranging from a little less to a little more than 10 feet in diameter of head, and 10 feet in height. These were planted out in what might be termed strong batted baskets, with stout slabs at the bottom to prevent the roots getting down; and every year, or every other year, the roots could be pruned outside the battens when the growth became too vigorous. The trees seemed to be vigorous enough, and well stored with wood nearly ripe, and the buds strong and prominent. A great number of fruit trees could be accommodated besides these Peach trees in this house, which we presume were then out of doors; but the house was rendered gay with orange trees, large Scarlet Geraniums in pots, and a number of the finer and more tender Conifers. Vines were also planted alongside the borders at the ends, to be grown a good deal in the vineyard or Raspberry style. We

forget now if planted in the centre of the house, but we thought a few connected arches, either transversely or longitudinally, or both, with Grapes hanging from them, would be a good feature, and if done only thinly would not interfere much with the light necessary for the mass of plants in the beds. Perhaps such an arrangement, however, might lessen the surprise which every visitor must feel on entering the Fern-house. The quantity of Strawberries obtained from such a house must be something wonderful. A little below each furrow-plate are two shelves—one on each side, another at each side in front, and, we think, one above the path at raised border at the sides, and then one at each end, making, we presume, ten across the house besides the ends, and thus furnishing from nine hundred to a thousand feet of shelves for Strawberries. The shelves seemed to form part of the building, were about 7 inches wide and 1 inch deep, or a little more; and whilst the outside was nicely painted, the inside was well pitched so as to retain water. With so much light and air, and not far from the glass withal, and also, we presume, not being forced very early, we can well suppose that the clusters that hang from the shelves will be magnificent.

FERNERY.

The only outside distinctions between the orchard-house and fernery (the roof being spanned and finished the same way), are that the fernery, though the same width, is shorter by 25 feet or so; the roof is higher by 2 feet; and the floor being 18 inches lower, the height from the floor is 3½ feet more than the orchard-house. This makes the height to the ridge of the centre span 20 feet, side spans 18 feet 6 inches, furrow-plates 13½ feet, and side-wall plates from the longer slopes 12½ feet. Again, this 12½ feet has fully 6 feet of brick-wall, and in this sliding ventilators are placed, the ground being naturally lower here than at the orchard-house. The glass above the brick and all the roof except the ventilators at the ridge are fixed. There is, besides these great essential differences, a double glass roof; the outer one for each slope of the span being divided into two lights, fastened to the rafters, &c., by thumb-screws about 4½ inches above the lower fixed roof, so that one or all the lights may be moved at any time. On the upper half or light a piece of hoop iron is screwed, beneath which the lower light slips, so to prevent any wet getting between the roofs. The enclosed body of air will so far act as a nonconductor, and thus secure an equable, temperate, enjoyable atmosphere inside the house. We have frequently recommended such roofs, though our own experience has been rather limited, but that sufficiently told in their favour. Where high temperatures are wanted in spring and winter, the expense of the extra glass would soon be saved in coals, and

besides, even in low positions and frames, there would be no necessity of covering and risking glass-breaking: we were, therefore, delighted to find Mr. O'Brien recommending them so highly. No doubt they will become much more general, and most likely old Ireland, now so thoroughly resolved to go ahead, will take the lead in the race. Mr. O'Brien is confident that his double roof in general makes a difference of temperature of from 12° to 15°—a mighty difference for an enjoyable house under a keen frost at Christmas and a broiling sun at midsummer. And once more as respects the roof. At our visit the sides and roof were muffled, and various tufts seemed to be on trial. Now, all the inside glass of the roof is muffled of a wine-red colour, and the warm and cheerful look it gives inside, and the tinge the plants receive renders it surprisingly effective. We are yet in our pupillage as to the influence of tinted glass; but we can well believe the striking effects thus produced. We were privileged twice to see a great lady's boudoir. The walls were covered with white-dressed satin, and rich ornaments in addition. On a summer day it looked so chaste and cool! On another summer day with a bright sun the windows were shaded with bright pink muslin curtains. The effect was magical, almost overpowering; the flowers of the satin seemed to stand out in bold relief, and one felt as if he were moving in an atmosphere of crimson and gold!

Having thus glanced at the peculiarities of the outside of the house, we pass the door in the glass partition that separates it from the fruit-house, and step down on its floor of clean shingle. And what a surprise! The idea is at once impressed that you have suddenly come on the ruins of a once sacred fane, over which, now deserted alike by priest and devotee, vegetation is gradually but surely exercising unbroken dominion. Massive buttresses from which spring pointed Gothic arches, 12 feet from centre to centre, and 12 feet from floor to point of arch, throw the main part of the house into a central and two side aisles. These buttresses and arches are built of thick greyish-brown late stone brought from the lead mines. We presume they are cemented near the centre, as the joints outside are mostly open, not only thus keeping up the idea of hoary age, and the wasting effects of time, in a structure but of yesterday, as it were, but furnishing no end of places where Mosses and Ferns may find a comfortable home. From the springing of the arch to the coping, many large places and openings are left in which drooping Ferns and Mosses will grow freely and strongly. Many Begonias with fine foliage had been planted in such buttresses, flourishing all the better from their fleshy rhizomes being somewhat squeezed by the stones or slates. The colour of the leaves was also more vivid than usual, and the double muffled roof prevented any such a thing as a spot or a crawly to mar the effect. Many of the Adiantums, including the native *capillus-Veneris*, &c., along with drooping Ferns from the arches, and Chinese and other Bamboos at the base of the buttresses, along with Mosses, &c., were giving the buttresses and arches such a finished appearance, as to show that ere long great taste will be required, not so much in giving a vegetable covering of the most beautiful in form and character, but in so regulating it as to allow the stonework to be seen. Though the house is intended to be kept merely temperate, and, therefore, thoroughly enjoyable, not only will the smaller and more tender of British, Irish, and North American Ferns have a chance of flourishing thoroughly, but all except the very tenderest of tropical kinds will manage to live and thrive, as it is well known that many that are usually kept in a stove will stand a good amount of cold uninjured.

Whilst the buttresses are thus decorated, the open spaces of the aisles are now chiefly occupied by large plants with fine foliage, mostly panted, or seeming to be so, in little mounds of rockwork. The following are some of the most striking that thus placed singly cannot fail to command attention:—A noble plant of *Latania borbonica*, with its beautifully plaited fan-like leaves; a noble plant of *Dicksonia antarctica*, 10½ feet in height to top of fronds, fine, dark, clear stem 3 feet in circumference, and the fronds forming a circle 12 feet in diameter; *Dicksonia squarrosa*, true, 11½ feet in height, with noble fronds, and feathered with offsets all up the stem; *Alophila australis*, 10 feet in height, with an elegant crown of healthy fronds; *Alophila excelsa*, 11 feet in height, with noble foliage. Then there were fine large plants of *Cyathea dealbata*, *Cyathea medullaris*, *Alophila Macartneii*, *Rhopala De Jonghii*, and the beautiful *Lasia leptophylla* and *papyrifera*; also good plants of the singular-leaved *Dammaras* from New Caledonia; *Draecena nutans*; *Imatophyllum minutum*, 12 feet in circumference; a

Chinese *Colefoot*, *Tarfugium grande*, 20 feet in circumference; and a noble specimen of the India-rubber plant, which with its thick, leathery leaves contrasted strongly with the leathery foliage by which it was surrounded.

If criticism here would dare intrude, it would be to the effect, that the shingle on the floor was rather bright, and the fine plants in the aisles just regular enough to be in general keeping with the leading idea—a fault, if fault it be, which will soon be removed as the principal plants grow, and Ferns and Mosses break in upon and take away everything like symmetry of outline in the pathways.

Two four-inch hot-water pipes go right round by the sides of the house, so that, for such a large place, will show it is not intended to use much heat, and yet we are convinced that not only Australian tree Ferns, but Palms will flourish in it. There were platforms at the sides on our visit, but Mr. O'Brien kindly told us how he intended having an irregular rockwork there as well as at the entrance end, and since then the design has been carried out. Between the wall a small opening is left to allow air to rise from the ventilators in the wall already referred to, and the rockwork itself being constructed over a series of rough arches and caverns, &c., over the heating pipes, the air is not only kept gently in motion, but in cold weather it is heated before passing into the house. From the double roof, however, and the great size of the house, no great rushes of air at any time are necessary, and all changes of temperature are effected very slowly and gradually.

One feature more, which has been before our eyes all this time, though unfortunately the pen can only dot down one set of ideas at the same time. The north end of the house is a solid wall, and in front of it is a fine, massive, irregular specimen of rockwork, formed of different materials, but each by itself, and thus on a limited scale furnishing materials for geological study. These, so far as we recollect, were *Ballycensus* clay slate, red granite, grey granite, quartz, red sandstone, conglomerate, tufa, petrified moss, &c. The lower part of the pile is not only irregular, but formed into arched vaults, caves, recesses, nooks, and crannies, to suit some sweet little things that modestly like retirement from the glare of bright sunlight, as the varieties of Killarney Fern, and some other of the *Trichomanes*, and such *Hymenophyllums* as *Trumbidgeae* and *Wilsoni*, and other small Ferns and Lycopods. Then on the face of the rock were fine specimens of *Platycentrus*, good foliage of *Begonias*; and among other Ferns and Mosses, we had a vivid recollection of a *Platycloma* throwing its elegant fronds over red granite. Steps, rude as they ought to be, take you from either side over the top of this rockwork, revealing some rarity and beauty at your feet at every step mull, reaching the top and surveying the whole—the wreathed buttresses, the draped arches, and the expanse of the fine foliage of tree Ferns, &c., beneath your eye, you might easily imagine you were standing amid the ruins of the buildings of a forgotten race, such as are to be found in central America, where vegetation in wild melancholy grandeur is revelling amid, and obliterating the evidences of a previous power, genius, and civilisation.

Outside once more on the lawn, the least we can do is to express our obligation to Mr. O'Brien for his kind courtesy; our best thanks to Mrs. Bewley for sending through him a view of the fernery, which will give a certain but very imperfect idea of its romantic interest; and our more than thanks to Mr. Bewley, not only for what he has accomplished, but for the great liberality with which he permits these doings to be seen by all the lovers of the rare and the beautiful. We need scarcely express the hope, because certain it is already realised, that his own happiness will be increased in knowing that he is adding to the happiness, the knowledge, and improvement of visitors. These visitors will be numerous, no doubt, if it be true what was written the other day by a friend in Ireland—“It is, as you said, that fernery was worth going a hundred miles to see in the middle of September, it is worth worth going a thousand miles to see now.”

P.S.—After folding-up the above we received a note from Mr. O'Brien in answer to a request that he would mention a few of the rarest plants, and new ones received since our visit; and the following, not mentioning those already referred to, are what he notices, the list of which may be interesting to many readers.

Fraxifolium Planifolium.—*Peridophyllum ceylonicum*, with fine leaves resembling *Pteris umbrosa*; *Cyperus alternifolius* variegatus, very ornamental plant.

Amongst *Loasas* as very rare—*Arthrobotrya*, already referred

to, *Cibotium princeps*, *Alsophila Cooperi*, *Rhipidopteris peltata*, *Selaginella elegans*, *Platynerium Walllichii*, *Trichomanes esxiatum*, *T. trichoides*, *Ac. Gynogramma Witenhalliana*, *G. Lanciana*.

Amongst *New Plants*—*Oncidium sarodes*, fine; *Dendrobium Lowii*; *D. Devonianum grandiflorum*, a fine variety; *Cypripedium Schinerii*, very rare. He also mentions *Phalanopsis Schilleriana*, is as sweet-scented as *Vanda sarraris*, which has not been previously or sufficiently noticed. Also that they have got a distinct and superior variety of *Alcacia metallica*, the leaves being more corlate and much darker, worthy of the slix "superba;" and in fine that the *Eucharis amazonica* should not be confined to a small pot. We have them with a dozen of spikes and above forty flowers open at a time on a single plant, and it is scarcely ever out of bloom.

The fresh importations have been—20 *Oncidium Lancianum*, a fine variety, which throws flower-stems from almost every leaf; 300 *Epidendrum bicoloratum* major, which will thrive only on a block; 200 *Zygopetalum rostratum*, beautiful and rare; and 500 *Ionopsis pycnantha*, beautiful and rare, and in bloom all the year round.

We believe the little Fern-houses are on the north instead of the south of the Orchid-house. In the course of four months we get confused as to positions.

In the plan at page 499, for "kitchen garden," read "reserve garden;" and at page 501, second col., twenty-first line from bottom, for "Lycopodiums," read "Lygodiumis." R. FISL.

USE OF FLAX REFUSE.

I SHOULD have supposed that scutch or skimp as it is called in some places—*i. e.*, the refuse in dressing flax, would have been quite as useful as refuse cocoa-nut fibre, and yet experienced farmers here make no use of it. Pray ventilate the question.—ANOTHER CLERGYMAN BELOW BRISTOL.

[We are not sufficiently acquainted with the scutch or refuse obtained by retting flax to be able to give an opinion upon the question, whether it is likely to answer the same as cocoa-nut fibre refuse as a soil for Ferns, &c. Our correspondent writes as if he thought the refuse of the cocoa-nut fibre is a "fibre;" but it is not so, but a blown powder more like brown rapeseed stuff than anything we can compare it to, unless it be mahogany sawdust. The farmers of the Vale of Taunton do not use the flax refuse as a manure, probably because from the slowness with which it decays its benefit is not promptly visible. "Flax and

hemp refuse," says M. Sprengel, "possesses as much and even more carbon than pea and bean straw; still it yields a much worse manure, which is to be attributed to a want of nitrogen. It yields humic acid very slowly, and the decomposition is very difficult on account of its being composed chiefly of woody fibre." The slowness with which it decomposes renders it a durable manure, and its fertilising power would be discernible, probably, more on the second and third crops than on the first after its application.

Besides the carbon that the flax refuse contains, it has among its constituents five per cent. of the following mineral substances, all contained also by our cultivated crops:—potash, soda, lime, magnesia, alumina, oxide of iron, phosphoric acid, sulphuric acid, chlorine, and silica.

It deserves special notice that when the flax is steeped in water, as usual in preparing it for the flax-mill, much of the saline matter is extracted from the flax by the water. Sir Robert Kane found that besides much decomposing matter, that the water had extracted chloride of potassium, sulphate of potash, carbonate of potash, carbonate of soda, phosphate of iron and alumina, phosphate of lime, carbonate of lime, carbonate of magnesia and silica. This steep-water is really a liquid manure, and we find the following testimony published by Mr. J. Dixon of the British flax-mills.

"I used the water in which I had flax steeped as a manure for flowers. I followed up the experiment; and although I was from home for five weeks, during which time none of the plants had been watered with the flax-steep, still I am able to say that those Dahlias to which I used the water early continued to keep ahead of those not so treated. The latter grew from 23 feet to 3 feet high, while those to which steep-water was applied grew from 7 feet to 8 feet high, when three of them broke down, the sticks being too weak to support them against the wind; but their beauty, from the abundance of bloom, surpassed anything that I have seen. I did not manure my garden for four years, being determined to keep it poor, in order to try what effect flax-water would have in producing good full-grown flowers in cold worn-out soil. I am now able to assert that none of my neighbours had such a blow of Roses or Dahlias as I have had; and to them I can refer, as they were witnesses of the fact. I had, by the use of flax-water, Dahlias from 10 feet to 12 feet high, loaded with the most perfect flowers. This rich liquid manure (for it deserves the name) will be found invaluable to market gardeners and growers of flowers. I find it to annihilate the green fly."]

SUCCESSFUL EXPERIMENTS WITH COCA-NUT FIBRE REFUSE.

COCOA-NUT fibre refuse is a first-rate material for growing Ferns, Orange trees, Gloxinias, Camellias, Azaleas, and Begonias. I was induced to give it a trial about this time last year through what was said in THE JOURNAL OF HORTICULTURE in its favour.

Now, not having a very good opinion of applying vegetable refuse, particularly woody fibre, to the soil, owing to experience telling me that woody fibre in the soil frequently is a step in the path towards making a healthy tree become diseased at the root (it causes that injury by engendering various fungi that frequently harbour on old wood, and accompany or hasten vegetable decomposition). For that reason I thought

I would be cautious and try that wonderful stuff on a small scale.

Well, a cartload was procured of the renovating refuse, and twelve plants of an equal size were chosen for the Fern experiment. Six were potted in the usual Fern compost—*viz.*, one-half turfy peat, one-quarter loam, and one-quarter silver sand. The other six were potted in the refuse. For *Gymnogrammas* the refuse that passed through a half-inch riddle was used for potting, and the same for *Nothochloas*; but for *Asplenium* the refuse was used in its rough state. The following table will show at a glance the results:—

Name of Fern.	Size of plants at potting.			Size of pot for refuse.	Size of pot for Fern compost.			Size of plants after six months' growth in refuse.			Size of plants after six months' growth in Fern compost.		
	In height.	In diameter.	Number of fronds.		In height.	In diameter.	Number of fronds.	In height.	In diameter.	Number of fronds.	In height.	In diameter.	Number of fronds.
ASPLENIUM diversifolium	0 10	1 1	4	0 6	1 1	0 7	0 10	2 3	2 9	9	1 6	1 10	7
ASPLENIUM Belongeri	0 8	1 0	12	0 6	1 0	0 6	0 9	1 2	2 6	33	0 10	1 8	27
Gymnogramma chrysophylla	0 9	0 10	7	0 5	0 11	0 5	0 8	1 8	2 3	23	1 2	1 11	24
Gymnogramma ochracea	1 3	0 11	8	0 4	1 1	0 6	0 9	2 1	3 1	36	1 10	2 3	28
Gymnogramma pulchella	1 2	0 10	6	0 4	1 1	0 5	0 10	2 8	2 6	19	2 1	1 11	17
Nothochloa zeyva	0 7	0 8	5	1 2	0 9	0 5	0 6	0 9	1 3	21	0 8	0 10	18

They were grown in a small house (20 feet by 16 feet), and all had the same treatment; but those in the refuse required twice the quantity of water those in the Fern compost needed. The temperature ranged from 50° to 80°, and a hygrometer indicated from 85° to 91° of atmospheric moisture or humidity.

Unfortunately the bursting of a fine which heated the house brought trouble. *Gymnogrammas* (*chrysophylla* was killed outright), and *Nothochloas* in the Fern compost were sent to the rubbish-heap; but those in the refuse showing signs of life were preserved and are doing well. *A-pleniums* were not injured by the smoke and gases to a serious extent.

Why should those in the refuse stand smoke better than those in peat, &c.? That puzzles and makes me feel anxious to know the reason.

Moreover, the refuse was tried in another way. Half loam and half refuse, with a little sand but no peat, which raised *Pteris argyrea* 2 feet high and as much through within eight months, into a plant 5 feet 6 inches high, and 5 feet in diameter. Also, a *Drynaria morbillosa*, 4 feet across, with six fronds, was potted with the refuse compost, and the same plant is now 12 feet in diameter. Again, a plant of *Davallia polyantha*, with twelve fronds, and the plant 2 feet in diameter, was treated to a pot full of refuse, the pot 1 foot 6 inches in diameter. Well, it is at present 5 feet in diameter and very strong.

Then, again, an Orange tree last March had thought proper to become deciduous, evidently a hopeless case for the physician. Bad treatment had, no doubt, been the cause of its cutting such a miserable figure; but, never mind, cocoa-nut refuse is just the thing to help a poor fellow with a lame leg over a six-barred gate. It makes 'em go whether they will or no.

Now, that Orange tree was potted in a compost of half refuse and turfy loam. It was put in a twelve-inch pot, and about May-day it began to shoot, and made during the summer ample growth, so as to be nicely green all over, and it has kept its leaves this winter, though treated precisely as it had been previously. Upon that very tree are two hundred blossom-buds ready to unfold, and more swelling. What a contrast between last year and this! Last year no leaves, no bloom ready to expand, everything looked gloomy; but where there is life there is hope, and they that have an old Orange tree with but a faint spark of vitality about it, have nothing to do but give it some cocoa-nut fibre refuse and it will recover.

The Orange tree in question is a dwarf variety, name not known, about 3 feet in height, and as much through, branches close to the pot, even hanging over, altogether forming a compact bush. It blooms freely about the beginning of April in a greenhouse; the flowers are whitish, inclined to rosy. The blooms set freely, and two years ago it had thirty fruits upon it, but although highly perfumed the fruit is watery and neither sweet nor acid. It evidently is either a seedling or a cutting, but I think the former, as it is spiny on the branches, and the root not like that of a cutting. It has a tap root like a seedling. I understand it came originally from the Horticultural Society some twelve years ago.

I have read that Orange trees raised from seed never bloom until they cease to have spines on the wood, but depend upon it it is all fudge. Moreover, it is a general notion that Orange trees never produce fruit in this country worth eating. However, those having a viney with a pit inside may grow that fruit to perfection. I speak from experience. I know two trees on four-foot stems, with heads 8 feet in diameter, that annually produce from fifty to sixty-five fruits each, varying in weight from 8 ozs. up to 12 ozs. They are the Tangerine variety. Also, Lemons were grown on the back, 6 ozs. to 13 ozs. in weight, and a Shaddock with larger fruit still.

But about refuse. It restores the impaired constitutions of sickly *Camellias*, entirely removes the variegation on their leaves, and it promotes healthy root-action. *Begonias* like it, *Azaleas* thrive well in it, and *Gloxinias* become half shrubby.

Lastly, this cocoa-nut fibre refuse is just the thing for us small boys—Ah! or you big guns either, to keep a weak plant in good health, or to restore one having a worn-out or nearly exhausted constitution.—GEORGE ABBEY, *Gardener, Horton Hall, Bradford.*

ROSES IN EGYPT.—The following extract of a letter from a Rose-amateur living at Alexandria, dated January 26, 1862, will probably interest some of your readers.—T. R.

"No Rose which I have introduced has succeeded so well

generally as *Souvenir de la Malmaison*. One of the Tea Rose trees I received from you, has this winter produced the best blooms of *Saffrano* I ever saw. Homer is also a perfect show in the garden of a friend to whom I presented it."

CONVERTING A VINERY INTO A STOVE.

A VINERY is well adapted for a stove or hothouse, but, unfortunately, only the upper part of the lights are made to open, the lower ones are fixtures: therefore the Vines cannot be turned out during the winter. It would be a great matter to be enabled to use this house as a stove or forcing-house. As there is a greenhouse it is almost useless except for Vines. What would you advise? What is the highest temperature Vines will bear during the autumn and winter?—A YOUNG GARDENER.

If you had given us a cross section of your house we should have been able to advise you better. The temperature of Vines at rest in autumn and winter should not be above from 40° to 45°. Your best plan would be to have a glass or boarded partition in front, in which to place your Vines in winter, with a few ventilators to the external air to keep the Vines as cool as you like; and ventilators also in the partition to let air into the house when desirable, and also heat from the house to the Vines to break them gradually. If the Vines are at all young, and planted at the front, a couple of feet or so would hold them in the winter. A glass partition would be best; and, if at all wide, could be made moveable, and serve other purposes in summer. The particular mode depends on the construction of the house, but there need be no difficulty.

WORK FOR THE WEEK.

KITCHEN GARDEN.

Now that the weather is favourable for the purpose, clean and stir the ground between the rows of Lettuce, young Cabbages, autumn-sown Onions, Garlic, Shallots, and other such crops. Clear the ground of all litter. Turn and roll the walks, if necessary, for the destruction of weeds, or where they have been loosened-up by the winter. *Beans*, *Broad*, make another sowing. The *Longpod* is a prolific sort, but the Green Windsor has the best appearance when sent to table. Earth-up the early crops. *Capsicums*, pot-off the young plants as soon as fit and place them in a hotbed-frame; they are very liable to the attack of green fly, which should be avoided as soon as possible. *Carrots*, get in the main crop if not already done. The old Early Horn is an excellent sort both for early and late use, as it keeps equally well with the long sorts, and is much better suited for some soils than the others. *Cauliflowers*, the plants raised in heat to be pricked out on a light hotbed; the gentle bottom heat will greatly assist in pushing them along without being drawn, as it is termed, which is the case when they are grown under glass. *Celery*, prick out the early-sown into boxes, or on a slight hotbed. When it has taken root give it air at every favourable opportunity. *Jerusalem Artichokes*, if not yet planted no time should be lost in getting them in. *Kidney Beans*, put in a small breadth of some early sort on a warm, dry, sheltered border, and plant a quantity in small pots to be raised in a cold frame, and planted out as soon as all danger of frosts is over. *Lettuce*, some of the best plants that have been wintered in frames may now be put out—some under a south wall, and others in a more open situation. *Mushrooms*, when they are grown by fire heat a constant moist atmosphere should be kept up by pouring water on the path, or placing pans of water on the flues. Heat of the house when bearing to be about 60°. *Onions*, sow the main crops; if large ones are required plant the very small bulbs of last year, or the autumn-sown plants in rich soil; and still larger may be got by well treading the ground, and laying about 3 inches of very rotten dung upon it, sowing the seed on the dung and covering it with a little fine earth. *Peas*, stick the early crops as soon as they are earthed-up. A few small beech boughs with the leaves on and to be stuck on each side of the row to protect them from frost and cold winds. *Parslane*, make a sowing on a warm border. *Radishes*, sow for successional crops. The Turnip-rooted may now be sown. *Rhubarb*, it may now be forwarded by placing a hand-glass over the roots; a little litter to be placed around the bottom of the glass to prevent the ingress of cold. *Savoy*, make a good sowing of the Dwarf Green, which is a very good old sort for

general purposes. *Salsafy* and *Scozonera*, sow in drills from 9 inches to 1 foot apart.

FLOWER GARDEN.

This is a good time to sow a good collection of hardy annuals. A mixture of some of the hardier sorts, such as *Collinsias*, *Clarkias*, *Eschscholtzias*, *Candytufts*, *Nemophila*, *Mignonette*, *Sweet Peas*, *Corn-plant*, &c., sown over the open parts of the shrubby-borders would give them a gay appearance. Take advantage when the ground is dry to stir the surface of the shrubby-borders before sowing the annuals, or to give the whole a fresh and clean appearance. Walks out of order to be turned, and, if necessary, fresh-surfaced with gravel. The planting of herbaceous plants should now be completed without delay, and the beds or borders they occupy dressed with fresh soil. China, Tea, and Bourbon Roses, if not already pruned, ought no longer to be left without that essential attention.

FRUIT GARDEN.

See that recently-transplanted trees are not suffering from want of water. This, however, will hardly be necessary if the late heavy rains we have had in the neighbourhood of London have been general; but on dry porous soils their roots should be mulched with decayed leaves to preserve them in a uniformly moist state. Attend carefully to the protection of the blossoms of all fruit trees; spruce branches, when nothing better can be procured, will be of service, taking care that they are so fixed as not to be liable to blow against the blossoms.

STOVE.

Proceed with the repotting of such plants as require it. *Alamandas*, *Clerodendrons*, *Isoras*, and other such plants that are well rooted and established in their pots, to be supplied occasionally with some clear but not over-strong liquid manure in a tepid state, to obtain strong short-jointed wood. It is necessary to keep up a vigorous root-action and give a place as close to the glass as possible.

GREENHOUSE AND CONSERVATORY.

Proceed as diligently as possible with the potting of such of the hard-wooded plants as require it, to afford them the advantage of the spring season for making a vigorous growth. Be careful before potting to have the ball in a moist state, and avoid giving large shifts to weak growers. If the *Camellias* done blooming are now started into growth the wood will be ripened early, and by such treatment with the ordinary attention they could be bloomed in November, when their flowers retain their beauty much longer than in the spring. When *Fuchsias* are intended for large specimens they will require a liberal shift, and the smaller specimens established in their pots would be benefited by an application occasionally of clear liquid manure. The *Cinerarias* for late blooming to be shifted. Continue as the *Heaths* go out of bloom to prune them back, and when they have started into fresh growth give them a liberal shift, using good turfy peat for the purpose. Pick off all decaying flowers and leaves, and endeavour to keep the conservatory gay with plants in bloom, placing them in the best positions for a pleasing effect by arranging and displaying the colours to the best advantage. Look for insects, and destroy them as soon as possible. See that the plants in the borders of the conservatory, now that they are getting into active growth, are not suffering for want of water at their roots.

PITS AND FRAMES.

Sow tender annuals and a few German *Asters* on a slight heat. German and Ten-week *Stocks* to be sown in fresh soil in a cold frame or one that will soon cool down. Give bulbs plenty of air, and also all half-hardy plants. Pot the suckers of the different sorts of *Lobelias*. Follow up the matter of propagation, and see that cuttings of young stock are carefully shaded when necessary. The (*Ethiopia missouriensis*) is a good mass flower. Two or three strong old plants taken up now and introduced to bottom heat will produce plants enough for a large mass at bedding-out-time, to be struck like *Dahlias*. One plant will yield thirty or forty cuttings, which will strike in a fortnight or three weeks.

W. KEANE.

DOINGS OF THE LAST WEEK.

SEASONABLE WORK.

THE weather has been too wet and drizzly to do much on the open ground. In light soils it does not so much signify, but if

soils are at all stiff, approaching them when wet, by digging, trenching, or turning, is worse than labour thrown away, as ground moved in that state hardly ever gets kindly all the season afterwards. Just so as respects sowing: the seed to a great extent is lost, the soil clings round it, sealing it up hermetically from air and its oxygen, and even the fertilising rains do not pass freely. If soil is worked when dry, and seeds are sown then, no common amount of rain will ever consolidate the soil afterwards, so as to keep air from the seeds. If seeds must be sown on the ground when wet, in a garden, a dry covering should be given. It is best, however, to defer until a dry day gives a hazely soil.

Used the drizzly days for patching and mending old sashes that are useful in laying over turf pits at this season for bedding plants, a small rail being laid down back and front just to keep the ends of the sashes off the ground; washing thoroughly every spare pot, turning *Geraniums* into turf pits to get at the pots, and washing them, as every pot almost of moderate size is washed half a dozen times from February to June, after which stacks of them are kept for a wet day. To show nothing need be lost, a man to-day has been making propagating-boxes out of old zinc troughing that was worn out, unfit for conveying water. It is mostly about 4 inches or 5 inches wide U-shaped, and being broken through with a blunt chisel into lengths of about 3 feet, a piece of wood is fixed into each end by a tack, and they are then first-rate propagating-pans to set in a hotbed. I was also much pleased with the man that first turned this useless stuff to account, in the way he got ends to slip in. He pitched upon a Larch tree or pole of the requisite diameter, sawed off pieces about 1 inch wide, chopped the piece in two, and one cut thus closed up both ends. The ends not being very tight, and the holes in the zinc that rendered them useless for spouting, made them just the thing for propagating-pans. When I have evaporating-pans made of zinc to place over hot-water pipes, they, too, when worn out make excellent pans for *Lobelias*, *Verbenas*, &c., for several seasons. I know of no plant that would not prefer zinc to crockery-ware; but I do not think that zinc would last long for such a purpose, the plants feed on it so much.

FLOWERING PLANTS.

Sowed a good many flower seeds, as *Lobelias*, *Petunias*, the new kinds of *Indian Pinks*, as *Heddewigii*, *incinatus*, and also, *Capsicums*, *Chilies*, &c., placing all these in heat; also, *Pansies*, *Auriculas*, &c., along with *Love-lies-bleeding*, and *Prince's Feather*, to be early, and placed them in a very mild heat under glass. We will defer *Stocks*, *Asters*, *Zinnias*, &c., to the end of the month, but those who can manage to give them room may sow now. There are many of these things that do better if they never receive much check. Most likely we shall sow in a slight hotbed, and prick off and protect with calico. Were we sowing in the beginning of March, the plants might be injured, because we could not afford to keep them under glass. Most of them, especially *Zinnias*, these grand-coloured old things hardly ever forgive rough treatment, or being knocked about before they are finally transplanted, and this can rarely be done before the end of May.

There is much depends on sowing. We generally fill the pot half full with drainage, then half with rough compost, then finer, and then a layer finer still. This is gently pressed with a round board and a nail in it. The seeds are then sown, and the soil dust-like ones as *Lobelia*, *Calceolaria*, *Clintonia*, *Tobacco*, &c., have just the slightest dust of soil fine-sifted, and white sand thrown over them, and pressed again. All these small things we honour with a square of glass being placed across the pot, and when extra care is required place a piece of paper over the glass. If the soil is rather moist it will seldom be necessary to water before the seeds are up, and in watering such little things no rose should be used, but the water should be gently poured on a crock or cistern-hell in the hand at the sides, so as to flood the surface of the pot without any dashing from a rose.

SOWING ANNUALS.

We have had several inquiries about sowing flower-seeds in borders and flower-beds. All the North American annuals, and all hardy annuals, may thus be sown; but if not sown in autumn little will be gained in sowing before the end of the month, unless in warm and dry localities. To make the most of annuals in grouped flower-beds, we decidedly would always transplant rather than sow, so as to have full, regular, well-formed groups. Suppose you could cover a piece of a border

now with old sashes, mats, or calico, and the border was in fine order, drills might be drawn 5 inches apart, a little rough-riddled leaf mould thrown in, soil placed on that, the annuals sown thickly, and then covered properly; by the end of April you could lift these and plant them in little patches with scarcely ever feeling the moving, and then you might make sure of having regular beds.

Several inquiries have been made to Corastium tomentosum forming a good edging by planting rootless slips now 6 inches apart. We did so four years ago, and never had a better edging. Besides, the keenest amateur may depend on what Mr. Thomson said in a late Number, as he is not the man to conceal any secret in the matter. A lad planted some tit-bits about 1½ inch long in a border before Christmas, and I find there is scarcely one that is not rooted. Complaints have also been made of the variegated Arabis being difficult to strike, but in autumn and spring it strikes freely under a hand-light, and I find that some hundreds of cuttings put in the open border at the same time as the Corastium, are now rooting nicely. These cuttings had no protection but a few spruce boughs laid over them in severe frost.—R. F.

TO CORRESPONDENTS.

* * We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the "Journal of Horticulture, &c.," 162, Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

We cannot reply privately to any communication unless under very special circumstances.

VERBENA PERLE KING (An Amateur Gardener).—Although this Verbena was sent, recently, to be the best of the colour in answer to a correspondent, it will not make a hot bed by itself worth looking at. It must have a white or scarlet along with it to bring it out.

EGENIA UGAI (Old Nurse).—In your northern position we would keep Eugenia Ugai in the greenhouse in winter, and in the orchard-house in summer. Grow in rich soil, loam, and a little leaf mould.

OLD ESPAÑOL APPLA AND PEAK TREES (Rev. E. C.).—These bearing only at the ends of the branches. If the trees are strong late and ripen, or out-pipe them. If this would be too much, and there is no lack of vigour, thin out the spurs and train in young wood either backwards or downwards. If there is a sign of weakness thin the spurs, and manure, especially at the surface.

TRIFOLIUM AND VIBURNUM (A Constant Reader).—We found no insects, but traces of where there had been, and we think some eggs of a beetle. The black granules we attribute to too much moisture at the roots, and not enough of air in this dull weather. We would smother with tobacco to make sure. Place sulphur on the outlet part of the pipes, and give more air.

STARTING ASPENS AND LILACUS (Kate of Ashford).—The best time to sow the seeds for the first time is about the middle of April, but they will not bloom quite so soon as you wish. In July the best time for sowing Petunias seed, which must be done in a mild heat, is any day from the 1st of February to the 1st of May, when one can spare the room for the seed-pots, and by the pots of seedlings as soon as they are fit to be potted down. But say the first week in May is moderate in temperature.

NECTARINES FOR HARGREVE (H. W. Williams).—There seems to be a want of reciprocal root-action. Before the fruit appears, as in fruiting state, give the trees a good soaking with water manure, and water pretty freely, but not all at once, with water at from 60° to 70°. You do not say what the Nectarine is. Some kinds require care to keep the skin from cracking, as in such tender kinds the supply of air is too great for the fruit. Such is often the case with the Spanish Nectarine. You may plant double Guelph now.

BUTTERFLIES IN A PASTURE (A Subscriber).—There are many species of the genus *Vanessa* confounded commonly under the general name of "Butterflies." Your pasture being dry, and if the plant emits summer, it is, probably, *Vanessa urticae*, or *Crepusia* *Crataegi*. There is no mode of destroying it that we know of but piling of the soil where it grows, 6 inches deep, and turning it, leveling the soil, and sowing the bare places with grass seeds.

CAERULEA SLEDEBERG (J. A.).—The blue flower and the flower with white petals narrowly edged with purple are inferior to many of similar colours; but the third flower deserves to be bred from, the colour is new and approaches to a light mauve.

ASPEN (Elmwood).—You will see an answer to another inquirer to-day. In your case we should remove the ant-hills, and sprinkle gum thickly over the places where they were, or water them with ammoniac liquor from a gourd. Repeating the application several times will effectually drive the ants away.

BOOK (G. Baker).—The cost of "The Science and Practice of Gardening," free by Post, is 3s. 4d. You can send either postage stamps, or a post-office order.

WORMS AND ANTS ON LAWNS (G. R.).—The worms can be banished by occasional waterings with lime water; and the ants by sprinkling gumo over their haunts.

CUCUMBER PLANTS DECAYING (W. G. M.).—The fungus you sent is the common Mush-room; it has nothing to do with the failure of your Cucumber plants; the stems of which are decayed, we think, by the excess of moisture in the air and soil of the frames, and want of ventilation.

WHITE MITE ON LETTICES (Boots, L. B.).—It is *Acarus horrescens*, the Garden Mite, and does no harm; it only feeds on the delicate vegetable matters. The roots of your Lettices had decayed from exposure to cold and wet, and then became the appropriate food of the *Acarus*.

EDGING FOR KITCHEN-GARDEN BEDS (T. C.).—Nothing will look neater and better if it is the "cheapest" edging than white bricks laid with one of their angular edges on the summit of the edging. See our description and drawing of it as employed in Linton Park Gardens, No. 2, page 478.

BOOKS (E. L. B.).—The pamphlet you refer to, and which *objects* to form part of our series of "Manuals for the Many," is quite unconnected with our office.

WANT PLOT (An Old Subscriber).—We would make a ridge-and-fur row 40 inches of that open space, the ends of the lines facing the drawing-room window and the Society's greenhouse; that is, plant a row of the *Silvia* down the centre, and let the rows on each side of the centre be the same as the plants. The best way to put in these rows is the way you think best, because you cannot break the principle any way.

WALTONIAN CASE (F. L. W.).—No. 359 of THE COTTAGE GARDENER, which contains drawings and a description of this Case, is out of print; but we will have the article re-written, and published in an early Number of our Journal.

HOT-AND-SLOW (A Constant Subscriber).—An answer is given to-day to an inquirer with a different signature.

FLOWER GARDEN (Editor).—The beds are all properly planted according to the design. We would not wish to change a single plant there.

CELINE FOREBRIER ROSE (Idem).—A capital Rose to run over a good space of wall, and not be long about doing so. The Shanghai Rose from the Hort. Soc. is better, but we have not seen, and know nothing of it. But if it was really very good we think we should not be ungrateful so long.

FLOWER GARDEN (A Subscriber).—In the first place never assume such a general name again. Every one who buys our Journal is a subscriber, and suppose ten such most absurd names came in the same week—why, we might put them in a hat, toss them for the answers, then your answer might be "Never say such a word of a thing," whereas your plan is the very art and mystery of planting, and the best place for such a name is in the name of a pure and simple pronounced style, and you have done it better than it is done in any public place we know. Do recollect about the "A subscriber." Mr. Froben answered your question long since about the way he intended to heat his house, and you have spent your money on your Vine.

PROMOTING VARIETATED ARABIS (Editorial).—It does not come from seed; and, if it did, the seedlings would grow, of course, but variegated but plain green; and plain people, without being green, ought to know and to remember that no kind or sort of variegated plant ever came true from seedlings and not from cuttings. Another peculiarity of this most hardy and most useful plant is, that it is propagated in the spring. The way to do it is to divide the plants in October, to make cuttings of the best shoots first, and plant them out in the open ground with or without a lead-chest; and, if with a glass, to mind to cover the plants with some protection as *Camellia* plants during the winter—water that is, the glass to be lifted for giving air every day in the whole time; and, if no glass is ever there, to see the frost does not throw them out of the soil. We must repeat, beware of spring propagation, as then the plant does not naturally root, to make a cutting of any plant at that critical period, is not only an unnatural process, so to write, but a most unscientific process to the bargain.

TRITONIA GRANDIFLORA (J. T. Stokely).—You must try again. You did not manage your plant at all right, or according to what has been given over and over again in these pages as the right way of treating it. It is an evergreen bog or marsh plant, very nearly hardy. Tritonia arva is just the same, with a similar habit of growing, and a more delicate flower. You may anchor plant very near to them in its requirements, but will stand more hardily. There are ten thousand people in England who could not grow this *Valloia*; and there are seven or eighters out of every seven and twenty who do not know how to grow the Tritonia arva, without being covered by the roots of the red spider, so you are not to blame at all for your *Disa* being a "dizzy" to you as yet. We had a long conversation at the show the other day with the gentleman who brought it to perfection, and he finds it now just as easy to do as a pot Crocus. He has it from seeds as freely as *Calceolarias*, and he is very easy to manage. He says that the seeds of his wandering habit of *Disa*, as soon as the seedlings make four leaves, they begin to make root-runners exactly like Tritonia arva. As soon as he can lay hold of these seedlings he picks out, just like *Lobelia speciosa*, and keeps them in a pot, as you do, until they are ready to stand on their own feet, and he put the pot in a bigger pot which had no hole in the bottom, and which had been kept full of water to run that day to this. The plant was out of doors to October, and nothing ever looked better and more healthy out of water than that very plant. Next May he is going to make an island in the lake-like place for lots of his young *Disas*, as they do the *Melancholias* on the lakes in Cashmere; and anybody could do the like with a couple of peat trays, a few skewers, and an old washing-tub, and let the island and the *Disa* float about as the wind goes, with an umbrella-like covering over head of spun new tiffany, as *Disa* does not like strong sun. Your plant is scathed, nothing else.

CAERULEOLA CUTTINGS (Er. Von Mollat).—The red dust on the lower leaves in your cold frame is a fungus, caused by too much dust. Dust the leaves with flowers of sulphur, and ventilate more freely.

CAERULEA DOES NOT OPENING (J. E.).—You do not tell us where the plants are growing. We should think the failure arises from too much moisture in the air of the house and too little warmth.

EARLY-SET POTATOES.—*An Amateur Gardener.*—My most successful potatoes this year is a better sort we plant in November 8 inches deep, and grow only such varieties as ripen by the end of July. Earliest—commencing the ripening a fortnight. The earlier of Potato ripens later it is from the upward. Last year I planted the same variety, and the same sized sets on the same day, and cultivated his on a way; at taking time to weigh the produce, and that will be the best test. You had better visit some horticultural machine-makers, and select a garden engine for yourself. They are all efficient, and the cost of consideration is the price wished to be given.

VASE PLANTS. *D. C.*—The best plan would be to have small young plants of Tom Thumbs Geranium put in the centre of the zinc pan about the middle of April, to keep it in a cool pit full planting-out time in May, and in the last week in April to plant round the Tom Thumbs such trailing hardy plants as would suit. We only know of two such that will meet this particular case—the *Non-sweep*, and a small trailing yellow *Gladiolus*. Both these ought to be of fresh-divided mid-ribs in little lots, and to be planted quite thickly close to the edge of the zinc pan. It that should not meet your views, or the ideas of many others who may be looking out for filling vases and rustic baskets this season, the next easiest plan to get and to answer would be the fine *Tricolor* Geranium, or even the white one, for a dark bronze vase. In that case, the two *Geraniums* would need to be planted at the same time. It is an excellent plan to have zinc pans to put into vases, instead of filling the vases with the soil. The vases all over the Crystal Palace garden have such pans.

COCA-NUT REFUSE FIBRE. *(D. H.)*—It is not the right refuse. No *Thunbergia* should come in your letters.

NAMES OF PLANTS. *(H. R. E.)*—It is very common; *Orethia maculata*, or Spotted Orchis. *(A. King.)*—Some Labiate, probably a Mint, but we cannot name such a specimen, a mere scrap of drawn-up leaves, covered too, as it is, with the cotton wool in which it was wrapped, the worst of all packing. *(J. G. G.)*—You must really grow your Fern a little larger before we can discuss its name with any confidence. It may be a very young *Cystopteris*, but it may be almost anything else. If we were to guess at it, we should say a seedling *Cystopteris*.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

POULTRY, &c., SHOWS.

KEEPING USEFUL AND ORNAMENTAL BIRDS.

The formation of societies in England and on the continent, having for their object to encourage the breeds of useful and ornamental birds, and to render us familiar with those brilliant colours that have heretofore only been seen by most people after they are stuffed, proves the interest now taken in the different branches of ornithology. There are such exaggerated notions of what is necessary to enable the lover of these things to indulge his hobby, that we think we shall be doing well if we endeavour to make the pursuit easier.

In this as in other things, it is well to begin with moderate ideas, and not only so, but it is well to fix a limit as the fair boundary of ambition. Just as a man is not deterred from buying or renting a small place, because he will be in the neighbourhood of large domains; even so, he need not be discouraged, or prevented from entering on the pursuit of natural history because it embraces so large a field. The owner of the small place may improve or enlarge his property as prudence may allow or opportunity suggest, and in like manner the student or amateur may increase the number of his subjects as occasion presents.

People who walk about London seeking amusement, and who look in the windows of the various shops, may have remarked that, and laughed at afterwards, the trays in some of the city jewellers' shops. They contain numerous articles, and generally in the centre a bouquet of diamonds, or a startling hoop of emeralds and brilliants, and there lies close to them a ticket on which is written, "Articles in this tray from 3s. 6d. upwards." Desire looks at the cluster, the bouquet, or the hoop. They cannot be the 3s. 6d.; then it sobers down, and wonders which can be. When the article is shown there is some wonder how it can be made for the money; then there is some doubt whether it is real; and then there is admiration. The fact that it is ours gives it a charm that nothing belonging to another can possess.

Much of this applies to natural history. The great charm of keeping birds or animals is to do so without interfering with their habits; hence the desire to possess such as will breed. To this may be attributed the old, old, fancy for gold fish in a globe. They are uninteresting, and as a rule they know no one,

not even the hand that feeds them. We view the aquarium as an animated book, and any appeal to the feelings, is rather to intellect than anything else.

These, however, can be indulged in, in any house and under any circumstances. Having to do with more active, or, at least, more interesting, and we think more beautiful specimens of animated nature; and having at this time an Australian Crow by our side, which is doing his best to make this paper too late, first by crowing, then barking, then miaowing, and then whistling, "There is nae luck about the house," while a Silver-cock Pheasant drops his gills, raises his crest, stands on tiptoe, à la Zappertit, and beats his breast with his wings, à la Gorrilla; and a whistle will bring twenty Ducks around us. We find so much pleasure in these things, and we are so convinced they are within reach of many who are not aware of it, that we are disposed to put on paper that which is our practical experience of it, showing how easy it is to make a beginning.

While we speak of these things, apparently to those only who live in the country, yet many London houses afford all that is necessary for keeping Pheasants and Wild Fowl. A small back yard will make a plesantry. A cock and three hens may be kept well, and will lay and enjoy themselves in a place 9 feet square. A building like a sentry-box will give them all the shelter they require. It would have to be provided with perches, and there must be no flooring. The stones of the yard must be removed, and part of the space gravelled. A little lime and some dust must be put in, and it will be a great luxury if a small tree or shrub can be sunk in a large pot in the earth. The space that can be spared for these beautiful birds must be fenced with galvanised wire netting stretched on framework, and slight deal boarding should be put around to the height of 18 inches. It prevents the birds from being frightened, and takes from them the desire of trying to get out, whereby they often spoil plumage by pushing their necks through the meshes of the wire netting. They require only dry food, a little corn or bread. Their water should be kept in one of the fountains now so much used. Pheasants are especially London birds. They are handsome, bold, very hardy, do not suffer from confinement, make no noise, and emit no odour in the hottest weather. The Golden, Chinese, and Common are the best suited for a London atmosphere. The White, Silver, and Pied show the smoke. It adds much to the pleasing appearance if creeping plants are allowed to run over the netting in summer. But for instructions in gardening our readers must consult the horticultural part.

(To be continued.)

TAUNTON AND SOMERSET POULTRY ASSOCIATION.

We have much pleasure in stating that this flourishing Society purposes holding its second annual Exhibition on May 14th and 15th, and we doubt not it will receive from exhibitors of poultry the confidence it deserves, by their making a large number of entries for the valuable prizes which will be offered. We have the prize list before us, amounting altogether to nearly £100 (Poultry and Pigeons). Besides the money prizes we notice that there are "fourteen pieces of plate," value £2 2s. each, and three silver medals to be awarded, and we understand these pieces of plate (which will be displayed at the time of the Show) are selected by the Directors, so as to combine the useful and ornamental. We have often heard the remark from successful exhibitors, that "they are tired of receiving silver cups," and to judge by the appearance of many side-boards we have seen, there is some ground for such a remark. The articles given by this Society last year comprised cake-baskets, handsome ruly and ground glass vases, salvers, tea and coffee pots, fish-slices, and forks in cases, spoons and forks of all sizes, ink-stands, &c., and we are authorised to state that a similarly valuable assortment will be displayed on the occasion of the forthcoming Show. When we add that these prizes can be secured by the very moderate entry fee of 4s., and that every prize is guaranteed to be paid (as was the case last year) the week after the Show, we feel certain the Directors will not have to complain of a want of entries for one of the best-conducted Shows in the kingdom. The classes are—Spanish, Dorking (two classes), Cochon-China (three classes), Malay, Game (three classes), Hamburg (four classes), Poland (three classes). A class for Pea fowl, Pheasants and Gallinas, and "any other

variety," separate classes for each breed of chickens; Sweepstakes for single cocks of every breed, including a special sweepstakes class for one hundred Game cocks with a first prize of £20, six classes for Dantams, four for Ducks, and also for Turkeys and Geese. The Pigeon classes are fifteen in number, and there are three prizes in every class in the list. We observe that pens, 6 feet in length, will be provided for Pea fowl, Pheasants, Turkeys, and Geese; and that most of the roadways in connection with the south and west of England have liberally consented to convey poultry for this Association at a single fare for both journeys. We must refer our friends to the schedule itself for further particulars, and conclude our remarks by stating that Charles Ballance, Esq., of Taunton, still continues his services as Hon. Secretary. His name has long been known in the poultry world as a devoted amateur, and latterly as a judge at some of our principal exhibitions; and we are sure that under his management nothing will be wanting to secure the well-being of the birds, and the satisfaction of their owners.

LIGURIAN BEES.

DID not the Apian Society obtain some of the Italian bees two or three seasons ago? Have any results been made known? Would it be possible to keep the two varieties of bees distinct on the same place? Where could I and my neighbours obtain some good strong hives to begin with?—*ARIS MELLIFICA.*

[In the autumn of 1859 M. Hermann sent me two queens than Mr. Woodbury could make room for, and he sent two of them to Mr. Tegetmeier. Both died in the winter. Next year (1860) Mr. Tegetmeier, Secretary of the Apian Society, had two queens from Messrs. Neighbour, but we do not know the result. The Society is, we imagine, defunct. To obtain stocks of Ligurian bees, write to T. Woodbury, Esq., Mount Radford, Exeter.]

UNITING BEES.

I HAVE had a memorandum jotted down for a considerable time past to write a few remarks on the foregoing subject, but I am pleased to have been forestalled by your able and practical correspondent "A RENFREWSHIRE BEE-KEEPER," who has, I will not say exhausted the subject, but given the results of his experience pretty much in accordance with my own. Without now intending to attempt anything like an essay on this matter, there have occurred to me a few ideas which I should like to express.

I would first premise that, having made very many forced unions of bees during the whole period of my apian career, I can quite coincide with your correspondent in his assertion that there is "no infallible mode of accomplishing this desirable object." Like many other particulars of the art and practice of keeping bees, what is found to answer most perfectly for one, two, or more times, will utterly and lamentably fail on a subsequent trial. For instance, when fumigation was all the rage with me, I scoured the country round for cottagers who would be willing to let me have the bees at taking-up time, instead of their destroying them with brimstone. Having had a box made about the diameter of a common hive furnished with a perforated zinc top as a slide, the fumigated bees dropped into it from among the combs, the slide was pushed in, and by the time they arrived at their new locality were generally perfectly recovered. Sometimes the hive to be strengthened was allowed to remain many hours over the bees in the box, with the zinc between them; but more frequently a quantity of smoke was puffed into the entrance, the zinc carefully withdrawn, and all means of egress closed, perhaps for twelve hours. Very frequently the bees would join as well as could be wished, the loss of life being confined to a few over-dosed or otherwise accidentally-injured ones; but occasionally the sacrifice of life was awful to behold, leaving it a very doubtful point if any increase of strength had accrued to the colony which it had been desired to strengthen. Another plan adopted was simply to put the fumigated bees in a small box about 10 inches by 6 in. high, and 6 inches deep, with a two-inch aperture in the bottom to correspond with that on the top of the hive; the slide was withdrawn, and the bees allowed to unite as they pleased. Although this appears to be a very risky way of attempting the accomplishment of the desired object, yet I do not now remember having had any great amount of fighting. Mr. George Fox, of Kingsbridge in this county, at that time generally adopted this plan.

But where the hives to be taken and that to be the recipient of the fumigated bees stood together in the same apiary, another mode of procedure was invariably followed. Both hives were treated to the fumes of the byssus on their own stands. All the bees that would fall by smoke and with the aid of a little rapping being down from one, the other was inverted with its bottom board, the latter removed, and the bees from the other stock emptied and shaken down among the combs; the bottom board was replaced, and the hive re-instituted in its proper position. As a rule, these junctions proved successful; but occasionally I had to experience the mortification of having been the unwilling cause of a terrible slaughter.

Whether correct or not in the conclusion arrived at, it really appeared to me that the actual gain from the union of fumigated bees was at best but very doubtful in a great number of cases. Many a hive so reinforced in autumn, exhibited in the spring a smaller population than adjoining hives which had been left alone. I once united the bees of five populous stocks, gave them a box of combs, and 10 lbs. of prime honey besides other food; yet they were a poor lot of bees all the next spring and summer, and came to grief in the end.

But I do not find it so with driven bees. Many years have elapsed since the fumigating-tube has been used in my apiary; and, probably, it will never be so applied again. Driving, I quite agree with your correspondent, is by far the most simple, easy, and altogether satisfactory mode of expelling the bees from a hive, and has been the plan adopted by me of late years. I cannot say that the junction of bees by its aid has been so marked by the freedom from disasters with which he seems to have been favoured. I do not remember having ever had a case of the loss of a hive from the death of both queens during the time that fumigation was in use; but more than once has that calamity occurred to me of late. Perhaps it has arisen from over-care in having secured the person of her majesty in a small box, and confining her with a few of her subjects among the combs for twenty-four hours.

I quite agree with your correspondent that the union of bees should be effected in as rapid and decided a manner as possible, and have adopted most of the plans he mentions. Since the introduction of frame-hives into my apiary, it has been my practice, invariably with success so far as the peaceable union of the bees was concerned, to remove the crown-board, and knock out the bees on the top of the frames. A little sprinkling of sugared water has been generally given, and so far as I have seen during summer it seems to be advisable, though by no means always absolutely necessary. A slight odour of peppermint has been adopted with satisfactory results. In this way of accomplishing the object in view, I do not remove more than one queen; nor, in fact, any at all, unless it is desirable to save the life of one in particular rather than the other. The only case of an accidental result of uniting bees by this plan occurred to a valuable Ligurian queen, which was confined for the purpose of greater security. It yet seems a doubtful point as to whether increased safety does attend her confinement. Perhaps Mr. Woodbury, who has had more experience in this particular during the two or three seasons he has manipulated with the Ligurians, will give us his views on this head.

With regard to the union of swarms there is also occasionally considerable fighting and loss; but on the whole I have been tolerably successful. A cloth is spread on the ground, a couple of sticks laid on it; and, the bees of one hive having been knocked down by a vigorous blow on the sticks, the other hive is placed over them, and thus left until the morning. It is quite immaterial whether the hive to be reinforced has been newly peopled or been occupied for some weeks. I find they unite equally well.

One case, however, that I had this last summer puzzled me not a little. All was done exactly as usual; but in the morning the garden was strewn over for many yards thickly with bees, still living, which had crawled away during the night—going to the stock-hive there was none. I have occasionally inverted the hive to be strengthened, and knocked out the other bees into it, mingling all in a most sudden union; but there is some risk to the newly-formed brittle combs, besides the dispersion of the cluster of wax-working bees, which is an evil that ought to be avoided. There does not seem to be the same necessity of a sudden commingling of the rival bees with regard to swarms, as in uniting them to an established stock, particularly in the fall of the year; so I much prefer the plan first alluded to.

No bee-keeper deserving the name should be ignorant of, or

what is much the same thing, fancy himself unable satisfactorily to perform the operation of *driving*. Some few years ago, it used to appear to be an utter impossibility for me to drive a hive successfully; now, there is no operation connected with bee-management which I feel more confidence in setting about, or more easy as to the result. It is the work but of a few minutes only, with hardly a bee left among the combs, unless a few young ones which have just vacated the cells. At all times and seasons, except, perhaps, in the winter; with hives in every state and condition of strength, full to repletion of brood or otherwise, and with or without a queen, have I succeeded in this operation. My plan being precisely that so ably given by your correspondent, nothing remains to be added on that head. Nearly all the swarms I have had this last season, were (as described in "Apian Notes") artificially made by driving the old stocks; and I never mean, in future, to be subjected to the annoyances and anxieties consequent on waiting for the issue of *natural swarms*. There is one other mode of uniting stocks, which I have performed very successfully within this last week, and which is applicable only to bar or frame-hives. As Mr. Woodbury initiated me into the plan, perhaps he would kindly relate it for the benefit of your readers in these pages; for, in certain matters of detail, he might not act exactly as I did. These remarks have extended to a much greater length than I at first intended, so that further trespass on your space must be avoided by—S. BEVAN FOX, *Exeter*.

BEES AS CHEMISTS.

As all the results of actual experience on a debatable point are extremely valuable, I have to thank a correspondent in Lancashire for the following interesting communication which strongly confirms what has already been advanced on this subject by—A DEVONSHIRE BEE-KEEPER.

"I have been very much interested in the discussion published in THE JOURNAL OF HORTICULTURE on the chemical change which syrup undergoes in the stomach of the bee, as my experience coincides with yours. A few years since I had a late swarm in a very bad honey season, but which I wished to keep, and in September and October I gave them a large quantity of syrup made with ale, sugar, and honey, according to Dr. Bevan's receipt. I afterwards changed my mind, and destroyed the bees. The combs contained about 15 lbs. of honey, which were eaten for breakfast. In the comb, one of the family (a strict total abstainer) declared that he could detect the taste of beer. My sister and myself could not perceive it—at any rate the change was very great, as the syrup, before being stored away by the bees, had an unmistakable flavour of ale.—J. L."

[We cannot admit that this is an evidence that syrup is converted into honey by the action of the bee's stomach. In the first place, one witness states that he could taste the beer, and in the second place it is only a reasonable conclusion that the 15 lbs. were a mixture of honey collected by the bees, and of the sugar and beer supplied to them. The point will not be conclusively decided until a swarm is hived, placed in a room immediately, and supplied with plain syrup only.—EDS. J. of H.]

IS FUMIGATION INJURIOUS?

INOFFENSIVENESS OF LIGURIAN BEES.

BEING a timid bee-keeper, and, moreover, possessed of but little spare time, I wish to inquire if any of your readers have had any experience in fumigating, and if they have discovered any bad effect upon the stocks or injury to the queen's fecundity by the process. I have several hives whose fabric is in anything but a desirable condition, but which are otherwise strong and healthy; these I wish to Ligurianize this summer from a strong Ligurian stock I have. With my small amount of time (being absent from home all day), and limited experience, I fancy this would be best accomplished if I can now soon transfer the contents of the existing hives into bar ones; but I fear I could only manage this by fumigating, and I should be loth to do this if it inflicted a permanent injury on them.

A good deal has been said respecting the superior qualities of the Ligurian breed, but a not unimportant one I do not recollect to have seen noticed—viz., their shyness in using their stings, and the comparatively little pain produced when they are used. On unpacking a stock of Ligurian bees after a journey from "A

DEVONSHIRE BEE-KEEPER" (and therefore they might be supposed to be somewhat vicious) I was immediately covered with them, being quite unprotected at the time, but I received not a wound until I violently crushed a number on the back of my neck, and then I was stung by thirteen of them. The effect, however, had quite disappeared in twenty minutes, whereas one application of the sting of a black rasnal disfigures and pains me for two or three days. I have several times brought Ligurians to town with me (eight or nine miles) in my clothes, and occasionally they have remained about me while at business for a whole day, and have even returned with me at night, being perfectly lively at the time and myself unconscious of their presence till informed of it by other persons.—GEORGE F. BARRELL, *Colney Hatch*.

"WOODBURY ON BEES AND BEE-KEEPING."

THE interest which has been taken in this country in the natural history and management of the honey bee has certainly not diminished of late years, if we are to judge by the multiplicity of patent and other hives advertised for sale every year in the various periodicals devoted to the encouragement of rural pursuits, or by the books published or articles communicated to the periodical literature of the day on every branch of the subject. It is not to be wondered at, indeed, that in the pages of such a Journal as this, a corner should be devoted to bees and bee-keeping. The wonder would be that it should not; but it does indicate an extraordinary and general interest to be abroad on the subject, when we find a long and elaborate essay on bees in such a periodical as the "Quarterly Review." There is, however, scarcely a serial or review which has not an article on bees. Thus, for instance, we had not long ago an essay from the pen of Professor Leitch in "Good Words;" another in "The Intellectual Observer," on the development of queen bees by —; and quite recently Mr. T. W. Woodbury, of Exeter, well known to the readers of this Journal under the *nom de plume* of "A DEVONSHIRE BEE-KEEPER," has supplied an article on "Bees and Bee-keeping" to the "Journal of the Bath and West of England Society for the Encouragement of Agriculture, &c." This article is before me. It is written in a clear style, and gives all the information which can be desired on the subject, founded on actual knowledge. Mr. Woodbury's experience as a practical and scientific apian, inferior to none in this country, comes out at every page, and shows him to have read largely and observed largely. He has adopted every really valuable recommendation of older or more recent apianians, and added to ancient bee lore much valuable knowledge of his own gathering. The public would gain by the reproduction of this essay in a cheap form, which would admit of its wide circulation among cottage beekeepers. The peculiar merit of the essay lies in the fact that Mr. Woodbury, while hinting at many improvements, carefully avoids recommending anything that would induce the cottager to run risks by a too scientific treatment of his bees.

The article opens with a brief account of the natural history of the honey bee. Then follow a series of remarks on "The Swarming System," "Autumnal Unions," "Driving," "Union of Stocks," "The Depriving System," including collateral and storifying management, with a full account of different sorts of hives, both straw and wooden, bar and frame, single and compound, and, in short, everything that modern science has to tell about bees and their management. The article concludes with a chapter on the so-called "Ligurian bees" (more properly Italian), which Mr. Woodbury has, I believe, introduced into England. It appears, by his statement, that nine stocks which he had at the close of 1860, were multiplied as follows in 1861:—

Ligurian queen bees despatched to various parts of the kingdom ...	10
Ligurian stocks sent to a distance—one as far as Hull,	16
Ligurian stocks and swarms remaining in my apiary,	26
Total,	52

The concluding passages will be read with interest by all who wish well to the introduction of this bee into Great Britain.

"Although I had no intention of rearing any honey harvest, I have had two supers of beautiful honey, as it were, forced upon me, one of which weighed 26 lbs. and the other 38 lbs. nett."

"From my strongest Ligurian stock I took eight artificial swarms in the spring, besides depriving it of numerous brood-combs. Finding, in June, that the bees were collecting honey so fast that the queen could not find an empty cell in which to lay

* Only a few years ago.

an egg, I was reluctantly compelled to put on a super. When this had been filled with 38 lbs. of the finest honeycomb I removed it, and as the stock-hive (a very large one) could not contain the multitude of bees which issued from it, I formed them into another very large artificial swarm.

"The foregoing facts speak for themselves; but as information on this point has been very generally asked, I have no hesitation in saying that I believe the Ligurian honey bee infinitely superior in every respect to the only species that we have hitherto been acquainted with."

This testimony in favour of the Italian race is certainly important; but some years must elapse, giving time for careful reports from various quarters, before we can speak positively as to the relative merits of the English and Italian bees.

In his note on "the swarming system," Mr. Woodbury observes very truly that it "is very bad economy to destroy old stocks and keep first swarms, as is the general practice in the west of England, because under this system there is no provision for renewing queens whose breeding powers may, and do frequently, become impaired with age, and whose ultimate death is often the unsuspected cause of the loss of what with a young queen would have continued a flourishing colony. The honey obtained from swarms of the current year is also very superior to that which can be drained from old combs, and will always command a higher figure in the market." This ought to be impressed everywhere on the minds of rustic bee-keepers, by all persons who desire pure honey to be sold in the market, and not that brown abomination compounded of the essence of bee-bread and propolis, stale and nasty, which is expressed out of old black combs. A lady friend of mine last autumn accidentally discovered what "honey" too often really is, having "looked in" at a cottage at the awful moment when the mash of comb, &c., extracted from a "hippen," was giving forth its ooze before the kitchen fire. It makes one shudder to think of it! In this instance, too, the young bees in their white state were contributing their milky juices to the profitable store!

Mr. Woodbury makes use of box-bee-hives 13 inches square, by 9 inches deep. This is an excellent size for general use where the hives stand singly in the open air, under verandahs, or in rooey bee-hives. I can, however, confidently recommend a different shaped box-hive, which I have adopted with great success these two or three years, and which is now universal in my bee-hive. It is a long and narrow hive, uniformly 9½ inches wide in the clear. Ten inches would, I think, be an improvement. It is 9 inches high, and 16 inches or 17 inches long. "Every box should be of exactly the same width—*i.e.*, with a view to the bars (which run across the narrow width), being transferable from one hive to another. In this particular only do I deviate from Mr. Woodbury, whose rule I otherwise emphatically endorse—*viz.*, that "these dimensions" must be rigidly adhered to, as every bar should fit every hive in the apiary. It is a good plan to commence by making a pattern bar of mahogany, which should be taken care of and used as a guide whenever comb-bars are required." My long and narrow hives are thus about equal in space to his, containing somewhere about 1500 cubic inches. The following reasons have induced me finally to adopt this hive:—1st, More of the comb is visible from the long side windows. 2nd, The boxes allow more room for inspection in a contracted space. 3rd, The combs being narrow can be taken out with fewer bees upon them, and are more easily handled than longer and heavier combs. 4th, The breeding-combs are kept more distinct from the store-combs, by which I mean that the inner combs are usually devoted almost entirely to the accommodation of the young bees, while the honey is generally stored in the outermost combs, most distant from the entrance. My top-boards are now made in two or three pieces, each piece covering several combs and being screwed down separately. By this means I do not disturb a whole hive when I want to extract one or more combs in a particular part of it.—B. & W.

(To be continued.)

LIGURIAN BEES IN PODOLIA.

It would appear from the following extract, which is translated from a German letter dated the 19th of November last,

"A three-eight rabbit is cut out of the top inner edge at the back and front of the box, and below this rabbit are holes in which rest the ends of the bars. This arrangement allows the bees free passage above the comb bars, which are 1½ inches long, seven-eighths of an inch wide, and three-eighths of an inch thick.

that the Ligurian honey bee is rapidly supplanting the common species throughout the Continent, Podolia being a government in the south-western part of European Russia.—A DEVONSHIRE BEE-KEEPER.

In Podolia I met with an apiary of five hundred stocks, consisting entirely of pure Italians, the German bees being unknown there. The produce of the honey harvest for the year 1851, was 270 puds, equal to 9500 German pounds.* Therefore, three hundred stocks must have been killed, since we estimate that from this number the above-named quantity of honey would be obtained. This—*i.e.* the old-fashioned plan of killing bees, is, however, the worst mode of treatment that I am acquainted with."

100 German pounds are equal to about 110 English pounds.

OUR LETTER BOX.

BIRD-BED GAME AT LIVERPOOL. (S.—You are quite right as to the superior merits of Mr. Sandford's birds; and we have good reason for believing that he would have been awarded the first prize if his man had not disqualified the pen by sending one hen instead of two.)

QUANTITY OF TOBACCO FEEDING BIRDS (*beginner*).—It is impossible to name the quantity of food. They consume more if they are well in May and June. Feed them by hand so long as they will run after the food; but when they cease to run, you must cease to feed. You will soon arrive at an average, and it will be less than you imagine. Some breeds eat more than others.

BREEDING CAROLINA DUCKS (*beginner de la Vallée*).—The nest for a Carolina Duck is exactly like a semi-duck-pond; it should be 15 inches deep, 12 inches wide, 12 inches high in dependent air; that is, the latter should be of the common shape. There should be an opening as in a kettle, and there should be a head in front to prevent an egg from rolling out. The roof of the hut or kennel should slant to the end for the same purpose, and there should be some holes found to allow any water to escape. It should be fastened on a pole about 6 inches from the highest level of the water, and there should be a ladder from the box downwards; this latter should consist of a plain board, with cross-pieces nailed on for foothold. It is wise to put some of the eggs under a hen. The Ducks hatch them well, but they are not productive.

HOOD-NECKS FOR BANTAMS (*E. Debra*).—We see no objection to this being under large as the run the birds will have "in an open field with a west aspect." They will have plenty of sunlight and air there.

GREEN LAYING SOFT EGGS (*beginner*).—Your black hen Tumbler is suffering from a disease of the egg-passages. Most probably she is too fat. Put her on a low diet, or short commons, with plenty of exercise. Beans contain but little fatty matter, barley even less, and will be suitable for her. Hemp-seed, Indian corn, and such food containing much oil would be very injurious. When next about to lay I think you may give her a gosseul full of castor oil; if given twenty-four hours before the L. Green is expected to lay I have found great benefit from it. Anything that can be done to keep down her fat and subdue the inflammation of the ovifacult will be useful. Fledged eggs will keep good for hatching about a fortnight. Perhaps, if put away in a cool place not damp, nor yet too dry so as to cause evaporation, in all probability they might be kept successfully for a longer period.

AVIARY *Idem*.—If the aviary that contains the Blackbirds, Hedge Sparrows, and Robins is furnished with thick bushes or a hedge of boughs, and the birds are liberally fed they will very likely breed. The Robin with a cream-colored breast is quite a curiosity. You should have exhibited it.

BULLFINCH AND CANARY HYBRID (*Idem*).—Males have been bred from the cock Bullfinch and hen Canary: but their nature and sexual language are so very different that they rarely form an alliance. The Bullfinch is a late breeder, the end of April to the middle of May being their time. I fear they would not succeed well with the other birds, and should prefer trying them in a large separate cage. If they together do get acquainted, they separate them (but where they can communicate), and put them together again at the breeding season.—B. F. BENT.

TENNY-FLOAVORED BUTTER (—).—A quarter of an ounce of salt-petre to two gallons of cream is added to remove the flavour. We do not assert that effects the desired result.

FATTENING CALVES *Idem*.—We do not believe that chalk added to the milk given to fattening weaned calves has any such effect as rendering their flesh white. We think it probable that the milk mixed with skimmed milk could successfully fatten calves. The late Duke of Northumberland prepared skimmed milk with treacle and linseed oilcake; and it is stated that this mixture has been found to succeed (—"Dictionary of Practical Agriculture," vol. 11, p. 287). Here the sugar in the treacle, with the fat and grain of the oilcake. The latter deposits for the cream removed from the milk. Cream, however, contains also a quantity of casein, which is not supplied in this mixture. I raised fat-axed—"Annals of Agriculture," vol. xxiii.) and an infusion of hay ("New System of Husbandry," vol. iii.) have been added to skimmed milk for a similar purpose. In this subject it may be worthy of remark that the only kind of food in which casein exists is that derived from leguminous plants, such as beans, peas, and lentils. When bean-flour is softened and ground up with water, and the infusion passed through a sieve, the water is found to contain casein, fat, butter, and starch. The latter deposits by standing, and the infusion has now all the characters of skimmed milk, as in fact, with the exception of sugar of milk and butter, it is precisely identical with it. The addition of some fatty and gummy matter (as an infusion of linseed-oil) would more nearly approximate it to the composition of ordinary milk. And it is well worthy of remark, that the secret diet of English lambs in many of Scotland, peat or bean soup, is very frequently given to young calves.—"Cottager's Journal," No. 1, 1861.
